## INFORMATION TO USERS

This manuscript has been reproduced from the microfilm master. UMI films the text directly from the original or copy submitted. Thus, some thesis and dissertation copies are in typewriter face, while others may be from any type of computer printer.

The quality of this reproduction is dependent upon the quality of the copy submitted. Broken or indistinct print, colored or poor quality illustrations and photographs, print bleedthrough, substandard margins, and improper alignment can adversely affect reproduction.

In the unlikely event that the author did not send UMI a complete manuscript and there are missing pages, these will be noted. Also, if unauthorized copyright material had to be removed, a note will indicate the deletion.

Oversize materials (e.g., maps, drawings, charts) are reproduced by sectioning the original, beginning at the upper left-hand comer and continuing from left to right in equal sections with small overlaps.

Photographs included in the original manuscript have been reproduced xerographically in this copy. Higher quality $6^{\prime \prime} \times 9^{\prime \prime}$ black and white photographic prints are available for any photographs or illustrations appearing in this copy for an additional charge. Contact UMI directly to order.

#### Abstract

The derivatization of the newly developed preorganized tetraphenol ligand tetrakis(2-hydroxyphenyl)ethene, the coordination chemistry of the derived ligand systems, and verification of their potential as polymerization catalysts are described in this thesis.

Ortho-propylated analogue tetrakis(2-hydroxy-3-propylphenyl)ethene and selectively alkylated $E$ - and Z-bis(2-hydroxyphenyl)-bis(2-methoxyphenyl)ethenes were synthesized as modified ligands of the parent system, tetrakis(2-hydroxyphenyl)ethene. The ability of these ligands to serve as templates for constructing polymetallic coordination complexes, especially hetero-polymetallic species, was examined by using three metal elements, titanium(IV), magnesium(II) and aluminum(III), as potential models of classic heterogeneous Ziegler-Natta catalysts.

The ortho-propylation of the ligand system contributed to the reduced tendency for intermolecular aggregation. Various coordination patterns and chemical reactivity were observed in the polynuclear complexes and were quite specific to the metal and other ligand groups. "All-up" trinuclear structures were always observed for magnesium complexes. "Up/down" dinuclear structures, mostly geminal, were preferred for titanium complexes. Aluminum complexes showed various coordination patterns, from sixmembered crown ring systems to symmetrical and unsymmetrical dinuclear structures, depending upon the degree of exposure to a coordination solvent and the different substituents on the aluminum atoms. Several hetero-polymetallic complexes were also developed, starting from a magnesium complex.

The E-dialkylated ligand exhibited an ability to form well-organized titanium and aluminum complexes. The titanium complexes were all mononuclear, while both mono-

and dinuclear aluminum complexes were obtained. The latter, however, basically consisted of a core mononuclear structure appended to an alkylaluminum reagent through a dative interaction. Attempted synthesis for aluminum/titanium hetero-polynuclear complexes extended our understanding of the ligand's coordination tendency. The $Z$ dialkylated ligand, on the other hand, was found to be a poor template for the construction of discrete metal complexes.

The titanium complexes of these preorganized phenoxide ligands showed poor ethene polymerization activity. Meanwhile, when titanium precatalysts were prepared in situ from the corresponding magnesium complexes, high polymerization activity was observed. The active catalytic species must somehow involve magnesium in the newly formed titanium aryloxide. This "magnesium effect" was not specific to preorganized systems, but also true for simpler phenoxide systems. The preorganization of the designed ligand systems contributed to the narrower polydispersity of the product polyethene.

## Acknowledgement

My sincere gratitude to my supervisor Dr. Jeff Stryker, for support and encouragement, and the colleague Udo Verkerk, who set the basis of this project. Also to the other past and present labmates, especially Dr. Makoto Yasuda for useful discussions and friendship, and Dr. Charles Carter and Dr. Sensuke Ogoshi for teaching various lab techniques in my early years. Many thanks to Dr. Bob McDonald in the X-ray lab and the skilled staff in the Analysis Lab, the NMR lab, the mass spectroscopy lab, the glass shop, and the machine shop. Acknowledgements to the Department of Chemistry and University of Alberta, for encouraging and giving chances to a foreign student with a B.A. degree. Special thanks to Dr. Lois Browne, for care and support in many ways, and my close friends who shared funny experiences as foreign students in Canada. Finally, the best gratitude to my family back in my home country.

## Table of Contents

General Introduction ..... 1
Chapter 1. Ligand Synthesis and Modification ..... 2
1.0. Introduction ..... 3
1.I. Modification of Tetrakis(2-hydroxyphenyl)ethene Framework ..... 9
1.1.1. Ortho-Substituent Introduction ..... 9
1.1.2. Partial Protection/Deprotection of Hydroxy Groups ..... 13
1.1.3. Attempts to Introduce Other Heteroatoms ..... 22
1.2. Synthesis of 2,7-Bis(1,1-dimethylethyl)-9H-fluorene-1,8-diol (4) ..... 23
1.3. Conclusion ..... 25
1.4. Experimental ..... 26
1.5. References and Notes ..... 45
Chapter 2. Preface to Chapter 3 and 4 ..... 47
Chapter 3. Metal Complexes Derived from Tetrakis(2-hydroxy-3- propylphenyl)ethene: Structure, Spectroscopic Features and Chemical Behavior ..... 56
3.0. Introduction ..... 58
3.1. Homo-polymetallic Complexes ..... 61
3.1.1. Mg Complexes ..... 61
3.1.2. Ti Complexes ..... 77
3.1.3. Al Complexes ..... 109
3.1.4. Na Complex ..... 121
3.2. Hetero-polymetallic Complexes ..... 124
3.1.1. $\mathrm{Mg} / \mathrm{Al}$ Complexes ..... 126
3.1.2. $\mathrm{Mg} / \mathrm{Ti}$ Complex ..... 134
3.1.3. AI/Ti Complex ..... 136
3.1.4. Other Attempts to Prepare Hetero-Polymetallic Complexes ..... 139
3.3. Conclusion ..... 139
3.4. Experimental ..... 141
3.5. References and Notes ..... 167
Chapter 4. Metal Complexes Derived from E- and Z-Bis(2-hydroxyphenyl)-bis(2- methoxyphenyl)ethene (3E/3Z): Structure, Spectroscopic Features and Chemical Behavior ..... 169
4.0. Introduction ..... 170
4.1. Al Complexes ..... 172
4.2. $\quad \mathrm{Ti}$ Complexes ..... 182
4.3. Attempts to Construct $\mathrm{Al} / \mathrm{Ti}$ Complexes ..... 192
4.4. Conclusion ..... 202
4.5. Experimental ..... 203
4.6 References ..... 212
Chapter 5. Ethene Polymerization by Derivatives of the Preorganized Polyaryloxy Ligands ..... 213
5.0. Introduction and Overview ..... 214
5.1. Ti Complexes ..... 215
5.2. Magnesium Effect ..... 222
5.3. Conclusion ..... 254
5.4. Experimental ..... 256
5.5. References and Notes ..... 282
General Conclusion ..... 284
Apendices X-ray Crystallography Data ..... 286

## General Introduction

This thesis describes the modification of the newly developed preorganized tetradentate ligand, tetrakis(2-hydroxyphehyl)ethene, the metal coordination chemistry of several substituted ligands prepared, using $\mathrm{Ti}(\mathrm{IV}), \mathrm{Al}($ III $)$ and Mg (II) metals, and trials of the metal complexes in ethene polymerization catalysis.

## Format of this thesis:

This thesis takes a paper format. Each of the major chapters (Chapters 1, 3, 4 and 5 ) is self-contained, having its own introduction, table of contents, conclusion, experimental and references/notes sections.

## Thesis overview:

The synthesis and modification of tetrakis(2-hydroxyphehyl)ethene are described in Chapter 1. The synthesis, characterization and chemical behavior studies of the metal derivatives from the selected ligands are discussed in Chapter 3 and 4: Chapter 2 provides a preface of these two chapters. Ethene polymerization studies by selected metal derivatives are discussed in Chapter 5. Chapter 6 provides a general conclusion. Appendices are found in the second volume.

### 1.0. Introduction

A major goal of our research was to develop new preorganized polydentate ligands designed to hold more than one metal atom in proximity. We intended to create a well-defined surface-like platform on a discrete polydentate molecule to serve as a model of heterogeneous polymetallic catalyst systems. The re-creation of surface phenomena on a well-defined species will facilitate otherwise difficult mechanistic studies of such heterogeneous systems. We focused on potentially bimetallic or polymetallic catalytic systems such as the supported Ziegler-Natta catalysts (more details will be presented in Chapter 2).

Phenoxide-based preorganized ligand systems were chosen as our main target because of their affinity to early transition metals, in relation to classic Ziegler-Natta catalysts. A widely known example of a preorganized aryloxy-ligand type is the calixarene series, ${ }^{1}$ in which four or more aryloxy rings are conjoined by methylene bridges (Figure 1.1-a). This cyclic ligand system and related derivatives have been investigated in various contexts, including coordination chemistry, host-guest chemistry and supramolecular chemistry.

(b)

Figure 1.1. (a) para-tert-Butylcalix[4]arene. (b) Tetrakis(2-hydroxyphenyl)ethene 2.

As a new type of preorganized aryloxide ligands, tetrakis(2hydroxyphenyl)ethene 2 (Figure 1.1-b) ${ }^{2}$ was developed by Udo Verkerk in our group. Many tetraphenylethene compounds are known, ${ }^{3}$ but very few with a heteroatom donor at the 2-position of all the phenyl rings have been reported. The only example with heteroatoms at all 2-positions was prepared by von Itter et al., in which the low-yield oxidative coupling of the crown ether-macrocyclic hydrazone was reported (Scheme 1.1). ${ }^{4}$ No other heteroatom analogues have been prepared.

Scheme 1.1. Oxidative coupling of diarylhydrazone with a heteroatom donor at every ortho-position by von Itter.

Verkerk established an efficient synthetic route for tetrakis(2hydroxyphenyl)ethene 2, as described in Scheme 1.2. The yield of the key oxidative coupling of the hydrazone (step c) was greatly improved to 80 to $87 \%$ by the use of an acid catalyst. ${ }^{5}$ A mechanistic rationale for the coupling reaction is shown in Scheme 1.3.

Scheme 1.2. Synthesis of tetrakis(2-hydroxyphenyl)ethene 2. Conditions: a. i) $\mathrm{BuLi}, \mathrm{TMEDA}, \mathrm{Et}_{2} \mathrm{O},-65^{\circ} \mathrm{C}$ to r.t., ii) $\left.\mathrm{Me}_{2} \mathrm{NC}(\mathrm{O}) \mathrm{Cl}, \mathrm{iii}\right) \mathrm{H}_{2} \mathrm{O}, \mathrm{HCl}, 73 \%$; b. $\mathrm{H}_{2} \mathrm{NNH}_{2}{ }^{\bullet} \mathrm{H}_{2} \mathrm{O}, n$-BuOH, reflux, $16 \mathrm{~h}, 92 \%$; c. i) $\left.\mathrm{NiO}_{2}, \mathrm{CH}_{3} \mathrm{CN}, 0^{\circ} \mathrm{C}, 1 \mathrm{~h}, \mathrm{ii}\right)$ filtration, then iii) cat. $\mathrm{TsOH}, 80 \%$; d. $\mathrm{BBr}_{3}, \mathrm{CH}_{2} \mathrm{Cl}_{2},-65^{\circ} \mathrm{C}$ to r.t., $16 \mathrm{~h}, 90 \%$.

1

Scheme 1.3. Acid-catalyzed coupling of the diazo compound.

For some metals, ligand 2 shows coordination patterns similar to those of the calix[4]arene ligand. In the titanium(IV) complexes, for example, the para-tertbutylcalix[4]arene exhibits the coordination pattern drawn in Figure 1.2-a. ${ }^{6}$ The sandwich-like dimeric structure, in which the metals are buried in the oxygen coordination sites, is commonly observed with most other oxygen-bound metal complexes reported for para-tert-butylcalix[4]arene. ${ }^{\text {la }}$ The para-tert-butylated analog of 2, prepared analogously to parent ligand $2,{ }^{7}$ gave a titanium complex of a similar structure, shown in Figure 1.2-b. ${ }^{2 a}$ The difference is that there are extra $\mu$-oxygen bridges between two Ti atoms in the latter complex, making the Ti atoms pentacoordinate.

Figure 1.2. Titanium complexes reported for (a) para-tert-butylcalix[4]arene and (b) tetrakis(5-tert-butyl-2-hydroxyphenyl)ethene.

The aluminum complexes of para-tert-butylcalix[4]arene and tetrakis(2hydroxyphenyl)ethene 2 also appear to be similar in some respects. Ligand 2 was reported to give an 8 -membered aluminum-oxygen crown complex upon addition of excess $\mathrm{R}_{3} \mathrm{Al}\left(\mathrm{R}=\mathrm{Et}\right.$ or Me ) or $\mathrm{Et}_{2} \mathrm{AlCl}$, as shown in Figure 1.3-b. ${ }^{2 \mathrm{a}}$ Meanwhile, the adduct of excess $\mathrm{Me}_{3} \mathrm{Al}$ to para-tert-butylcalix[4]arene was reported by Atwood et al. as [ [(ligand $\left.-4 H) \mathrm{Al}_{4} \mathrm{Me}_{8}\right\}_{2}$ ]. ${ }^{8}$ This report, however, does not say how the researchers found it dimeric nor provide any details about structural information. At least, the formula is the same as that of the ligand 2 case.

The adduct of $<1$ equivalent of $\left[\mathrm{H}_{3} \mathrm{Al}\left(\mathrm{NMe}_{3}\right)\right]_{2}$ is reported by Atwood et al. as the sandwich-type structure shown in Figure 1.3-a. ${ }^{8}$ The similar dimeric structure was also found for the ligand 2 case, when the above-mentioned crown complex (Figure 1.3-b) was dissolved in a coordinating solvent such as THF or acetonitrile. These coordinating solvents apparently deprive trialkyl aluminum molecules from the complex to force the ligand system to "collapse" to the aluminum-deficient sandwich structure shown in Figure 1.3-c. The core structure is remarkably similar to that of the calixarene case (Figure 1.3-a).

The "collapsed" dimeric structure of the metal complexes of the calix[4]arene and ligand 2 shows the limitation of the system as a surface-mimic platform. The "surface-
side" is completely covered with another ligand molecule, and the metal atoms are buried in aryloxy donors in the complex. The ligand 2, however, still shows a promising surfacelike structure in the crown complex, in which four aluminum metals are kept in proximity.

(a)

(b)

(c)

Figure 1.3. Aluminum complexes reported for (a) para-tert-butylcalix[4]arene and (b) tetrakis(2-hydroxyphenyl)ethene.

The ligand 2 has a structural advantage over the calixarene system in serving as a more efficient surface-like platform: the position ortho to the hydroxy group is available for further modifications. Introduction of a substituent with steric bulk at the ortho position would reduce the possibility of the dead-end sandwich structure formation or other random aggregation.

Another benefit from ortho-substituent introduction would be an improvement in the solubility of the compound. The poor solubility of ligand 2 itself and the metal derivatives in many common solvents have made analyzing and/or purifying the products difficult. Having no steric protection around the aryloxide groups or coordination sites may increase the intermolecular interactions, leading to aggregation of the complexes or the ligand itself.

This chapter will discuss various modifications of the parent tetraarylethene-based ligand 2. The first theme of ligand modification is the introduction of ortho-substituents. The successful Claisen rearrangement route to introduce propyl group at the ortho
position will be described in detail. Other miscellaneous attempts, including bromination, lithiation and organobismuth-mediated phenylation, will also be described.

Partial protection of the tetrahydroxy ligand to give trihydroxy, dihydroxy, and monohydroxy ligands is another important theme of ligand modification. Adjusting the number of aryloxy and ethereal donors in the ligand allows the ligand framework to fit different metal or metal-containing groups with various oxidation numbers and available coordination sites.

Regioselective alkylation reactions of hydroxy groups in the calix[4]arene case have been established, from monoalkylation to selective dialkylation. Reaction conditions such as the base and the stoichiometry of reagents were carefully chosen to gain the desired selectivity. However, preliminary studies of selective protection of 2 or selective deprotection of the tetramethylether 1 by Verkerk were unsuccessful. ${ }^{2 a, 9}$ As an alternative pathway to trans or cis dialkylation products (3E and 3Z, Section 1.1.2, page 13), a convergent synthesis starting from an unsymmetrical ketone was established and the details will be described in this chapter. Related attempts at selective desymmetrization included the oxidative-regioselective protection of parent ligand 2. Mild oxidation of 2 resulted in an interesting fused-ring product 13 (Section 1.1.2-ii, page 17): the characterization of this compound as well as the attempts to utilize it for regioselective alkylation of $\mathbf{2}$ will be described.

Although not successful, some attempts to introduce heteroatom donors other than oxygen were made as the third theme of ligand modification (Section 1.1.3, page 22). Introduction of other heteroatoms on the tetraarylethene framework would broaden the range of usable metal species. Several failed attempts, including palladium-catalyzed amination of the triflate and catalytic phosphination, will be briefly described.

In the last part of this chapter, the bidentate aryloxy ligand 2,7-bis(1,1-dimethylethyl)-9H-fluorene-1,8-diol 4 (Section 1.2, page 23) will be discussed as a rigid bidentate platform for preorganizing bimetallic sites. The synthesis of ligand 4 was originally reported by Wuest et al. ${ }^{10}$ as a platform for "bidentate Lewis acids" upon coordination to $\mathrm{Al}(\mathrm{III})$ or $\mathrm{Ti}(\mathrm{IV})$ atoms. ${ }^{10,11} \mathrm{We}$ attempted an alternative synthetic route to improve the synthetic efficiency of this ligand, but these attempts did not succeed. The alternate but not necessarily improved synthetic route and the problems encountered will be addressed.

### 1.1. Modification of Tetrakis(2-hydroxyphenyl)ethene Framework

Accomplished or attempted modifications of the parent tetrakis(2hydroxyphenyl)ethene ligand 2 are discussed in the following categories: (1) orthosubstituent introduction, (2) partial protection/deprotection of hydroxy groups, and (3) attempts to introduce other donor heteroatoms.

### 1.1.1. Ortho-Substituent Introduction

Because the same modification is required four times at all the four aryl rings in the ligand 2, the modification reaction must be very clean and efficient. If inefficiency or the effect of side-reaction accumulates four times for a whole molecule, the yield of a desired product can be significantly reduced. The Claisen rearrangement route, the most successful ortho-alkylation route, will be described in the following section. A description of related attempts to modify the ortho-position will follow.
i) Claisen Rearrangement Route. The Claisen rearrangement of the allyloxy ether 5 followed by hydrogenation produced the tetrakis-ortho-propylated ligand 7 successfully (Scheme 1.4). All steps showed good to excellent yield with small and large scales.

The first acetylation step (step a) was clean and quantitative. A pure product was obtained by simple crystallizations without pre-purification by flash chromatography. The small scale reaction (up to 0.1 g ) was completed overnight, but reactions of larger than a gram scale required as long as three days for completion, probably due to the heterogeneous nature of the reaction (especially the base, $\mathrm{K}_{2} \mathrm{CO}_{3}$, was scarcely dissolved in boiling acetone). The next Claisen rearrangement (step b) was not sensitive to the scale-up either, but was accompanied by more yellow-oily impurities. The yield of $80 \%$ was obtained from crystallization only, but the residue, still containing a considerable amount of the right product, would have required flash column chromatography treatment to further obtain pure substance. At the last step (c), a high pressure of hydrogen was important to bring the reaction to completion. Atmospheric pressure of hydrogen saturated only 40 to $50 \%$ of allyl groups after being applied overnight.

2

5

Scheme 1.4. Ortho-propylation of tetrakis(2-hydroxyphenyl)ethene. Conditions: a. $\mathrm{CH}_{2}=\mathrm{CHCH}_{2} \mathrm{Br}, \mathrm{K}_{2} \mathrm{CO}_{3}$, acetone, reflux, 3 days, $90 \%$; b. mesitylene, $200^{\circ} \mathrm{C}$, $16 \mathrm{~h}, 80 \%$; c. $\mathrm{H}_{2}(600 \mathrm{psig})$, cat. $10 \% \mathrm{Pd}-\mathrm{C}, \mathrm{MeOH}$, r.t., $16 \mathrm{~h} ; 74 \%$.

The solubility of ligand 7 in organic solvents was much better than that of parent ligand 2. For example, 7 was readily soluble in hexane at room temperature, whereas 2 was mostly insoluble or only sparingly soluble in hexane, toluene or diethyl ether.

The 'H NMR signals of 7 were all sharp, and only one kind of aromatic ring was observed at room temperature, indicating that the rotation of each ring was not hindered. No low temperature NMR spectroscopy was performed on this system to compare the rotation barrier with parent ligand 2 . The rotation of aryl rings was also found to be free for the precursors 5 and 6 at room temperature in $\mathrm{CDCl}_{3}$ solution.

Interestingly, the ${ }^{1} \mathrm{H}$ NMR spectra of the propylated ligand 7 in various solvents $\left(\mathrm{CDCl}_{3}, \mathrm{C}_{6} \mathrm{D}_{6}\right.$ and THF- $\mathrm{d}_{8}$ ) all showed 3 to 3.5 equivalents of OH group relatively downfield ( $5.74,5.80$ and 7.53 ppm , respectively), and the remaining 1 to 0.5 equivalents were usually found mixed with the $\mathrm{H}_{2} \mathrm{O} / \mathrm{HDO}$ signal at more upfield position ( 3.51 ppm by itself in $\mathrm{CDCl}_{3}, 0.41 \mathrm{ppm}$ with $\mathrm{H}_{2} \mathrm{O}$ in $\mathrm{C}_{6} \mathrm{D}_{6}$, and 2.48 ppm with $\mathrm{H}_{2} \mathrm{O}$ in THF- $\mathrm{d}_{8}$ ). This observation might suggest that a cyclic hydrogen bonding array is held among three out of the four hydroxy groups, and the remaining one hydroxy group is more rapidly exchanging the proton with the water in solution. In contrast, in parent ligand 2, usually two hydroxy groups are found downfield and the other two are found together with the

Chapter 1 I.1.I. page 10
water signal. ${ }^{2}$ This pairwise hydrogen bonding behavior was supported by the X-ray crystallographic structure. ${ }^{2}$ Structural analysis by X-ray crystallography was desired for the propylated ligand 7 or its precursor 6 to confirm the suggested threesome hydrogenbonding array, but growing X-ray-crystallographic quality crystals was not successful despite numerous trials.

The Claisen route was attempted to introduce more substituted allyl groups: crotyl (cis/trans- $\mathrm{CH}_{3} \mathrm{CH}=\mathrm{CHCH}_{2}-$ ) and prenyl $\left[\left(\mathrm{CH}_{3}\right) \mathrm{C}=\mathrm{CHCH}_{2}-\right]$. However, the $O$-crotylation or $O$-prenylation of parent ligand 2 did not proceed to completion under conditions analogous to step a in Scheme 1.4. All reactions gave mixtures of mono-, di-, tri- and a small amount of tetra-substitution. The fact that some amount of the tetra-substituted product was formed suggests that a complete reaction would still be possible under proper conditions, but no further attempts were made.

Branch-introduction at the allylic/benzylic position of the allyl branch in the ortho-allylated complex 6 (Scheme 1.5) was considered a good alternative to the abovementioned attempts to introduce a more branched allylic group. The strategy was to protect the hydroxy groups in 6 first, then lithiate the allylic/benzylic position, followed by quenching with an alkyl halide such as $\mathrm{CH}_{3} \mathrm{I}$ (Scheme 1.5).

The first methylation of 6 was successful: the product 24 was characterized by ${ }^{\prime} \mathrm{H}$ NMR spectroscopy, HRMS and TLC. However, in attempts at crystallization, this product decomposed back to the starting material 6 over several days in a slurry-solution. Why this decomposition happened is unclear, but having four methoxy groups with allyl groups next to them was probably too sterically demanding. Because the crystallization was being tried for the crude product without flash chromatography or other methods to remove the base completely, the demethylation may have been catalyzed by the base left in the crude product.

This observation suggests that introduction of alkyl branches at the allylic/benzylic position may be sterically too demanding in general. One small branch per allyl group may be possible, but this would lead to a mixture of many stereoisomers because the allylic/benzylic positions are diastereotopic. (The steric demand, however, may lead to diastereoselective branch formation.) Introduction of two alkyl branches at each site would solve the stereoisomer problem, but our results suggest that such compounds would be too crowded to form. No further attempts related to this approach were made.

Scheme 1.5. Unaccomplished attempt at branch-introduction at the allylic/benzylic position of 6 due to instability of the methylated complex 24.

Other functionalizations may be possible at the double bond of the allyl branch in the 3-allylated ligand 6, but the susceptibility of the parent system to unwanted side reactions must be taken into consideration. Oxidizing conditions cannot be used, because the conjugated phenol system will likely be affected (see Section 1.1.2-ii). Mild electrophilic addition conditions (in which highly substituted alkenes are not affected) may be a good choice, although this possibility was not pursued.
ii) Other Ortho-Functionalizations Attempts. The major problem in functionalizing the ortho-positions of parent ligand 2 was the prospect of obtaining ortho/para mixtures of products. The para-positions were often as susceptible as the ortho-positions under many electrophilic functionalization conditions, even under those known to have selectivity for the ortho-positions.

Chapter 1 1.I.I. page 12

For example, under ortho-bromination conditions, ${ }^{12}$ parent ligand 2 gave partly para-brominated mixtures. The para-position has to be blocked beforehand for clean ortho-bromination. Verkerk succeeded in clean ortho-bromination using the parablocked (para-tert-butylated) analogs of 1 and 2, using standard conditions. ${ }^{22}$ Perbromination or octabromination of 1 or 2 at all the ortho- and para-positions were also tried by using bromination reagents of various kinds in excess, but these conditions usually resulted in mixtures of incomplete bromination products.

The ortho-directing photo-Fries rearrangement conditions reported by Garcia et al. ${ }^{13}$ looked promising to apply to the tetraacetate of $2(=2-O A c)$ for introducing acetyl group at the ortho-positions. While tetrakis(2-acetoxyphenyl)ethene 2-OAc was prepared quantitatively from parent ligand 2 by standard condition (acetic anhydride and pyridine), the rearrangement reaction resulted in a complicated mixture.

Alkoxy group-directed ortho-litiation conditions, such as the one used for simple anisole (Scheme 1.2, step a), were not successful for conversion of the tetramethoxy ligand 1. The poor solubility of the starting material, as well as the partially lithiated species, may have been a disadvantage for such reactions.

Some organobismuth reagents, such as $\mathrm{Ph}_{5} \mathbf{B i}$, are known to ortho-phenylate the sodium salts of phenols. ${ }^{14}$ However, when used for the phenylation of parent ligand 2, aryl-ring oxidation seems to have accompanied the reaction. The product mixture showed the HRMS signals (EI) of $[2-2 \mathrm{H}],\left[(2-2 \mathrm{H})+\mathrm{C}_{6} \mathrm{H}_{4}\right]$ and $\left[(2-2 \mathrm{H})+2\left(\mathrm{C}_{6} \mathrm{H}_{4}\right)\right]$, in which the core $[2-2 H]$ is considered most likely to be the fused ring product 13 , the DDQoxidation product of 2 (vide infra). The last two masses are apparently of partially phenylated species of such oxidized product.

### 1.1.2. Partial Protection/Deprotection of Hydroxy Groups

As mentioned in the Introduction, preliminary attempts at selective partial etherification of parent ligand 2 or selective deprotection of the tetramethoxy ligand 1 were not successful. The synthesis of $E$ - and $Z$-dialkylated derivatives of 2 ( 3 E and 3 Z ) was, however, accomplished by differentiating the alkoxy groups at the ketone stage.
i) Convergent Synthesis of 3E/3Z. The alkoxy group differentiation of the starting bis(2-methoxyphenyl)methanone was performed in two steps: mono-deprotection to produce the ketone 8 , then benzylation of the freed hydroxy group to give the nonsymmetrical (2-benzyloxyphenyl)(2-methoxyphenyl)methanone 9 (Scheme 1.6).

Scheme 1.6. Synthesis of 3 E and 3 Z . Conditions: a. i) $\mathrm{BCl}_{3}$ /heptane, $\mathrm{CH}_{2} \mathrm{Cl}_{2},-65$ ${ }^{\circ} \mathrm{C}$ to r.t., 75 min , ii) $\mathrm{NaHCO}_{3}, \mathrm{H}_{2} \mathrm{O}, 99 \%$; b. $\mathrm{BnBr}, \mathrm{K}_{2} \mathrm{CO}_{3}$, DMSO, r.t., overnight, $97 \%$; c. $\mathrm{H}_{2} \mathrm{NNH}_{2} \cdot \mathrm{H}_{2} \mathrm{O}, n-\mathrm{BuOH}$, reflux, overnight, $100 \%$; d. i) $\mathrm{NiO}_{2}, \mathrm{CH}_{3} \mathrm{CN}, 0$ ${ }^{\circ} \mathrm{C}, 40 \mathrm{~min}$, ii) filtration, iii) cat. TsOH, $88.5 \%$; e. $\mathrm{H}_{2}(400 \mathrm{psig})$, cat. $10 \% \mathrm{Pd}-\mathrm{C}$, EtOAc-MeOH, r.t., $17 \mathrm{~h},>70 \%$.

The standard coupling procedure of 9 produced a mixture of $E$ - and Z-bis(2-benzyloxyphenyl)-bis(2-methoxyphenyl)ethene 11 . The $E$ - and $Z$-isomers were neither separable nor distinguishable spectroscopically or by TLC at this stage. The coupling step (d) required careful attention: the first ' $\mathrm{NiO}_{2}$ ' oxidation step should be as short as possible, because the benzyl group is apparently susceptible to ' $\mathrm{NiO}_{2}$.' A longer period of exposure to ' $\mathrm{NiO}_{2}{ }^{\prime}$ produced an increased amount of the byproduct Y (Scheme 1.7). The structure of $Y$ is tentatively assigned based on the ${ }^{1} H$ NMR spectroscopy and HRMS. The proposed mechanism of the formation of $Y$ is given in Scheme 1.7. To minimize this side-reaction, the reaction must be carefully monitored by TLC, and as soon as all the starting material has been consumed, the next step (filtration to remove ' $\mathrm{NiO}_{2}$ ') must be promptly performed.

10

Scheme 1.7. Proposed mechanism of the formation of the byproduct $\mathbf{Y}$.

Extra care must also be taken during the work-up stage. When the acid-catalyzed coupling is complete, the catalytic amount of TsOH must be neutralized by adding KOH before removal of the solvent acetonitrile by rotary evaporation. When the acid was left in solution, the rotary evaporation of the mixture resulted in the formation of a significant amount of byproducts. These byproducts (at least two species) were not identified, but showed Rf values and spot colors TLC (UV visualization) similar to those of the desired product.

After de-benzylation by hydrogenolysis, a mixture of the deprotected $E$ - and $Z$ isomers 3 E and 3 Z was obtained. Finding a suitable medium for this hydrogenolysis step was not simple: after trying several solvents and combination of solvents, a mixture of ethyl acetate and methanol at the ratio of $1: 3$ to $1: 4$ was found to be suitable. The reason why this particular system worked is not clear, but the reaction might have been sensitive to the solubility of the starting material 11.

The ratio of 3 E and 3 Z in the product mixture varied in different runs, from $3 / 1$ to $7 / 1$, but 3 E was always the major isomer. The $E$-isomer was probably favored because the large benzyl groups prefer to avoid each other during the coupling step. This finding suggests that more diastereoselective coupling might be attained using larger protecting groups. However, since both alkenes were desired for evaluation of the coordination
ability of the tetraarylethene-based ligand system, no greater control over this coupling was investigated.

The mixture of 3 E and 3 Z was separated by careful flash chromatography or selective crystallization. The visibly different crystal morphology of these isomers helped to distinguish one from the other (each of the crystal portions was final-checked by TLC and/or 'H NMR spectroscopy). Their tendency to adsorb colored contaminants was also different: a trace of blue "Sharpie" pen ink, which was accidentally introduced into the solution, was preferably adsorbed on 3E upon crystallization, while a yellowish organic impurity present in the mixture tended to be adsorbed selectively onto $3 Z$. The stereochemistry of 3E and 3Z was determined by X-ray crystallography of the Z-isomer (see Appendix A-1 for details).

An attempt was made to obtain a single coupling product of known stereochemistry. The coupling of the hydrazone corresponding to the bridging ketone 12 (Scheme 1.8) was expected to produce the Z-isomer exclusively. However, the desired dihydrazone was not produced from 12 under standard conditions, using excess hydrazine monohydrate (ca. 100 equivalents). This reaction resulted in a complicated mixture in which at least 15 to 20 kinds of methoxy signals were found in the ${ }^{1} H$ NMR spectrum. Attempted intramolecular McMurry coupling of 12 also gave a complex mixture.

Scheme 1.8. An attempt to obtain a bridged dihydrazone for intramolecular coupling. Conditions: a. $m-\mathrm{C}_{6} \mathrm{H}_{4}\left(\mathrm{CH}_{2} \mathrm{Br}\right)_{2}, \mathrm{~K}_{2} \mathrm{CO}_{3}$, DMSO, r.t., overnight, $85 \%$; b. $\mathrm{H}_{2} \mathbf{N N H}_{2} \cdot \mathrm{H}_{2} \mathrm{O}$ (ca. 100 equiv), $n$ - BuOH , reflux, overnight.
ii) Oxidation Strategy. One attempted strategy for regioselective partial protection of the hydroxy groups of parent ligand 2 was oxidation with a mild oxidant such as DDQ. It was expected that parent ligand 2, technically a conjugated diphenol, would be oxidized to a conjugated quinone structure (Scheme 1.9). The protection of the remaining two hydroxy groups followed by back-reduction to the tetraarylethene state would give cis- or trans-dialkylated species.

The oxidation of 2 with DDQ, however, did not give a conjugated quinone, but instead gave the interesting fused-ring product 13 (Scheme 1.10). The structure of 13 was characterized by X-ray crystallography (see Appendix A-2). The skeleton of 6-, 5-, 5-, and 6-membered rings has the empirical name of cis-cumarocumaron. The official name given to 13 is cis-4b,9b-dihydro-4b,9b-bis(2-hydroxyphenyl)benzofuro(3,2-b)benzofuran, based on the nomenclature of a very similar compound. ${ }^{15}$

Scheme 1.10. DDQ oxidation of 2 to 13.

The conjugated quinone (as drawn in Scheme 1.9) may still be an intermediate in the formation of 13. The double nucleophilic cyclization of such a conjugated quinone would exclusively produce the cis-cumarocumaron framework over trans, as shown in Scheme 1.11, because the starting conjugated quinone would not be coplanar, but rather twisted at the central C - C bond, due to the steric hindrance.

Scheme 1.11. Proposed mechanism of the formation of 13.

The double cyclization of the possible conjugated quinone occurs in the case of the starting compound 2 because its hydroxy groups are at the 2-positions. A noncyclized conjugated quinone would form if the hydroxy groups were at the 4-positions. Unlike the 2 -hydroxy ligand 2, the 4 -hydroxy version (= tetrakis(4hydroxyphenyl)ethene) has been long known, with the oldest record being found in Behr's report in 1872. ${ }^{16}$ This article also describes the oxidation reaction of tetrakis(4hydroxyphenyl)ethene by $\mathrm{FeCl}_{3}$; the oxidation product had a formula of $\mathrm{C}_{26} \mathrm{H}_{18} \mathrm{O}_{4}$, two H atoms less than the starting material. Although no structural information was available at that time, the author concluded that a quinohydrone-type compound was produced, based on the color of the oxidation product (it was green) and analogies to the color changes of quinohydrone-based dyes. These descriptions strongly suggest that they produced the conjugated quinone as drawn in Figure 1.4.

Figure 1.4. Suggested structure of the oxidation product of tetrakis(4-hydroxyphenyl)ethene.

Similar cyclization upon oxidation was observed with calixarenes. Mild oxidation of para-tert-butylcalix[4]arene, for example, resulted in the formation of the spirodienone from cyclization of each set of two neighboring rings (Figure 1.5). ${ }^{17}$

Figure 1.5. Oxidation product of para-tert-butylcalix[4]arene.

After protection of the hydroxy groups in the cumarocumaron 13, the backreduction to the tetraarylethene state was attempted. The evaluated conditions are listed in Scheme 1.12. Initially, magnesium anthracenide salt was used as a mild reducing agent, but no reaction occurred (eq. a). Use of Na or $\mathrm{Na}-\mathrm{K}$ alloy to reduce a substituted cumarocumaron to the corresponding ethene was then evaluated in various conditions, including those reported by Rigaudy et al. ${ }^{18}$

Scheme 1.12. Protection of 13 and attempts at back-reduction.
Chapter 1 I.I.2. page 19

Starting material 14 remained under milder conditions (eqs. b, c), but the formation of both $\mathbf{3 E}$ and $3 Z$ were observed. Prolonged reduction at room temperature (eqs. c, d) gave the uncharacterized compounds 3X and 3Y.

Unknown 3X showed 'H NMR spectroscopic features similar to those of 3E/3Z, except for a highly downfield, slightly broad doublet of doublet (dd) signal at 8.94 ppm . The ratio of unknown $3 Y$ relative to other products was unclear in the ${ }^{1} H$ NMR spectrum due to the overlapping and probably complicated spectrum. The absence of the desired products ( 3 E and 3 Z ) in the last case (eq. d) was confirmed by TLC and ${ }^{1} \mathrm{H}$ NMR spectroscopy (some signals are close to those of $\mathbf{3 E}$ or 3 Z , but there was no complete coincidence).

The HRMS (EI) of the mixture of the last entry (eq. d ), a mixture of $\mathbf{3 X}$ and $\mathbf{3 Y}$, exhibited two major parent signals, corresponding to $\mathrm{C}_{28} \mathrm{H}_{24} \mathrm{O}_{4}$ (identical to $3 \mathrm{E} / 3 \mathrm{Z}$ ) and $\mathrm{C}_{26} \mathrm{H}_{18} \mathrm{O}_{2}\left(\mathrm{C}_{28} \mathrm{H}_{24} \mathrm{O}_{4}-2\left(\mathrm{OCH}_{3}\right\}\right)$. The IR spectrum of the mixture showed an OH band. Assuming that both the formula of $\mathrm{C}_{28} \mathrm{H}_{24} \mathrm{O}_{4}$ and the OH band belong to the unknown compound 3 X , we tentatively assigned its identity as 1,1-(2-hydroxyphenyl)-2,2-(2methoxyphenyl)ethene (Figure 1.6), the third isomer of 3 E and 3 Z .

Figure 1.6. The structure of $\mathbf{3 X}$ ?

The possible mechanistic route to attain this isomer is provided in Scheme 1.13. The methyl migration is depicted as an intramolecular step. Intermolecular methyl migration is not likely because it would produce monomethoxy and trimethoxy species, the mass of which were not observed in the mass spectrometry.

However, even if the proposed structure of 3 X is correct, why this isomer is preferred over the $E$ - and $Z$-isomers 3 E and $3 Z$ is unclear.

3X ?

Scheme 1.13. Proposed route from 14 to 3X.

### 1.1.3. Attempts to Introduce Other Heteroatoms

There are many known palladium-catalyzed or mediated amination ${ }^{19}$ or phosphination ${ }^{20}$ reactions of aryl halides and aryl triflates. The triflate 15 (Figure 1.7) was prepared from 1 by using a standard condition ( $\mathrm{Tf}_{2} \mathrm{O}, \mathrm{Py}$ ) in attempt to replace the triflate groups with amino or phosphino groups. Various catalyst/phosphine/base/amine combinations were tried, including $\mathrm{Pd}(\mathrm{dba})_{2} / \mathrm{DPPF}^{2} / t-\mathrm{BuONa} / t-\mathrm{BuNH}_{2}{ }^{21}$ and $\mathrm{Pd}(\mathrm{dba})_{2} / \mathrm{BINAP} / \mathrm{t}$ - $\mathrm{BuONa} / \mathrm{aniline}^{21}{ }^{21}$ but none of them worked. The problem was not only with the catalyst, because the same catalysts were confirmed to function for simpler aryl triflates such as 1-methyl-3-tert-butyl-4-triflyloxybenzene and 2triflyloxynaphthalene. The amination reactions of the simpler triflates, however, were often incomplete and/or accompanied by a hydrolyzed product. These reactions might not work for the tetrakis-triflate 15 because (1) the solubility of the starting material is very poor, and (2) when a small degree of hydrolysis per each triflate is accumulated four times, the result is a mixture of partially hydrolized, partially aminated, and partially unreacted triflates.

15

E- isomer: 16E
Z-isomer: $16 Z$

17

Figure 1.7. Triflates 15, 16E, 16 Z and 17.

Although tetrakis-trifrate was obtained for parent ligand 2, triflation was not successful for the ortho-propylated ligand 7 under the standard reaction condition. This result was probably because the ligand framework, with propyl groups next to the hydroxy groups, does not readily accommodate four big triflate groups. The triflate 15 already experiences limited rotation freedom of each aryl ring in solution, as observed in

[^0]Chapter I I.1.3. page 22
the broadened ${ }^{\mathbf{~}} \mathrm{H}$ NMR signals, obviously due to the big triflate substituents. The dialkylated ligand systems 3 E and 3 Z , on the other hand, were readily converted to the corresponding triflates 16E and 16Z (16E was only partially characterized by ${ }^{\prime} \mathrm{H}$ NMR spectroscopy, while 16Z was completely characterized). Catalytic amination conditions, however, also did not work for the two bistriflates. Amination also failed for the bistriflate of 2,2'-dihydroxybenzophenone (17).

### 1.2. Synthesis of 2,7-Bis(1,1-dimethylethyl)-9H-fluorene-1,8-diol (4)

As mentioned in the Introduction, Wuest et al. reported the synthesis of the fluorene diol 4. ${ }^{10} \mathrm{We}$ also worked on this compound because it is an excellent system to enforce non-chelating coordination of two metal atoms held in proximity. Although the total efficiency did not improve greatly, the number of the reaction steps was reduced in the route we developed (Scheme 1.14).

Scheme 1.14. Synthesis of 2,7-bis(1,1-dimethylethyl)-9H-fluorene-1,8-diol 4. Conditions: a. 1 equiv. $\left(\mathrm{CH}_{3}\right)_{2} \mathrm{C}=\mathrm{CH}_{2}$, cat. Me Al , benzene, $100{ }^{\circ} \mathrm{C}, 2 \mathrm{~h}$, incomplete conversion, $50 \%$; b. 0.5 equiv. $\left(\mathrm{CH}_{2} \mathrm{O}\right)_{\mathrm{n}}$, xylenes, $173{ }^{\circ} \mathrm{C}, 13.5 \mathrm{~h}$, $77 \%$; c. i) 2 equiv 'AmONa, 4 equiv. $\mathrm{NaH}, 1$ equiv. $\mathrm{Ni}(\mathrm{OAc})_{2}, 2$ equiv. 2,2'bipyridine, THF, benzene, reflux, ii) I equiv. KI, iii) 21, 33\%.

The efficiency of the condensation (step $\mathbf{b}$ ) was slightly better than that in the case of Wuest et al. ( $77 \%$ vs. $56 \%$ ), while the tert-butylation (step a) ${ }^{22}$ was much more efficient and simpler for their procedure ( $50 \%$ vs. $87 \%$ ). We, however, could not reproduce their reaction ( $t-\mathrm{BuBr}, \mathrm{SiO}_{2}, \mathrm{Na}_{2} \mathrm{CO}_{3}, \mathrm{CCl}_{4}$, reflux). It is suspected that the reaction may be sensitive to the quality of the $\mathrm{SiO}_{2}$, although Wuest et al. state that " $\mathrm{SiO}_{2}$ of the type normally employed for flash chromatography could be used directly without special treatment" (see reference 10(a)).

In the aryl-aryl coupling stage (step c), we utilized the nickel-mediated reductive coupling in the presence of unprotected hydroxy groups, ${ }^{23}$ thus eliminating the protection/deprotection steps in Wuest's procedure. However, the yield did not rise any higher than 33\%, which is lower than the net yield of Wuest's protection-couplingdeprotection steps ( $50.5 \%$ overall). One of the major byproducts in our coupling procedure was over-reduced bis[2-hydroxy-3-(1,1-dimethylethyl)phenyl]methane, in which the bromine atoms in the starting material 21 were replaced with hydrogen atoms.

The inefficiency/difficulty of the synthesis and high price of the starting material discouraged us from pursuing this template for further research. However, some of the metal derivatives of this ligand showed promising ability as ethylene polymerization catalysts (see Chapter 5, Section 5.1). Our group is currently working on the alternative ligand system 3,3'-(1,1-dimethylethyl)-2,2'-dihydroxydibenzofuran to continue the polymerization catalyst project. ${ }^{24}$

Triflation was also attempted for the fluorene-diol 4, in hope of replacing the triflate groups with other heteroatom donor groups. However, the standard triflation condition using $\mathrm{Tf}_{2} \mathrm{O}$ and pyridine did not give the desired product 22 quantitatively. The major product was tentatively assigned to a pyridine adduct 23. The 'H NMR and low resolution MS (FAB) data were consistent with the structure of 23 given in Scheme 1.15. Probably one aromatic proton in 22 was replaced by a pyridinyl group, but the position of the pyridine substitution was not confirmed. The mechanism of formation remains obscure. This type of problem may be avoided by the use of hindered pyridine, such as 2,6-di-tert-butyl-4-methylpyridine.

4

22
(22\%)

(56\%)

Scheme 1.15. Triflation products from 4. Triflate 22 and the major byproduct 23, the pyridine adduct.

Nevertheless, the palladium-catalyzed amination was attempted for the isolated bis-triflate 22, using n-propylamine. The major spot in the product TLC represented a non-symmetrical species, which could be either a single unsymmetrical species or a $1: 1$ mixture of two compounds by the ${ }^{1} \mathrm{H}$ NMR spectroscopy, but the identity of this compound was not confirmed. No propyl group from $n$-propylamine, however, was incorporated on the structure.

### 1.3. Conclusion

The syntheses of the modified ligand 7, the ortho-n-propylated derivative of tetrakis(2-hydroxyphenyl)ethene 2, and the dihydroxy diether derivatives $3 \mathrm{E} / 3 \mathrm{Z}$ were established in the ligand modification project. These ligands were studied for their coordination chemistry (Chapters 2 to 4). Some of the metal derivatives from these ligands, along with the fluorene-diol 4, were evaluated for ethene polymerization catalysis (Chapter 5).

### 1.4. Experimental

Instruments and Analysis: Nuclear magnetic resonance (NMR) spectra for ${ }^{1} \mathrm{H}$ and ${ }^{13} \mathrm{C}$ were recorded on Bruker AM-360, AM-400, AM-300, AM-200, Unity 500 and Unity Inova 500. NMR spectra were obtained at $25^{\circ} \mathrm{C}$ unless otherwise noted. Chemical shifts are reported in parts per million (ppm, $\delta$ ) relative to TMS, and coupling constants are reported as $J$ in Hz . The "apparent" coupling constants of, for example, a doublet of doublets that appear as triplets, or broadened signals in which not all couplings are certain, are reported as $J_{\text {obs }}$ or $J$. The assignment of quaternary ( $4^{\circ}$ ) or tertiary ( $3^{\circ}$ ) for aromatic carbons in ${ }^{13} \mathrm{C}$ NMR spectroscopy is either based on APT or relative intensity of the signals on $B B$ analysis. The olefin $C=C$ carbons are tentatively assigned to the smallest $4^{\circ}$ signal in a proper region in most cases. Elemental analyses were performed by the University of Alberta Microanalytical Service Laboratory. Single crystal X-ray diffraction studies were performed at the X-ray Crystallography Laboratory at the University of Alberta Department of Chemistry by Dr. Robert McDonald. Details of the structure determinations are presented in Appendices. Mass spectra were obtained on Kratos MS-50 High Resolution Mass Spectrometer (EI, at 8kV), Micromass VG 7070E (CI, at 6kV), Kratos MS-9 (FAB at 6kV) or Micromass ZabSpec Sector-TOF (ES, at 4 kV ). FTIR spectra were obtained on Nicolet Magna IR 750 or Nicolet 20SX spectrophotometer. UV-Vis spectra were obtained on HP 8450A Diode Array Spectrophotometer.

Reaction Conditions and Supplemental Materials: Unless stated otherwise, all air- or moisture-sensitive manipulations were conducted under a nitrogen atmosphere by using standard Schlenk techniques. Flasks for moisture or air sensitive reactions were dried in the $120{ }^{\circ} \mathrm{C}$ oven overnight before use. Cylindrical Pyrex vessels equipped with Kontes k 826510 Teflon stopcocks are referred to as "reaction bombs." Some reactions and steps were performed in the drybox (Vacuum Atmospheres He-553-2 Dri-lab equipped with a Mo-41-1 inert gas purifier, a CD-882 Dri-Cold Freezer maintained at $-35^{\circ} \mathrm{C}$, and a DK3E Dri-Kool mechanical refrigeration unit). Flash column chromatographic separations were performed on silica gel 60 (230-400 mesh, SiliCycle). TLC (Silica Gel 60 F-254) was visualized by UV light or Morstein reagent. ${ }^{25}$ Celite filtrations were performed by using Celite 545 on a fritted glass funnel under vacuum.

Materials: Unless indicated otherwise, solvents and reagents were purchased from commercial vendors and used as received (sensitive materials were kept and used under a

Chapter 1 1.4. Experimental page 26
proper conditions to maintain quality). The following solvents/liquid reagents were dried and stored as indicated before use: THF, benzene and hexanes were purified by distillation from sodium benzophenone ketyl; toluene was distilled over potassium and degassed; acetonitrile was distilled from $\mathrm{CaH}_{2}$ freshly before use; pyridine was distilled over calcium hydride and stored over $4 \AA$ molecular sieves; $t$ - AmOH was dried over NaH , distilled, and kept in a bomb; and n-propylamine was dried, distilled from $\mathrm{CaH}_{2}$, and stored under $\mathrm{N}_{\mathbf{2}}$ in a bomb. 3-Bromophenol (18) was dried by azeotropic distillation with benzene and degassed before use in the drybox. The solid materials KI and $\mathrm{Ni}(\mathrm{OAc})_{2}$ were dried under reduced pressure by mild heating overnight with vigorous stirring and stored in the drybox. 2,2'-Bipyridine and BINAP were dried under reduced pressure overnight and stored in the drybox. NaH was washed with hexanes to remove the oil, dried, and stored in the drybox. The following complexes were prepared by following published procedures: tetrakis(2-hydroxyphenyl)ethene (2), ${ }^{2}$ 2,2'-dimethoxybenzophenone, ${ }^{2}$ nickel peroxide ( $\mathrm{NiO}_{2}{ }^{\prime}$ ), ${ }^{26}$ and $\mathrm{Pd}(\mathrm{dba})_{2} .{ }^{27}$

## Tetrakis(2-propen-2-yloxyphenyl)ethene (5)

A mixture of tetrakis(2-hydroxyphenyl)ethene (2) ( $11.4 \mathrm{~g}, 0.0286 \mathrm{~mol}$ ), allyl bromide ( $48.0 \mathrm{~mL}, 0.555 \mathrm{~mol}$ ) and $\mathrm{K}_{2} \mathrm{CO}_{3}(61.5 \mathrm{~g}, 0.445 \mathrm{~mol})$ in 300 mL of acetone was stirred under reflux for 2 days in a flask equipped with a $\mathrm{CaCl}_{2}$ tube. Addition of 10 mL more of allyl bromide ( 0.116 mol ) and 2 more days of stirring under reflux brought the reaction to completion, as determined by TLC analysis. The white precipitate, combined with the residue from the filtrate after removal of volatiles under reduced pressure, was washed with water to remove $\mathrm{K}_{2} \mathrm{CO}_{3}$, dissolved in hot $\mathrm{CH}_{2} \mathrm{Cl}_{2}$, filtered, concentrated, and ether was layered carefully on top of the solution. Slow diffusion gave $7.78 \mathrm{~g} \mathrm{(48.8} \mathrm{\%)}$ of the pure crystalline product. The water washings were extracted with EtOAc and $\mathrm{CH}_{2} \mathrm{Cl}_{2}$, and the combined organic extract was dried over $\mathrm{Na}_{2} \mathrm{SO}_{4}$, filtered, and the volatiles were evaporated. Crystallization of the residue gave an additional 2.38 g ( $15.0 \%$ ) of the pure product. From all the mother liquors, another $4.22 \mathrm{~g}(26.5 \%)$ was obtained by repeating crystallization (total yield: $90.3 \%$ ). ' H NMR ( $360 \mathrm{MHz}, \mathrm{CDCl}_{3}$ ): $\delta 7.23(4 \mathrm{H}$, slightly br d, $J=7.5 \mathrm{~Hz}), 6.98(4 \mathrm{H}, \mathrm{ddd}, J=8,7.5,1.7 \mathrm{~Hz}), 6.64(4 \mathrm{H}, \operatorname{ddd}, J=7.5,7.5,1.0 \mathrm{~Hz})$, 6.61 ( 4 H , slightly br d, $J=8 \mathrm{~Hz}$ ), $5.82(4 \mathrm{H}, \mathrm{ddt}, J=17,11,5 \mathrm{~Hz}$ ), $5.28(4 \mathrm{H}, \mathrm{br} \mathrm{d}, J=17$ $\mathrm{Hz}), 5.12(4 \mathrm{H}, \mathrm{br} \mathrm{d}, J=10.5 \mathrm{~Hz}), 4.26(8 \mathrm{H}, \mathrm{br}) .{ }^{13} \mathrm{C}$ NMR ( $75 \mathrm{MHz}, \mathrm{CDCl}_{3}$ APT): $\delta$ $156.3\left(4^{\circ}, \mathrm{C}-0\right), 137.0\left(4^{\circ}\right), 134.3\left(3^{\circ}\right), 132.6\left(4^{\circ}\right), 132.4\left(3^{\circ}\right), 127.3\left(3^{\circ}\right), 119.6\left(3^{\circ}\right), 116.4$ ( $2^{\circ},-\mathrm{O}-\mathrm{CH}_{2}-\mathrm{C}=$ ), $111.9\left(3^{\circ}\right), 69.0\left(2^{\circ}, \mathrm{H}_{2} \mathrm{C}=\mathrm{C}\right)$. Anal. Calcd for $\mathrm{C}_{38} \mathrm{H}_{36} \mathrm{O}_{4}: \mathrm{C}, 81.99 ; \mathrm{H}$, 6.52. Found: C, 81.83; H, 6.35. HRMS (EI) $m / z$ : Calcd for $\mathrm{C}_{38} \mathrm{H}_{36} \mathrm{O}_{4}: 556.26135$. Found: $556.26202(100 \%)$ [ $\left.\mathrm{M}^{+}\right]$.

## Tetrakis(3-propen-2-yl-2-hydroxyphenyl)ethene (6)

A mixture of tetrakis(2-propen-2-yloxyphenyl)ethene (5) ( $9.08 \mathrm{~g}, 0.0163 \mathrm{~mol}$ ) in 35 mL of mesitylene was degassed in a bomb, which was refilled with nitrogen. The closed bomb was heated to $200^{\circ} \mathrm{C}$ for 16 h with stirring. After concentrating the resulting mixture under reduced pressure, a white precipitate was formed, which was separated from the mixture by washing away the yellow oil with hexanes. The white precipitate was recrystallized from ethyl acetate-hexanes to yield 7.32 g (80\%) of the pure product. ${ }^{1} \mathrm{H}$ NMR ( $360 \mathrm{MHz}, \mathrm{CDCl}_{3}$ ): $\delta 7.01(4 \mathrm{H}, \mathrm{dd}, J=7.5,1.5 \mathrm{~Hz}), 6.87(4 \mathrm{H}, \mathrm{dd}, J=7.5,1.5$ $\mathrm{Hz}), 6.70(4 \mathrm{H}, \mathrm{dd}, J=7.5,7.5 \mathrm{~Hz}) 5.99(4 \mathrm{H}, \mathrm{br} \mathrm{s}, \mathrm{OH}), 5.86(4 \mathrm{H}, \mathrm{ddt}, J=17,10,6 \mathrm{~Hz})$, $5.00(4 \mathrm{H}, \mathrm{ddt}, J=10,1.5,1 \mathrm{~Hz}), 4.79(4 \mathrm{H}, \mathrm{ddt}, J=17,1.5,1 \mathrm{~Hz}), 3.28(8 \mathrm{H}$, slightly br d, $J=6 \mathrm{~Hz}$ ). ${ }^{13} \mathrm{C}$ NMR ( $75 \mathrm{MHz}, \mathrm{CDCl}_{3}, \mathrm{APT}$ ): $\delta 150.6\left(4^{\circ}, \mathrm{C}-\mathrm{O}\right), 137.9(\mathrm{C}=\mathrm{C}), 136.2\left(3^{\circ}\right)$, $129.7\left(3^{\circ}\right), 128.7\left(4^{\circ}\right), 128.4\left(3^{\circ}\right), 126.0\left(4^{\circ}\right), 120.6\left(3^{\circ}\right), 116.1\left(2^{\circ}, \mathrm{H}_{2} \mathrm{C}=\mathrm{C}\right), 34.9\left(2^{\circ},-\mathrm{O}-\right.$ $\mathrm{CH}_{2}-\mathrm{C}=$ ). Anal. Calcd for $\mathrm{C}_{38} \mathrm{H}_{36} \mathrm{O}_{4}: \mathrm{C}, 81.99 ; \mathrm{H}, 6.52$. Found: C, 81.90; H, 6.50. HRMS (EI) $m / z$ : Calcd for $\mathrm{C}_{38} \mathrm{H}_{36} \mathrm{O}_{4}$ : 556.26135 . Found:556.26152 (100\%) [ $\left.\mathrm{M}^{+}\right]$.

Tetrakis(3-propyl-2-hydroxyphenyl)ethene (7)

In a steel autoclave, a solution of tetrakis(3-propen-2-yl-2-hydroxyphenyl)ethene (6) ( $2.55 \mathrm{~g}, 4.57 \mathrm{mmol}$ ) in 120 mL of methanol was pressurized with $\mathrm{H}_{2}(600 \mathrm{psig})$ in the presence of $10 \%$ Pd-C ( $0.052 \mathrm{~g}, 0.24 \mathrm{mmol}$ ) for 10 h at room temperature. After filtration through Celite and removal of the volatiles, the residue was passed through a silica gel column (eluent: hexanes $/ E t O A c=2 / 1$ ) to remove the dark-colored impurity. The product-
containing portions were collected and recrystallized from hexanes (hot to sub-zero) to give pure product ( $1.91 \mathrm{~g}, 74 \%$ ). The mother liquor still contained the right product, which was purified by flash column chromatography together with the remnants from other runs (the yield of this portion was not recorded). 'H NMR ( $360 \mathrm{MHz}, \mathrm{CDCl}_{3}$ ): $\delta$ $6.94(4 \mathrm{H}, \mathrm{dd}, J=7.5,1.5 \mathrm{~Hz}), 6.88(4 \mathrm{H}, \mathrm{dd}, J=7.5,1.5 \mathrm{~Hz}), 6.68\left(4 \mathrm{H}, \mathrm{t}, J_{\text {obs }}=7.5 \mathrm{~Hz}\right)$, 5.74 ( $3 \mathrm{H}, \mathrm{br} \mathrm{s}, \mathrm{OH}$ ), $3.51(1 \mathrm{H}, \mathrm{s}, \mathrm{OH}), 2.45(8 \mathrm{H}, \mathrm{t}, J=7.5 \mathrm{~Hz}), 1.44(8 \mathrm{H}$, sextet, $J=7.5$ $\mathrm{Hz}), 0.80(12 \mathrm{H}, \mathrm{t}, J=7.5 \mathrm{~Hz}) .{ }^{1} \mathrm{H}$ NMR ( $360 \mathrm{MHz}, \mathrm{C}_{6} \mathrm{D}_{6}$ ): $\delta 7.06(4 \mathrm{H}, \mathrm{dd}, J=7.5$, $1.5 \mathrm{~Hz}), 6.74(4 \mathrm{H}, \mathrm{dd}, J=7.5,1.5 \mathrm{~Hz}), 6.61\left(4 \mathrm{H}, \mathrm{t}, J_{\text {obs }}=7.5 \mathrm{~Hz}\right), 5.80(\sim 3,5 \mathrm{H}, \mathrm{s}, \mathrm{OH})$, $2.355(8 \mathrm{H}, \mathrm{t}, J=7.5 \mathrm{~Hz}), 1.41\left(8 \mathrm{H}\right.$, sextet, $\left.J_{\text {obs }}=7.5 \mathrm{~Hz}\right), 0.75(12 \mathrm{H}, \mathrm{t}, J=7.5 \mathrm{~Hz}), 0.41$ $\left(~-3.5 \mathrm{H}, \mathrm{s}, \mathrm{OH}+\mathrm{H}_{2} \mathrm{O}\right) .{ }^{1} \mathrm{H}$ NMR ( $360 \mathrm{MHz}, \mathrm{THF}-\mathrm{d}_{8}$ ): $\boldsymbol{\delta} 7.53(3.3 \mathrm{H}, \mathrm{s}, \mathrm{OH}), 6.97(4 \mathrm{H}, \mathrm{dd}$, $J=7.5,1 \mathrm{~Hz}), 6.74(4 \mathrm{H}, \mathrm{dd}, J=7.5,1 \mathrm{~Hz}), 6.51\left(4 \mathrm{H}, \mathrm{t}, J_{\text {obs }}=7.5 \mathrm{~Hz}\right), 2.48(1.7 \mathrm{H}, \mathrm{s}, \mathrm{OH}$ $\left.+\mathrm{H}_{2} \mathrm{O}\right), 2.44(8 \mathrm{H}, \mathrm{t}, J=7.5 \mathrm{~Hz}), 1.44(8 \mathrm{H}$, sextet, $J=7.5 \mathrm{~Hz}), 0.78(12 \mathrm{H}, \mathrm{t}, J=7.5 \mathrm{~Hz})$. ${ }^{13} \mathrm{C}$ NMR ( $125 \mathrm{MHz}, \mathrm{CDCl}_{3}, \mathrm{APT}$ ): $\delta 150.3,138.1$ (C=C), $129.8,129.6,128.2,127.9$, 120.6, 32.2, 22.9, 13.8. HRMS (EI) $m / z$ : Calcd for $\mathrm{C}_{38} \mathrm{H}_{44} \mathrm{O}_{4}$ : 564.32397 . Found: $564.32246(100 \%)\left[\mathrm{M}^{+}\right]$. Anal. Calcd for $\mathrm{C}_{38} \mathrm{H}_{44} \mathrm{O}_{4}: \mathrm{C}, 80.82 ; \mathrm{H}, 7.85$. Found: C, 80.43; H, 7.71. Tetrakis(3-propen-2-yl-2-methoxyphenyl)ethene (24)

Tetrakis(3-propen-2-yl-2-hydroxyphenyl)ethene (6) ( $0.119 \mathrm{~g}, 0.214 \mathrm{mmol}$ ), $\mathrm{CH}_{3} \mathrm{I}$ ( 0.11 $\mathrm{mL}, 1.8 \mathrm{mmol})$ and $\mathrm{K}_{2} \mathrm{CO}_{3}(0.352 \mathrm{~g}, 2.55 \mathrm{mmol})$ were mixed in DMSO ( 2 mL ) and stirred overnight in a flask equipped with a $\mathrm{CaCl}_{2}$ drying tube and wrapped with aluminum foil to avoid light. The reaction mixture was then diluted with water, extracted with $\mathrm{CH}_{2} \mathrm{Cl}_{2}$, and the combined extracts were washed with water and sat. NaCl and then dried over $\mathrm{Na}_{2} \mathrm{SO}_{4}$. After removal of volatiles, the residue showed the ${ }^{1} \mathrm{H}$ NMR and mass spectroscopy results consistent with the structure of $24(0.131 \mathrm{~g}, 100 \%$, but not pure). Product from a larger scale run ( 2.2857 g of the starting material 6 ) decomposed back to the starting material during recrystallization trials. ${ }^{1} \mathrm{H} \operatorname{NMR}\left(\mathbf{3 6 0} \mathbf{~ M H z}, \mathrm{CDCl}_{3}\right): \delta 7.02$ $(4 \mathrm{H}, \mathrm{br}), 6.95(4 \mathrm{H}, \mathrm{br} \mathrm{d}, J=7 \mathrm{~Hz}), 6.75\left(4 \mathrm{H}, \mathrm{t}, J_{\text {obs }}=7 \mathrm{~Hz}\right), 5.92(4 \mathrm{H}, \mathrm{br} \mathrm{m}$, $\left.\mathrm{H}_{2} \mathrm{C}=\mathrm{CHCH}_{2}-\right), 5.03\left(4 \mathrm{H}\right.$, br d, $\left.J_{\text {obs }}=10 \mathrm{~Hz}, \mathrm{H}_{2} \mathrm{C}=\mathrm{CHCH}_{2}-\right), 4.97\left(4 \mathrm{H}, \mathrm{br} \mathrm{d}, J_{o b s}=18 \mathrm{~Hz}\right.$,
$\mathrm{H}_{2} \mathrm{C}=\mathrm{CHCH}_{2}-$ ), 3.36 ( $12 \mathrm{H}, \mathrm{s}, \mathrm{OMe}$ ), 3.31 ( $8 \mathrm{H}, \mathrm{br}, \mathrm{H}_{2} \mathrm{C}=\mathrm{CHCH}_{2}-$ ). HRMS (EI) $\mathrm{m} / \mathrm{z}$ : Calcd for $\mathrm{C}_{42} \mathrm{H}_{44} \mathrm{O}_{4}: \mathbf{6 1 2 . 3 2 3 9 7}$. Found: $\mathbf{6 1 2 . 3 2 3 5 1 ( 1 0 0 \% )}\left[\mathrm{M}^{+}\right]$.

## Tetrakis(2-acetoxyphenyl)ethene (2-OAc)

2

2-OAc

To a mixture of 1 mL of acetic anhydride and 1 mL of pyridine (distilled from calcium hydride and stored over $4 \AA$ molecular sieves), protected from moisture by a $\mathrm{CaCl}_{2}$ drying tube, was added tetrakis(2-hydroxyphenyl)ethene (2) ( $0.0498 \mathrm{~g}, 0.126 \mathrm{mmol}$ ). The solid completely dissolved after stirring for 5 min . The reaction was followed by TLC. The completion of the reaction was confirmed in 15 min . The mixture was diluted with 10 mL of $\mathrm{CH}_{2} \mathrm{Cl}_{2}$, washed with water ( $5 \mathrm{~mL} \times 2$ ) followed by $1 \mathrm{~N} \mathrm{HCl}(5 \mathrm{~mL}), 5 \% \mathrm{NaHCO}_{3}$, water again ( 5 mL ), and saturated NaCl . The organic solution was dried over anhydrous $\mathrm{Na}_{2} \mathrm{SO}_{4}$, filtered, and the volatiles were removed. Pure product was obtained by recrystallization from acetone. The yield was quantitative. ' $\mathrm{H} \mathbf{N M R}\left(360 \mathrm{MHz}, \mathrm{CDCl}_{3}\right): \delta$ $7.31(4 \mathrm{H}, \mathrm{br}), 7.16(4 \mathrm{H}, \mathrm{td}, J=7.5,1.5 \mathrm{~Hz}), 6.95-6.90(8 \mathrm{H}, \mathrm{br}), 1.98(12 \mathrm{H}, \mathrm{s}, \mathrm{OAc}) .{ }^{13} \mathrm{C}$ NMR ( $75 \mathrm{MHz}, \mathrm{CDCl}_{3}, \mathrm{APT}$ ): $\delta 169.2$ (C=O), 149.2 (ipso) 133.9 (ipso), 133.5, 128.5, 125.1, 122.8, $20.9\left(\mathrm{CH}_{3}\right), \mathrm{C}=\mathrm{C}$ was not observed; Anal. Calcd for $\mathrm{C}_{34} \mathrm{H}_{28} \mathrm{O}_{8}: \mathrm{C}, 72.33 ; \mathrm{H}$, 5.00. Found: C, 72.02; H, 4.97. HRMS (EI) m/z: Calcd for $\mathrm{C}_{34} \mathrm{H}_{28} \mathrm{O}_{8}: 564.17841$. ## 2-Hydroxy-2'-methoxybenzophenone (8)

This reaction was done based on a literature procedure. ${ }^{28}$ To the solution of 2,2'dimethoxybenzophenone ( $6.7 \mathrm{~g}, 0.028 \mathrm{~mol}$ ) in $\mathrm{CH}_{2} \mathrm{Cl}_{2}(95 \mathrm{~mL}$, freshly distilled from $\mathrm{CaH}_{2}$ ) cooled to $-65^{\circ} \mathrm{C}$ under nitrogen atmosphere, was added a solution of $\mathrm{BCl}_{3}$ in
heptane ( $1.0 \mathrm{M}, 52 \mathrm{~mL}, 0.052 \mathrm{~mol}$ ). The mixture was allowed to warm to room temperature over 75 min . The mixture was slowly poured into a stirred sat. $\mathrm{NaHCO}_{3}$ solution cooled in an ice bath. The organic compounds were extracted with $\mathrm{CH}_{2} \mathrm{Cl}_{2}$, and the extract was washed with water, followed by sat. NaCl , and dried over $\mathrm{Na}_{2} \mathrm{SO}_{4}$. After removal of the solvent, the residue was almost pure product, containing $3 \%$ of the starting material ( $6.3 \mathrm{~g}, 99 \%$ ). This material was used as is in the next step. ${ }^{1} \mathrm{H}$ NMR $(360 \mathrm{MHz}$, $\left.\mathrm{CDCl}_{3}\right): \delta 12.18(\sim 0.7 \mathrm{H}, \mathrm{s}, \mathrm{OH}), 7.48(1 \mathrm{H}, \operatorname{ddd}, J=9,7.9,1.9 \mathrm{~Hz}), 7.47(1 \mathrm{H}, \mathrm{ddd}, J=9$, $7.5,1.9 \mathrm{~Hz}), 7.33(1 \mathrm{H}, \mathrm{dd}, J=7.6,1.9 \mathrm{~Hz}), 7.30(1 \mathrm{H}, \mathrm{dd}, J=7.6,1.9 \mathrm{~Hz}), 7.06(1 \mathrm{H}, \mathrm{td}, J$ $=7.5,1 \mathrm{~Hz}), 7.03(1 \mathrm{H}, \mathrm{dd}, J=8.5,1 \mathrm{~Hz}), 7.02(1 \mathrm{H}, \mathrm{d}, \mathrm{br}, J=-8.5 \mathrm{~Hz}), 6.80(1 \mathrm{H}, \mathrm{ddd}, J$ $=\sim 9,7.6,1 \mathrm{~Hz}), 3.78(3 \mathrm{H}, \mathrm{s}, \mathrm{OMe}), 1.56\left(\sim 0.5 \mathrm{H}, \mathrm{s}, \mathrm{OH}+\mathrm{H}_{2} \mathrm{O}\right.$ ). ${ }^{13} \mathrm{C}$ NMR ( 75 MHz , $\left.\mathrm{CDCl}_{3}, \mathrm{APT}\right): ~ \boldsymbol{\delta} 202.2(\mathrm{C}=0), 163.0\left(4^{\circ}\right), 156.6\left(4^{\circ}\right), 136.5,133.8,131.9,128.9,127.9$ ( $4^{\circ}$ ), 125.6, $120.3\left(4^{\circ}\right), 118.7,118.1,111.5,55.7\left(\mathrm{OCH}_{3}\right)$. HRMS (EI) $m / z$ : Calcd for $\mathrm{C}_{14} \mathrm{H}_{12} \mathrm{O}_{3}$ : 228.07864. Found: 228.07876 (35\%) $\left[\mathrm{M}^{+}\right]$, 197.06085 ( $100 \%$ ) $\left[\mathrm{M}^{+}-\mathrm{OCH}_{3}\right]$.

## (2-Benzyloxyphenyl)(2-methoxyphenyl)methanone (9)

A mixture of $8(8.08 \mathrm{~g}, 0.0354 \mathrm{~mol}), \mathrm{K}_{2} \mathrm{CO}_{3}(24.5 \mathrm{~g}, 0.177 \mathrm{~mol})$ and $\mathrm{BnBr}(4.4 \mathrm{~mL}, 0.037$ mol ) in 90 mL of DMSO was stirred at room temperature overnight. The mixture was diluted with diethyl ether and water. The aqueous layer was extracted with fresh diethyl ether, and the combined organic layers were washed with water followed by sat. NaCl and dried over $\mathrm{Na}_{2} \mathrm{SO}_{4}$. After purification by flash chromatography (eluent: $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ / hexanes $=5 / 4 \rightarrow 3 / 2$ ), pure product ( $7.98 \mathrm{~g}, 97 \%$ ) was obtained as clear oil. ${ }^{1} \mathrm{H}$ NMR ( $360 \mathrm{MHz}, \mathrm{CDCl}_{3}$ ): $\delta 7.61(1 \mathrm{H}, \mathrm{dd}, J=8,1.8 \mathrm{~Hz}), 7.57(1 \mathrm{H}, \mathrm{dd}, J=8,2 \mathrm{~Hz}), 7.43(1 \mathrm{H}$, ddd, $J=8.5,7.5,2 \mathrm{~Hz}$ ), 7.39 ( 1 H, ddd, $J=8,7.5,1.8 \mathrm{~Hz}$ ), 7.22~7.18 (3H, overlapping), $7.04(1 \mathrm{H}, \mathrm{td}, J=7.5,1 \mathrm{~Hz}), 6.98 \sim 6.94$ ( 4 H , overlapping), $6.84(1 \mathrm{H}, \mathrm{d}, \mathrm{br}, J=8 \mathrm{~Hz}), 5.45$ ( $2 \mathrm{H}, \mathrm{s}, \mathrm{PhCH}_{2}$ ), $3.60\left(3 \mathrm{H}, \mathrm{s}, \mathrm{CH}_{3}\right) .{ }^{13} \mathrm{C}$ NMR ( $75 \mathrm{MHz}, \mathrm{CDCl}_{3}, \mathrm{APT}$ ): $\delta 195.5(\mathrm{C}=0)$, $158.4\left(4^{\circ}\right), 157.2\left(4^{\circ}\right), 136.4\left(4^{\circ}\right), 132.6,130.9\left(4^{\circ}\right), 130.6\left(4^{\circ}\right), 130.5,130.3,127.5(t w o$ peaks overlapping), 126.7, $120.8,120.4,112.4,111.7,70.1\left(\mathrm{OCH}_{2} \mathrm{Ph}\right), 55.7\left(\mathrm{OCH}_{3}\right)$. HRMS (EI) m/z: Calcd for $\mathrm{C}_{21} \mathrm{H}_{18} \mathrm{O}_{3}: 318.12558$. Found: 318.12606 (22\%) [ $\mathrm{M}^{+}$], $287.10749(16 \%)\left[\mathrm{M}^{+}-\mathrm{OCH}_{3}\right], 227.07093(8 \%)\left[\mathrm{M}^{+}-\mathrm{C}_{7} \mathrm{H}_{7}\right], 91.05485(100 \%)\left[\mathrm{C}_{7} \mathrm{H}_{7}{ }^{+}\right]$.

## (2-Benzyloxyphenyl)(2-methoxyphenyl)methanone hydrazide (10)

A mixture of $9(7.98 \mathrm{~g}, 0.025 \mathrm{~mol})$ and $\mathrm{H}_{2} \mathrm{NNH}_{2}{ }^{\circ} \mathrm{H}_{2} \mathrm{O}(16.0 \mathrm{~mL}, 0.328 \mathrm{~mol})$ in 28 mL of butanol was stirred at reflux temperature overnight. The mixture was diluted with water, and the organic portion was extracted twice with a THF-acetonitrile (1:1). After washing the organic extracts with sat. NaCl and drying over $\mathrm{Na}_{2} \mathrm{SO}_{4}$, the volatiles were removed by rotary evaporator to give a mixture of oil and solid. The solid part increased after being left under reduced pressure (vacuum pump) overnight. The resulting substance weighed more than $>100 \%(8.78 \mathrm{~g})$ and was used as is in the next step. The product gave a complicated ${ }^{1} \mathrm{H}$ NMR spectrum, probably due to the existence of syn/anti isomers. HRMS (EI) $m / z$ : Calcd for $\mathrm{C}_{21} \mathrm{H}_{20} \mathrm{~N}_{2} \mathrm{O}_{2}$ : 332.15247. Found: 332.15233 (16\%) $\left[\mathrm{M}^{+}\right], 316.13307$ (31\%) $\left[\mathrm{M}^{+}-\mathrm{NH}_{2}\right], 301.12286$ (41\%) [ $\left.\mathrm{M}^{+}-\mathrm{N}_{2} \mathrm{H}_{3}\right], 91.05483$ (100\%) $\left[\mathrm{C}_{7} \mathrm{H}_{7}{ }^{+}\right]$.

## E-/Z-Bis(2-benzyloxyphenyl)-bis(2-methoxyphenyl)ethene (11)

10

To a solution of $10(5.60 \mathrm{~g}, 0.0168 \mathrm{~mol})$ in acetonitrile ( 100 mL , freshly distilled from $\mathrm{CaH}_{2}$ ), protected from moisture by a $\mathrm{CaCl}_{2}$ drying tube and cooled to $0^{\circ} \mathrm{C}$, the nickel peroxide ${ } \mathrm{NiO}_{2}{ }^{\text {"26 }}$ (active oxygen atom $2.69 \times 10^{-3} \mathrm{~mol} / \mathrm{g}, 17.3 \mathrm{~g}, 0.0464 \mathrm{~mol}$ ) was added and stirred for 40 min (longer reaction time leads to the increase of formation of the byproduct $\mathbf{Y}$ ). The mixture was filtered quickly through aluminum oxide (activated, basic, activity I), and the flask and the nickel peroxide cake were rinsed with fresh acetonitrile (total of 80 mL ) until the washings were no longer pink-colored. To the deep pink filtrate was added a few drops of a solution of anhydrous $p$-toluenesulfonic acid in
benzene; the color immediately changed to yellow-brown. The catalytic amount of the acid was neutralized by adding a few drops of concentrated aqueous KOH solution to the mixture with stirring (the yellow color became lighter). This treatment was crucial to avoid the formation of unknown byproducts. After removal of volatiles and purification by flash chromatography (silica gel, eluent $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ hexanes $=1 / 3 \rightarrow 1 / 1 \rightarrow 4 / 1$ ), the analytically pure product was obtained ( $4.68 \mathrm{~g}, 88.5 \%$ ). The product is either a single stereoisomer ( $E$ or $Z$ ) or a mixture of the diastereoisomers, but these are not distinguishable spectroscopically.
11 (E/Z). ${ }^{1} \mathrm{H}$ NMR ( $360 \mathrm{MHz}, \mathrm{CDCl}_{3}$ ): $\boldsymbol{\delta} 7.25 \sim 7.15$ ( 6 H , overlapping, br), $7.11(1 \mathrm{H}, \mathrm{d}$, br), 7.03~6.97 ( 2 H , overlapping, br), 6.68~6.59 ( 4 H , overlapping, br), $4.83(2 \mathrm{H}, \mathrm{s}, \mathrm{br}$, $\left.\mathrm{PhCH}_{2}\right), 3.39\left(3 \mathrm{H}, \mathrm{s}, \mathrm{br}, \mathrm{OCH}_{3}\right) .{ }^{13} \mathrm{C}$ NMR ( $75 \mathrm{MHz}, \mathrm{CDCl}_{3}, \mathrm{APT}$ and BB): $\delta 157.4\left(4^{\circ}\right)$, $156.4\left(4^{\circ}\right), 138.0\left(4^{\circ}\right), 137.0\left(4^{\circ}\right), 132.8\left(4^{\circ}\right), 132.4\left(3^{\circ}\right), 132.3\left(3^{\circ}\right), 128.1\left(3^{\circ}\right), 127.34$ $\left(3^{\circ}\right), 127.28\left(3^{\circ}\right), 127.2\left(3^{\circ}\right), 127.1\left(3^{\circ}\right), 119.6\left(3^{\circ}\right), 111.8\left(3^{\circ}\right), 111.0\left(3^{\circ}\right), 69.7\left(\mathrm{PhCH}_{2}\right)$, $55.2\left(\mathrm{CH}_{3}\right)$, one $4^{\circ}$ carbon and one $3^{\circ}$ carbon are missing or overlapping with other peaks in the aromatic region. Anal. Calcd for $\mathrm{C}_{42} \mathrm{H}_{36} \mathrm{O}_{4}: \mathrm{C}, 83.42 ; \mathrm{H}, 6.00$. Found: $\mathrm{C}, 83.24 ; \mathrm{H}$, 6.02. HRMS (EI) $m / z$ : Calcd for $\mathrm{C}_{42} \mathrm{H}_{36} \mathrm{O}_{4}: 604.26135$. Based on this data, the byproduct is tentatively assigned structure $Y$ (see Scheme 1.7).

## E-/Z-Bis(2-hydroxyphenyl)-bis(2-methoxyphenyl)ethene (3E, 3Z)

Due to the limited volume of the reaction apparatus, the reaction was done in two separate runs, and the resulting mixture was combined for purification.

In a steel autoclave, a mixture of 11 and $10 \% \mathrm{Pd}-\mathrm{C}$ in EtOAc and MeOH was pressurized with $\mathrm{H}_{2}$ under 400 psig for 17 h . In the first run were used $2.01 \mathrm{~g}(3.32 \mathrm{mmol})$ of 11 , $0.355 \mathrm{~g}(0.334 \mathrm{mmol})$ of $10 \% \mathrm{Pd}-\mathrm{C}, 40 \mathrm{~mL}$ of EtOAc and 160 mL of MeOH . In the second run were used $2.48 \mathrm{~g}(4.10 \mathrm{mmol}), 0.429 \mathrm{~g}(0.403 \mathrm{mmol}), 50 \mathrm{~mL}$ and 155 mL , respectively. After the hydrogenation was complete, the mixture was filtered through Celite to remove the bulk of the catalyst, and the volatiles were removed. The $E / Z$ mixture (crude ratio shown by ${ }^{1} \mathrm{H}-\mathrm{NMR}$ spectroscopy was $7 / 1$ ) was separated by flash chromatography (hexanes/EtOAc $=20 / 1$, then $10 / 1$ ). After crystallization of each of the $E$-dominant portion and the Z-dominant portion, $1.24 \mathrm{~g}(39 \%)$ of $E$-isomer 3 E and 0.3817 $\mathrm{g}(12 \%)$ of $Z$-isomer $3 Z$ were obtained. The $E / Z$ mixture portion was $17 \%$. By use of crystal seeding, 3 E or $3 Z$ were further crystallized individually from the mixture portion and the mother liquors. The stereochemistry of each isomer was assigned based on the X ray crystallography of $\mathbf{3 Z}$ (see Appendix A-1). The crystals of $\mathbf{3 Z}$ used for X-ray analysis were grown from EtOAc-hexanes by slow diffusion.

## Compound 12

8

12

A mixture of 2-hydroxy-2'-methoxybenzophenone (8) ( $\mathbf{3 . 0 1} \mathrm{g}, 13.2 \mathrm{mmol}$ ), $\mathrm{K}_{2} \mathrm{CO}_{3} \mathbf{( 9 . 1 0}$ $\mathrm{g}, 65.9 \mathrm{mmol}$ ) and $\alpha, \alpha^{\prime}$-dibromo-m-xylene ( $1.88 \mathrm{~g}, 7.11 \mathrm{mmol}$ ) in 30 mL of DMSO was stirred at room temperature overnight. The mixture was then diluted with diethyl ether and water. The aqueous layer was extracted with fresh diethyl ether, and the combined organic layers were washed with water, followed by sat. NaCl , and dried over $\mathrm{Na}_{2} \mathrm{SO}_{4}$. After purification by flash chromatography (eluent: $\mathrm{CH}_{2} \mathrm{Cl}_{2} /$ hexanes $=1 / 0 \rightarrow 39 / 1 \rightarrow$ $29 / 1 \rightarrow 19 / 1$ ), pure product ( $2.96 \mathrm{~g}, 85 \%$ ) was obtained as slightly yellow, clear oil. ${ }^{1} \mathrm{H}$ NMR ( $360 \mathrm{MHz}, \mathrm{CDCl}_{3}$ ): $\delta 7.59(2 \mathrm{H}, \mathrm{dd}, J=7.5,1.8 \mathrm{~Hz}), 7.52(2 \mathrm{H}, \mathrm{dd}, J=7.5,1.8 \mathrm{~Hz}$ ), 7.44 ( 2 H , ddd, $J=8.1,7.5,1.8 \mathrm{~Hz}$ ), 7.33 ( 2 H , ddd, $J=8.1,7.5,1.8 \mathrm{~Hz}$ ), $7.05(2 \mathrm{H}$, ddd, $J$ $=7.1,7.5,0.8 \mathrm{~Hz}), 7.05^{\prime}(1 \mathrm{H}, \mathrm{t}, J=7.5 \mathrm{~Hz}), 6.945(2 \mathrm{H}, \mathrm{dd}, J=8.1 \mathrm{~Hz}$, smaller $J$ could not be determined), $6.94(2 \mathrm{H}$, ddd, $J=7.5,7.5,0.8 \mathrm{~Hz}), 6.80\left(2 \mathrm{H}\right.$, br d, $\left.J_{o b s}=7.5 \mathrm{~Hz}\right)$, $6.79\left(2 \mathrm{H}, \mathrm{br} \mathrm{d}, J_{o b s}=8.1 \mathrm{~Hz}\right), 6.61(1 \mathrm{H}, \mathrm{br} \mathrm{s}), 4.85\left(4 \mathrm{H}, \mathrm{s},-\mathrm{CH}_{2} \mathrm{O}\right), 3.56\left(6 \mathrm{H}, \mathrm{s}, \mathrm{CH}_{3} \mathrm{O}\right)$. ${ }^{13} \mathrm{C}$ NMR ( $75 \mathrm{MHz}, \mathrm{CDCl}_{3}, \mathrm{APT}$ ): $\delta 195.3(\mathrm{C}=0), 158.5\left(4^{\circ}\right), 157.2$ ( $4^{\circ}$ ), 136.4* (4${ }^{\circ}$ ), 132.7, $132.6131 .0\left(4^{\circ}\right), 130.5,130.4,128.6,128.3,126.0,124.9,120.9,120.3,112.4$, 111.7, $70.0\left(\mathbf{C H}_{2}\right), 55.7\left(\mathrm{CH}_{3}\right)$; *Probably two $4^{\circ}$ signals are overlapping. HRMS (EI) $\mathrm{m} / \mathrm{z}$ : Calcd for $\mathrm{C}_{36} \mathrm{H}_{30} \mathrm{O}_{6}$ : 558.20422 . ## Tetrakis(2-trifluoromethanesulfonyoxyphenyl)ethene (15)

2

15

The mixture of 4.30 g ( 0.0108 mol ) of tetrakis(2-hydroxyphenyl)ethene (2) in 24 mL of pyridine was prepared and placed under nitrogen atmosphere. To the mixture cooled to 0 ${ }^{\circ} \mathrm{C}$ was slowly added $1 / 3$ portion of trifluoromethanesulfonic anhydride (total added: 9.0 $\mathrm{mL}, 15.5 \mathrm{~g}, 0.055 \mathrm{~mol}$ ) via syringe. The remaining anhydride was added after letting the initial mixture stir for several minutes. The white solid that formed on the side of the vial was dissolved by immersing the reaction mixture in an ultrasound bath. The dark brown solution was allowed to warm to room temperature, then stirred for 24 h . The mixture was then diluted with 60 mL of water, which was accompanied by the formation of a precipitate. The mixture was extracted with 50 to 100 mL of diethyl ether five times until no product was observed by TLC. The combined ether extracts were washed with 50 mL of water, followed by $10 \% \mathrm{HCl}$, water again, and sat. NaCl . The combined aqueous washings were re-extracted with diethyl ether ( $20 \mathrm{~mL} \times 2$ ). The combined organic layers were dried over $\mathrm{MgSO}_{4}$, filtered, and the solvent was evaporated. The yellow color impurities were removed from the residue by passing through a silica gel packed column
(with eluent: $\mathrm{CCl}_{4} / \mathrm{CH}_{2} \mathrm{Cl}_{2}=2 / 1$ ). The colorless crude product was purified by recrystallization from acetone or acetone-acetonitrile. The yield was quantitative. ${ }^{1} \mathrm{H}$ NMR ( $360 \mathrm{MHz}, \mathrm{CDCl}_{3}$ ): $\delta 7.44(4 \mathrm{H}, \mathrm{br}), 7.30(4 \mathrm{H}, \mathrm{ddd}, \mathrm{J}=9,7.3,1.8 \mathrm{~Hz}), 7.22(4 \mathrm{H}$, br), $6.84(4 \mathrm{H}, \mathrm{br}) .{ }^{13} \mathrm{C}$ NMR ( $125 \mathrm{MHz}, \mathrm{CDCl}_{3}$ ): $\delta 147.9$ (br, $4^{\circ}$ ), 135.4 (br, $3^{\circ}$ ), 134.3 (br, $4^{\circ}$ ), 132.5 ( $\mathrm{br}, 4^{\circ}$ ), 130.3 (sharp, $3^{\circ}$ ), $127.9\left(\mathrm{br}, 3^{\circ}\right), 121.0\left(\mathrm{br}, 3^{\circ}\right), 118.3\left(\mathrm{q}, \mathrm{J}_{\mathrm{c.F}}=443 \mathrm{~Hz}\right.$, $\mathrm{CF}_{3}$ ). Anal. Calcd for $\mathrm{C}_{30} \mathrm{H}_{16} \mathrm{~F}_{12} \mathrm{O}_{12} \mathrm{~S}_{4}$ : C, 38.97; $\mathrm{H}, 1.74 ; \mathrm{S}, 20.76$. ## Z-Bis(2-trifluoromethanesulfonyloxyphenyl)-bis(2-methoxyphenyl)ethene (16Z)

To the solution of Z-bis(2-hydroxyphenyl)-bis(2-methoxyphenyl)ethene (3Z) (0.504 g, $1.19 \times 10^{-3} \mathrm{~mol}$ ) in pyridine ( 2 mL ) in an oven-dried flask, which was cooled to $0^{\circ} \mathrm{C}$ and protected from moisture by a $\mathrm{CaCl}_{2}$ drying tube, was slowly added trifluoromethanesulfonic anhydride ( $1.1 \mathrm{~mL}, 6.71 \times 10^{-3} \mathrm{~mol}$ ). Vigorous reaction with white smoke was observed, and the reaction mixture became reddish immediately. After the addition, more pyridine ( 2 mL ) was added to dilute the mixture and permit continued stirring. The mixture was allowed to warm to room temperature and stirred overnight. The mixture was then diluted with water, extracted with ether until the extract showed no product by TLC analysis, and the combined extracts were washed with 1 N HCl (x 2), water, sat. NaCl , then dried over $\mathrm{Na}_{2} \mathrm{SO}_{4}$. After removal of the volatiles, the residue was crystallized from $\mathrm{CH}_{2} \mathrm{Ci}_{2}$-hexanes to give pure product ( $0.657 \mathrm{~g}, 84 \%$ ). ${ }^{1} \mathrm{H}$ NMR ( 360 MHz, DMSO- $\mathrm{d}_{6}$ ): $\delta$ 7.32-7.27 ( $2 \mathrm{H}+2 \mathrm{H}$, overlapping, br), 7.13-7.03 $(2 \mathrm{H}+2 \mathrm{H}+2 \mathrm{H}$, overlapping, br), $6.98(2 \mathrm{H}, \mathrm{br} \mathrm{d}, J=\sim 7 \mathrm{~Hz}), 6.84\left(2 \mathrm{H}, \mathrm{br} \mathrm{d}, J_{o b s}=8 \mathrm{~Hz}\right), 6.70(2 \mathrm{H}, \mathrm{br} \mathrm{t}$, $J_{o b s}=7.5 \mathrm{~Hz}$ ). ${ }^{13} \mathrm{C}$ NMR ( $125 \mathrm{MHz}, \mathrm{DMSO}-\mathrm{d}_{6}, 100^{\circ} \mathrm{C}$ ): $\delta 156.8,145.7\left(4^{\circ}\right), 135.2\left(4^{\circ}\right)$, $134.1,132.0\left(4^{\circ}\right), 130.6,130.2\left(4^{\circ}\right), 128.8,128.7,126.8,119.35,119.32,117.5(\mathrm{q}, J=$ $319 \mathrm{~Hz}, \mathrm{CF}_{3}$ ), 111.0, $54.5\left(\mathrm{OCH}_{3}\right)$, one $4^{\circ}$ carbon missing. Anal. Calcd for $\mathrm{C}_{30} \mathrm{H}_{22} \mathrm{~F}_{6} \mathrm{O}_{8} \mathrm{~S}_{2}$ : C, 52.33; H, 3.22; S, 9.31. Found: C, 52.16; H, 3.15; S, 9.71. HRMS (EI) m/z: Calcd for

Chapter I 1.4. Experimental page 39
$\mathrm{C}_{30} \mathrm{H}_{22} \mathrm{~F}_{6} \mathrm{O}_{8} \mathrm{~S}_{2}$ : 688.0661 . Found: 688.06529 ( $100 \%$ ) $\left[\mathrm{M}^{+}\right]$, 555.10877 ( $13 \%$ ) [M $\left.\mathrm{SO}_{2} \mathrm{CF}_{3}\right]^{+}, 422.15122$ (29\%) $\left[\mathrm{M}-2\left(\mathrm{SO}_{2} \mathrm{CF}_{3}\right)\right]^{+}$.

## E-Bis(2-trifuoromethanesulfonyloxyphenyl)-bis(2-methoxyphenyl)ethene (16E)

This product was prepared from 3E in the same way as 16 Z was from 3 Z . From 0.0568 g of 3 E ( 0.134 mmol ) with 1 mL of pyridine and $0.11 \mathrm{~mL}(0.67 \mathrm{mmol})$ of trifluoromethanesulfonic anhydride, the crude product 16 E was obtained quantitatively (crude yield: $0.0928 \mathrm{~g}, 101 \%$ ). Crystallization from $\mathrm{CH}_{2} \mathrm{Cl}_{2}$-hexanes gave clear prism crystals. ${ }^{1} \mathrm{H}$ NMR ( $360 \mathrm{MHz}, \mathrm{CDCl}_{3}$ ): $\boldsymbol{\delta} 7.32(2 \mathrm{H}, \mathrm{br} \mathrm{d}, J=6 \sim 7 \mathrm{~Hz}$ ), 7.16-7.02 ( $2 \mathrm{H} \times 5$, overlapping, br), $6.71(2 \mathrm{H}$, br $\mathrm{t}, J=\sim 7 \mathrm{~Hz}), 6.67(2 \mathrm{H}$, br d, $J=8 \sim 8.5 \mathrm{~Hz}), 3.48(6 \mathrm{H}, \mathrm{s}$, OMe ). The structure was tentatively assigned based on the symmetry of the product shown in 'H NMR spectroscopy and comparison with the Z-analogue.

## 2,2'-Dihydroxybenzophenone bistriflate (17)

17

This product was prepared from commercially purchased $2,2^{\prime}$-dihydroxybenzophenone in the same way as 16 Z was from 3 Z . From 1.50 g of $2,2^{\prime}$-dihydroxybenzophenone ( 7.0 $\mathrm{mmol})$ with 6.5 mL of pyridine and $2.7 \mathrm{~mL}(16.5 \mathrm{mmol})$ of trifluoromethanesulfonic anhydride, the crude product 17 was obtained. Flash chromatography did not purify the product completely, as seen in the $>100 \%$ yield ( $3.27 \mathrm{~g}, 113 \%$ ). ${ }^{1} \mathrm{H}$ NMR ( 360 MHz , $\mathrm{CDCl}_{3}$ ): $\delta 7.67\left(2 \mathrm{H}+2 \mathrm{H}\right.$, overlapping, dd and dt), $7.51\left(2 \mathrm{H}, \mathrm{t}, J_{\text {obs }}=8.5 \mathrm{~Hz}\right)$. HRMS (EI) $m / z$ : Calcd for $\mathrm{C}_{15} \mathrm{H}_{18} \mathrm{~F}_{6} \mathrm{O}_{7} \mathrm{~S}_{2}: 477.96157$. Found: 477.96324 ( $100 \%$ ) [ $\left.\mathrm{M}^{+}\right], 329.00438$ (47\%) $\left[\mathrm{M}-\mathrm{OSO}_{2} \mathrm{CF}_{3}\right]^{+}$.

Catalyst preparation: Tris(5-bromophenoxy)aluminum was prepared in the drybox by slowly adding dropwise 3-bromophenol (18) ( $2.75 \mathrm{~g}, 21.7 \mathrm{mmol}$ ) to the solution of $\mathrm{Me}_{3} \mathrm{Al}(\mathbf{0 . 4 9 1} \mathrm{g}, 6.81 \mathrm{mmol})$ in pentane ( 35 mL ) prepared in a 50 mL Schlenk flask. A small amount of toluene was used to rinse the container that contained 18. Gentle reflux was maintained while a weak vacuum was applied on the sidearm of the Schlenk flask to reduce the amount of evolving gas escaping to the box's atmosphere. A white precipitate started to form when about $\mathbf{3 / 4}$ of $\mathbf{1 8}$ had been added. After completion of the addition, the mixture was stirred for 5 more minutes, and then the volatiles were removed in vacuo. The white powder was collected, rinsed with pentane, followed by a small amount of toluene (to remove remaining 18), rinsed again with pentane, and dried in vacuo. The yield was $>95 \%$.
Small scale: Under inert atmosphere, 2-methylpropene was introduced to a coldfinger cooled with dry ice, to condense in a preweighed bomb. The bomb with condensed 2 methylpropene was closed, warmed to room temperature, and reweighed to obtain the mass of 2-methylpropene ( $0.895 \mathrm{~g}, 0.0160 \mathrm{~mol}$ ). In the drybox, 18 ( $2.76 \mathrm{~g}, 0.0160 \mathrm{~mol}$ ) and the catalyst tris(5-bromophenoxy)aluminum ( $0.437 \mathrm{~g}, 8.05 \times 10^{-4} \mathrm{~mol}$ )were weighed based on the mass of 3-methylpropene and mixed in benzene in a second reaction bomb. The second bomb had to be large enough to contain all the reagents. Out of the drybox, 2methylpropene was transferred to the bomb containing 18 by connecting the two bombs under inert atmosphere, isolating the system, cooling the latter bomb to $-60^{\circ} \mathrm{C}$ and opening the valves to both bombs. After the transfer, the bomb was closed, allowed to warm to r.t., then heated in an oil bath (immersed to the neck level for even heating) at $100-110{ }^{\circ} \mathrm{C}$ for longer than 27 h . After the heating period, the bomb was cooled to r.t., opened to the atmosphere, and $10 \% \mathrm{HCl}$ was added to liberate the phenoxides from the catalyst. The organic layer was separated from the aqueous layer, which was further extracted with additional benzene. The combined organic layer was washed with $10 \%$ HCl , followed by water, dried over $\mathrm{MgSO}_{4}$, and filtered. The volatiles were removed from the filtrate in vacuo to give the crude product mixture, in which 18 (unreacted), 19
and 20 (overreacted) were found at the ratio of [6:58:30], according to the ${ }^{1} \mathrm{H}$ NMR spectroscopy.
Large scale: Two separate reactions were performed following the small-scale procedure, and the product mixtures were combined for purification. Reaction (I): 2methylpropene ( $6.24 \mathrm{~g}, 0.111 \mathrm{~mol}$ ), $18(17.1 \mathrm{~g}, 0.0988 \mathrm{~mol})$, the Al catalyst ( $5.24 \mathrm{~g}, 9.65$ $\times 10^{-3} \mathrm{~mol}$ ), and benzene ( 80 mL ) were used. The heating temperature was $170-180^{\circ} \mathrm{C}$ using heating tape instead of oil bath, and the heating period was 40 h . Reaction (II): 2methylpropene ( $9.0 \mathrm{~g}, 0.16 \mathrm{~mol}$ ), $18(27.7 \mathrm{~g}, 0.160 \mathrm{~mol})$, the catalyst $\left(4.36 \mathrm{~g}, 8.03 \times 10^{-3}\right.$ mol), and benzene ( 85 mL ) were used. The heating temperature was $176-178{ }^{\circ} \mathrm{C}$ using an oil bath, and the heating period was 24 h . The product mixture ratio [18:19:20] was [2: $41: 57]$ and [3:46:50], respectively. The separation/purification by careful flash chromatography was performed on the combined product mixtures by using hexanes/EtOAc $=1 / 0 \rightarrow 100 / 1 \rightarrow 50 / 1 \rightarrow 20 / 1 \rightarrow 10 / 1 \rightarrow 2 / 1$. The purest portion of 19 ( $31.1 \mathrm{~g}, 50 \%$ ) still contained up to $5 \%$ of the byproduct 20 . The yield was calculated based on the starting material 18 and the total amount of the phenol contained in the catalyst.

## Bis[5-bromo-3-(1,1-dimethylethyl)-2-hydroxyphenyl]methane (21) ${ }^{30}$

19

21

In a reaction bomb, 3-bromo-5-(1,1-dimethylethyl)phenol (19) ( $11.1 \mathrm{~g}, 0.0484 \mathrm{~mol}$ ) was weighed, and then paraformaldehyde ( $0.725 \mathrm{~g}, 0.0242 \mathrm{~mol}$ ) and xylenes $(5.14 \mathrm{~g}, 0.0484$ mol ) were added. The closed bomb was heated to $173{ }^{\circ} \mathrm{C}$ for 13.5 h . The color turned from almost colorless to yellowish-orange. After removal of the bulk of the volatiles in vacuo, the thick residue was purified by flash chromatography (eluent: hexane/EtOAc = $1 / 0 \rightarrow 500 / 1 \rightarrow 30 / 1$ ). The reasonably pure portion yielded 4.6 g (40\%). Less pure portions provided an additional $4.3 \mathrm{~g}(37 \%)$. These products were recrystallized from hexane prior to use in the next step. The identity of the product was confirmed by ${ }^{1} \mathrm{H}$ NMR spectroscopy and was identical to the data reported by Wuest et al. See reference 10.

## 2,7-Bis(1,1-dimethylethyl)-9H-fluorene-1,8-diol (4)

1) 2 equiv $t$-AmONa

21

2) 1 equiv. KI
3) $21,33 \%$.

4

The procedure of Caubère et al. was adapted. ${ }^{23}$ The following three mixtures were prepared in separate Schlenk flasks in the drybox: (a) Suspension of $\mathrm{NaH}(0.288 \mathrm{~g}$, $0.0120 \mathrm{~mol}), \mathrm{Ni}(\mathrm{OAc})_{2}(0.354 \mathrm{~g}, 2.00 \mathrm{mmol})$ and $2,2^{2}$-bipyridine $(0.625 \mathrm{~g}, 4.00 \mathrm{mmol})$ in THF-benzene ( $5+5 \mathrm{~mL}$ ); (b) THF-benzene ( $1+1 \mathrm{~mL}$ ) to which $t$-AmOH ( $0.44 \mathrm{~mL}, 4.0$ mmol) was added outside of the drybox later; and (c) bis[5-bromo-2-hydroxy-3-(1,1dimethylethyl)phenyl]methane (21) ( $0.471 \mathrm{~g}, 1.00 \mathrm{mmol}$ ) in THF-benzene ( $1.2+1.2$ mL ). The Schlenk flasks were taken out of the drybox and placed under nitrogen atmosphere. Flask (a) was equipped with a condenser and brought to reflux. The color became darker. The contents of flask (b) were then transferred to flask (a); gas evolution was observed. Anhydrous KI ( $0.338 \mathrm{~g}, 2.03 \mathrm{mmol}$ ) was quickly weighed and added to the mixture. After keeping the mixture at reflux for 1.5 h , the contents of flask (c) were added. Vigorous reaction was observed with the color turning to dark greenish purple. The reaction was monitored by TLC. After 13 h , the dark purple mixture was cooled to r.t. A small amount of EtOH was added dropwise to quench excess hydride. The mixture was then acidified with $5 \% \mathrm{HCl}(25 \mathrm{~mL})$; the exothermic reaction was accompanied by a color change to greenish brown and precipitate formation. The mixture was extracted with ether ( $25 \mathrm{~mL} \times 2$ ). The combined extracts were dried over $\mathrm{MgSO}_{4}$. After removal of the solvent, the residue was purified by flash chromatography (eluent: hexanes/EtOAc = $20 / 1$ ). Fairly pure product 4 was obtained ( $0.104 \mathrm{~g}, 33 \%$ ) and identified by spectroscopic comparison to the known compound (see reference 10). This product was further purified by crystallization (toluene-hexane) prior to use in the preparation of metal derivatives. The byproducts included uncoupled, over-reduced product Bis[2-hydroxy-3-(1,1dimethylethyl)phenyl]methane, tentatively assigned by ${ }^{1}$ H NMR spectroscopy and HRMS analysis.

## Chapter 2

## Preface to Chapters 3 and 4:

## Basic Concepts and Strategies for the Coordination Studies of the Tetrakis(2-hydroxyphenyl)ethene-Derived Preorganized

## Ligands

In the following two chapters (Chapters 3 and 4), the synthesis, structure, spectroscopic features, and chemical behavior of metal complexes prepared from the modified tetrakis(2-hydroxyphenyl)ethene-based ligands will be discussed.

Prior to this work, little was known about this new ligand system's ability to coordinate to metal atom(s). After establishing a few successful modification routes of parent ligand 2 as described in Chapter 1, the next goal was to evaluate the coordination behavior of those modified tetraarylethene systems. The effect of ortho-alkylation (as in 7), as well as the effect of partial etheration of hydroxy groups (as in $\mathbf{3 E}$ and $\mathbf{3 Z}$ ) on the coordination behavior, needed to be examined.

Before going into the details and specifics of each metal complex, it is useful to review the basic features of the parent ligand system 2 related to its coordination behavior, and to define some concepts and terms. The first section of this chapter will outline the flexibility, symmetry, ring-tilting tendency and classification of conformations of the tetrakis(2-hydroxyphenyl)ethene-based ligand system, with specific comparisons to the calix[4]arene system.

The latter part of this chapter will describe the concepts and background of the "surface-mimic" study using these ligands. Many of the coordination studies presented in this thesis are related to our attempts to create a well-defined mimic of heterogeneous $\mathrm{MgCl}_{2}$-supported $\mathrm{TiCl}_{4}$ olefin polymerization catalysts. The proposed structure of the catalytic center of such heterogeneous catalysts and phenoxide-based olefin polymerization catalysts will be reviewed, followed by a description of the general
approach taken to obtain a surface-mimic of such systems by using tetrakis(2-hydroxyphenyl)ethene-based ligands.

## 2.A. Flexibility and Symmetry of the Tetrakis(2-hydroxyphenyl)ethene System as a Coordination Platform

2.A.1. Ring Rotation. The rotation dynamic of each aryl ring is one of the unique features of tetrakis(2-hydroxyphenyl)ethene-based ligands. The calixarene system also has rotatary freedom and flexibility, but the nature of the rotation is obviously different. Figure 2.1 shows the rotation axes of tetrakis(2-hydroxyphenyl)ethene (a) and calix[4]arene system (b). The former rotates each ring about the ethene plane by "tilt" rotation, while the latter flexes on an inward/outward manner.

(a)

(b)

Figure 2.1. Rotation axes of (a) tetrakis(2-hydroxyphenyl)ethene 2 and (b) calix[4]arene.
2.A.2. Backbone-Rigidity and Symmetry. The ethene-backbone gives some degree of rigidity to the ligand framework. However, the tilt rotation of each ring allows flexibility for the ligand system 2 to adjust to the coordination requirements of different metal atoms.

The ethene-backbone also gives a different symmetry to the ligand system 2. The $\mathrm{C}_{2 v}$ symmetry (if all the hydroxy groups are on the same side) makes two kinds of "proximal" relationships: "geminal" and "vicinal." Meanwhile, calix[4]arene has $\mathrm{C}_{4 \mathrm{v}}$
symmetry and has only one kind of "proximal" relationship between two neighboring aryl rings.
2.A.3. Tilting Angle of Each Ring. Although each ring in parent ligand 2 (as well as in the para-tert-butylated analogue or the ortho-propylated ligand 7) rotates freely in solution phase, the solid-state structure of 2 suggests certain conformational preferences. Unlike calix[4]arenes, which are always found in the "cone" conformation in crystal structures, ${ }^{1}$ the crystal structure of 2 reveals a "two-up/two-down" conformation, with or without the para-tert-butyl groups (Figure 2.2) ${ }^{2}$.

Figure 2.2. Hydrogen-bonding illustrations based on the crystal structures:
(a) tetrakis(2-hydroxyphenyl)ethene $\mathbf{2}^{2}$;
(b) para-tert-butylcalix[4]arene ${ }^{1}$.

In the calix[4]arene system, the cyclic hydrogen bonding array among the four hydroxy groups is the major factor stabilizing this particular "cone" conformation. In the tetrakis(2-hydroxyphenyl)ethene system, in contrast, intramolecular hydrogen bonding is seen only pairwise: between each geminal pair of hydroxy groups. The intermolecular hydrogen bonding then forms from an infinite one-dimensional array.

Cyclic intramolecular hydrogen bonding could form theoretically in the tetrakis(2-hydroxyphenyl)ethene system, if the aryl rings tilt to a certain degree. The ligand, however, seems to prefer to have the aryl rings as perpendicular to the olefin plane as possible, rather than deviating markedly from the perpendicular. When the rings
are all roughly perpendicular, the distance between the vicinal pair of hydroxy groups is too great to allow hydrogen bonding.

The cyclic bridging among the four aryloxy groups is, however, attained when the protons are replaced with stronger bridging groups. For example, the alkyl aluminum complex of 2 (Figure 2.3) forms such a cyclic structure. ${ }^{2}$ The aryl rings are nearly perpendicular to the olefin plane. The longer Al-O bond lengths make the cyclic structure possible while keeping the aryl rings nearly perpendicular.

Figure 2.3. Ethyl aluminum complex of 2 ( $\mathrm{R}=\mathrm{Me}$ or Et ).
2.A.4. Classification of Ligand Conformations. Theoretically, the tetrakis(2hydroxyphenyl)ethene framework can take five different basic conformations: "all-up," "geminal up/down," "vicinal up/down," "alternating up/down," and "three-up/one-down" (Figure 2.4). All patterns have been observed in the metal derivatives obtained from the ortho-propylated ligand 7 or dialkylated ligands 3E or 3Z (Chapters 3 and 4).

Figure 2.4. Different conformations of tetrakis(2-hydroxyphenyl)ethene.

Although the "all-up" case is further classified in calix[4]arene cases according to the tilting of the rings and the resultant overall symmetry, such further classification of the "all-up" case is not discussed for the tetrakis(2-hydroxyphenyl)ethene system in this thesis.

## 2.B. Direction of the Coordination Studies

The focus of the initial coordination studies of the new tetrakis(2hydroxyphenyl)ethene system as a potential surface-model system was placed on the construction of structural models for heterogeneous catalytic species. Supported ZieglerNatta olefin polymerization catalysts became the special target.
2.B.1. Supported Ziegler-Natta catalysts. Supported Ziegler-Natta catalysts, typically $\mathrm{TiCl}_{4}$ supported on silica or $\mathrm{MgCl}_{2}$ activated by alkylaluminum reagents, are still most widely used in industrial olefin polymerization. ${ }^{3}$ Many researchers have proposed structures for the active site(s) of these catalysts, but their heterogeneous nature has prevented their true structure from being determined.

It has been suggested that the catalytic centers of such systems consist of several metal atoms (typically $\mathrm{Ti}, \mathrm{Mg}$, and possibly Al ) bridged with halide or other ligands, including some from solid supporting matrices. Such constructions are considered capable of forming stereoregulating catalytic centers to produce, for example, isotactic poly- $\alpha$-olefins (Figure 2.5). ${ }^{4}$

In response to this proposal, the focus of the metal coordination studies using the modified tetrakis(2-hydroxyphenyl)ethene ligands was placed on the development of polymetallic systems by using the following three metals: $\mathrm{Ti}(\mathrm{IV}), \mathrm{Mg}$ (II), and $\mathrm{Al}($ III). Hetero-polymetallic species, in which different metal atoms combine to form one discrete complex, were of special interest as potential catalytic site models for silica- and $\mathbf{M g C l}_{2}-$ supported Ziegler-Natta catalysts.

#### Abstract

2.B.2. Aryloxide-based ligands in olefin polymerization. Titanium or zirconium complexes of some sterically hindered chelating bisaryloxide ligands are known to be good olefin polymerization precatalysts. Articles about and patents for such complexes appeared from 1987-1998, describing aryloxide-based bidentate ligands as one possible post-metallocene support-ligand for $\alpha$-olefin polymerization catalysts. Schaverien et al. in 1995 compared ethene polymerization activity by Group 4 complexes of various hindered bisaryloxides. ${ }^{5}$ The review by Gibson et al. in 1999 summarized the bisphenoxides as one successful post-metallocene system for Group 4 catalysts. ${ }^{6}$ Figure 2.6 shows the representative examples of such bisaryloxide precatalyst complexes that appeared in Gibson's review.

Steric hindrance is important to protect the aryloxide oxygen atoms or the central cationic metal atom from unwanted aggregation or interactions with co-catalysts or other species. Extra donors seem useful for both steric protection and electronic tuning of the catalysts, as are incorporated into those in the second row of Figure 2.6. Still, these bisaryloxides do not provide a well-defined single site catalyst, as indicated by the broad polydispersity of the product polyethenes. ${ }^{5}$

The review by Gibson also cited a few half-metallocene complexes with a pendant alkoxide donor. The system reported by Marks et al. had a phenoxide donor that showed very high activity (Figure 2.7).

Figure 2.7. Half-metallocene with phenoxide pendant group by Marks (1997).

Such phenoxide-based systems are, however, not the most promising in the latest studies of post-metallocene olefin polymerization catalysts. The ligands for the "hottest" post-metallocene catalysts all contain nitrogen-based donors, especially imines. ${ }^{7}$ Many of the imine-based ligands are effective with late transition metals, many of which are neutral species. Some of these catalysts accomplish polymerization productivity higher than that of the metallocene catalysts. These systems also allow structural fine-tuning of the catalysts for molecular weight control and co-polymerization degree.

Chapter 2 page 53

Nevertheless, in combination with the polymetallic "nucleation" and the potential surface-mimic template, these preorganized phenoxide ligands may still be interesting as polymerization catalyst templates. The modified tetrakis(2-hydroxyphenyl)ethene ligands do not exert much steric hindrance, but constructing polymetallic catalytic sites may replace the requirement for steric protection (the polymerization-related investigation of the metal derivatives will be discussed in Chapter 5).

## 2.C. General Approach

Our basic strategy for investigating the coordination chemistry of these ligand systems was first to prepare single-kind metal complexes of each ligand, with a special focus on the ligands 7 and 3 E , using metal reagents of $\mathrm{Ti}(\mathrm{IV}), \mathrm{Mg}$ (II), and Al (III). The basic connectivity patterns and chemical behavior were examined for each case. Construction of hetero- or mixed-polymetallic complexes was then attempted, starting with some of the single-kind metal complexes. The hetero-polymetallic combinations were also among the above-mentioned three metals. Chapter 3 discusses the coordination studies using tetrakis(2-hydroxy-3-proppylphenyl)ethene 7. Chapter 4 then covers the derivatives of $E$ - and $Z$ - bis(2-hydroxyphenyl)-bis(2-methoxyphenyl)ethene 3E and 3Z.

### 3.0. Introduction

This chapter describes the synthesis, structure, spectroscopic features, and chemical behavior of metal complexes derived from tetrakis(2-hydroxy-3propylphenyl)ethene 7. We focused on the creation of homo- and hetero-polymetallic complexes by using the metals Mg (II), $\mathrm{Ti}(\mathrm{IV})$ and/or $\mathrm{Al}($ III ) potentially relevant to the proposed catalytic-site structure of heterogeneous Ziegler-Natta catalysts (see Chapter 2).

Ligand 7 proved its potential to form various discrete polymetallic complexes. Figure 3.1 provides a list of the structurally characterized complexes that appear in this chapter. All of the complexes depicted, except for those in parentheses, have been characterized by X-ray crystallography.

The introduction of the ortho-propyl groups on the parent ligand framework (2) obviously contributed to the development of various discrete and characterizable complexes. The formation of many discrete complexes results from the orthosubstituents' effect, reducing the possibility of random aggregation or "collapsing" (i.e., forming a "sandwich-type" complexes, which is a dead-end in the search for oxo-surface mimics) of the complexes. The improved solubility resulting from the ortho-alkylation also enabled sufficient spectroscopic characterization and an expanded investigation of the chemistry of the metal complexes.

Various coordination patterns were observed by using different metal elements. The coordination patterns are determined by the metal's oxidation number, the number of available coordination sites, and the number and the size of the ancillary ligands. Additional coordination patterns were observed for some of the mixed-metal systems.

Generally speaking, the phenolato-oxygen atoms often bridge between two metal atoms. This bridging nature of the oxygen atoms is the major contributor in the formation of rigid oxo-surface like structures in the metal derivatives. When the oxygen atoms are not used for bridging, the aryloxy groups functions pairwise to form geminal or vicinal up/down structures (as was observed in many Ti complexes). The metals are rather preorganizing the ligand backbone than the ligand is preorganizing the metals.

Hence, not all the metal elements lead to the formation of oxo-surface-like complexes of potential use for surface-model studies. However, even these metal atoms can still be placed on the "all-up" shaped ligand through the preparation of mixed-metal (hetero-polymetallic) systems. For example, both $\mathrm{Ti} / \mathrm{Mg}$ and $\mathrm{T} / \mathrm{Al}$ hetero-polymetallic complexes maintained the Ti atom on an oxo-surface-like platform of the ligand.

In this chapter, we first describe the homo-polymetallic complexes composed of $\mathrm{Mg}, \mathrm{Ti}, \mathrm{Al}$, or Na atoms. The hetero-polymetallic systems of $\mathrm{Mg} / \mathrm{Al}, \mathrm{Mg} / \mathrm{Ti}$ and $\mathrm{Al} / \mathrm{Ti}$ combinations will follow.

### 3.1. Homo-polymetallic Complexes

#### Abstract

Many discrete homo-polymetallic complexes were prepared from the orthopropylated tetrakis(2-hydroxyphenyl)ethene 7 that contains $\mathbf{M g}$ (II), $\mathrm{Ti}(\mathrm{IV})$ or Al (III) atoms. Ligand 7 exhibits various conformation and coordination patterns, which, in many cases, are unique to the metal. Varieties are also often observed within the same metal species: different ancillary groups on the metal atom sometimes result in different connectivity and reactivity in the product. For example, $\mathrm{Et}_{3} \mathrm{Al}$ and $\mathrm{Et}_{2} \mathrm{AlCl}$ apparently produce differently coordinated polynuclear aluminum complexes.

The general synthetic routes are the following: (1) addition of a metal halide reagent to ligand 7 with or without pre-deprotonation, and (2) addition of an alkyl metal reagent to ligand $\mathbf{7}$ for protonolysis. The reactions were all performed in a drybox and at room temperature.

For the $\mathbf{M g}$ (II) complexes, route (2) was used exclusively with various Grignard reagents. For the $\mathrm{Ti}(\mathrm{IV})$ complexes, route (1) was taken for the reagents $\mathrm{TiCl}_{4}, \mathrm{TiBr}_{4}$ and $\mathrm{CpTiCl}_{3}$, and route (2) was used for $\mathrm{TiBn}_{4}$. For the $\mathrm{Al}(\mathrm{III})$ complexes, route (2) was exclusively used with alkyl aluminum reagents $\mathrm{R}_{3} \mathrm{Al}\left(\mathrm{R}=\mathrm{Me}\right.$ or $\mathrm{Et}^{2}$ ), $\mathrm{Et}_{2} \mathrm{AlCl}$ and $\mathrm{EtAICl}_{2}$. For a comparison, a low-valent, non-oxophilic $\mathrm{Na}(\mathrm{I})$ complex, often used as a deprotonated precursor for route (1) reactions, was also structurally examined.

### 3.1.1. Mg Complexes

### 3.1.1.A. MgX Complexes of 7

Deprotonation of the tetraphenol 7 by four equivalents of a Grignard reagent gives a series of trinuclear magnesium complexes (Scheme 3.1). The Grignard reagent can be anything that produces a volatile and removable hydrocarbon R'H. R' was methyl for complex 25, allyl for 26, and benzyl for 27.

$25 \mathrm{X}=\mathrm{Cl}, \mathrm{R}_{2} \mathrm{O}=\mathrm{THF}$ (X-ray)
$26 \mathrm{X}=\mathrm{Br}, \mathrm{R}_{2} \mathrm{O}=$ THF (X-ray)
$27 \mathrm{X}=\mathrm{Cl}, \mathrm{R}_{2} \mathrm{O}=\mathrm{Et}_{2} \mathrm{O}$ (EA)

Scheme 3.1. Trinuclear magnesium complexes from 7.

Although the reaction conditions were all similar, the purification procedure varied for complexes $\mathbf{2 5}$ to 27 . In the case of the $\mathbf{M g}(\mathrm{Cl})$ complex $\mathbf{2 5}$, the product was less soluble in THF than the byproduct, $\mathrm{MgCl}_{2}$ (thf). This factor made it possible to crystallize the product from a hot THF solution of the $1: 1$ mixture of $\mathbf{2 5}$ and $\mathrm{MgCl}_{2}$ (thf). The mother liquor after the first crystallization, still containing some product but now with a higher concentration of $\mathrm{MgCl}_{2}{ }^{\circ}(\mathrm{thf})_{\mathrm{n}}$, was evaporated and triturated with toluene. In toluene, the solubility is higher for the product 25 than the inorganic byproduct, in contrast to THF. Upon repeating the crystallization of the toluene extract, $73 \%$ of the purified product was isolated in total. The amount of $\left[\mathrm{MgCl}_{2}(\right.$ thf $\left.)\right]$ as a minor component increased in later crops of crystals.

In the case of the $\mathrm{Mg}(\mathrm{Br})$ complex 26, the product was more soluble in THF than was $\mathrm{MgBr}_{2} \cdot(\text { thf })_{2}$. The byproduct $\mathrm{MgBr}_{2}($ thf $)$ crystallized out in the first crystallization from THF. The crystals of the product 26 were obtained from the mother liquor from the first crystallization, after removal of THF and crystallization from toluene/hexanes. The crystals contained some amount of a byproduct that was most likely a dibenzylated species, analogous to complex 29 (vide infra). This overreaction is attributed to the use of excess Grignard reagent in this reaction. With exactly four equivalents of Grignard reagent, the reaction is expected to give 26 quantitatively.

The structures of the compounds 25 and 26 were determined by X-ray crystallography (see Section 3.1.1.C). Complex 27 gave an elemental analysis and ${ }^{1} \mathrm{H} /{ }^{13} \mathrm{C}$ NMR spectroscopy consistent with the given structure.

The introduction of the ortho-propyl substituent at the 3-position of each aryl ring contributes to the formation of the discrete trinuclear structure. According to Verkerk, with no ortho-substituents (i.e., in the case of 2), the same reaction conditions as that for the $\mathbf{M g}(\mathbf{C l})$ complex 25 gave a half-collapsed pentamagnesium structure (Figure 3.2).' The steric influence of the propyl groups in 7 must be effective enough to avoid such aggregation.

Figure 3.2. Verkerk's collapsed $\mathbf{M g}$ salt of parent ligand 2.

Although we initially expected the ligand to hold all four magnesium atoms on the "all-up" tetraaryloxy platform, one equivalent of $\mathrm{MgCl}_{2}{ }^{\circ}(\mathrm{thf})$ is excluded from the system to form the trinuclear structure. It seems that the steric effect of the propyl groups not only prevents the collapse of two molecules but also prevents the ligand from retaining all four Mg atoms.

The structure of the tri-magnesium complexes on the oxo-surface-like ligand platform was promising as a potential surface model and as a starting point to construct different surface models. Subsequently, we found that complex 25 is also an excellent starting material to produce hetero-polymetallic complexes (vide infra).

### 3.1.1.B. MgR Complexes of 7

In the presence of excess methyl magnesium chloride, the halides on the terminal magnesium atoms of $\mathbf{2 5}$ are replaced with methyl groups to give the $\mathbf{M g}\left(\mathrm{CH}_{3}\right)$ complex 28 (Scheme 3.2). Complex 28 was obtained either by addition of six equivalents of methyl magnesium chloride to the protonated ligand 7, or by adding two equivalents of methyl magnesium chloride to the preformed magnesium derivative 25. Both routes cleanly gave the product 28 . This complex was also characterized crystallographically (Section 3.1.1.C).

Scheme 3.2. Direct and indirect routes to the $\mathrm{Mg}\left(\mathrm{CH}_{3}\right)$ complex 28.

As is known for Grignard reagents and other magnesium compounds in solution, the alkyl and halide anions exchange in equilibrium. ${ }^{2}$ Apparently, the equilibrium was shifted to the direction of the formation of $\mathrm{MgCl}_{2}$ and the dialkylated product 28. The self-aggregation of $\mathrm{MgCl}_{2}$ to precipitate, bringing itself out of the system, is probably the driving force for the completion of the reaction.

Scheme 3.3. Suggested equilibrium to bring 25 to 28.

When six equivalents of benzyl Grignard reagents are added to ligand 7 in diethyl ether medium, dibenzyl compound 29 is obtained (Scheme 3.4). The 'H NMR spectrum of the crystallized material in THF-d indicates that 29 retains only one equivalent of coordinating ether. This one molecule of ether is probably at the central position. The large size of the terminal benzyl groups may prevent the coordination of ether molecules. It is not confirmed, however, whether or not the benzyl groups have a hapticity of greater than one.

Scheme 3.4. $\mathbf{M g}(\mathrm{Bn})$ complex 29.

### 3.1.1.C. Crystallographic Features of the Tri-Magnesium Complexes

The X-ray crystallographic determination of the solid-state structures of complexes 25, 26 and 28 were obtained (see Appendices A-3 and A-4 for details). Figure 3.3 shows the ORTEP plot of complex 25 . The data set was too weak to be refined to the adequate level, yet the basic connectivity of the atoms was provided.

Figure 3.3. X-ray crystallographic structure of 25.

Both complexes 26 and 28 gave good quality crystal structures (Figure 3.4 and 3.5). As shown in the ORTEP plots, the structures of these three complexes are very similar. Selected bond lengths and angles are provided in Table 3.1.

The conformation of the ligand framework in each complex is hardly affected by the different groups on the terminal Mg atoms. In these structures, the four aryl rings are nearly perpendicular to the olefin plane. The "ring torsion against olefin plane" in the table shows the relative angle of the C11-C16 ring and C21-C26 ring against the olefin double bond. These torsional angles are close to $90^{\circ}$. The deviation from perpendicularity is approximately $3^{\circ}$ and $1^{\circ}$, respectively.

Figure 3.4. X-ray crystallographic structure of $\mathbf{2 6}$. With side and top views.

Figure 3.5. X-ray crystallographic structure of 28. With side and top views.

| Torsional Angles of Olefin Plane (deg) |  |  |
| $\mathrm{Cll}-\mathrm{Cl}-\mathrm{Cl}^{\prime}-\mathrm{ClI}^{\prime}$ | -175.1(10) | 175.7(3) |
| $\mathrm{Cll}-\mathrm{Cl}-\mathrm{Cl}{ }^{-} \mathrm{C} 21{ }^{\prime}$ | 0.3(5) | -0.72(16) |

Ring Torsion Angles* (deg)

| $\mathrm{Cl}-\mathrm{Cl}-\mathrm{Cl1}-\mathrm{Cl2}$ | $93.2(9)$ | $91.1(2)$ |
| :--- | ---: | ---: |
| $\mathrm{Cl}-\mathrm{Cl}-\mathrm{Cl1}-\mathrm{Cl} 6$ | $-87.3(9)$ | $-91.3(3)$ |
| $\mathrm{Cl}^{\prime}-\mathrm{Cl}-\mathrm{C} 21-\mathrm{C} 22$ | $-90.4(9)$ | $-94.1(2)$ |
| $\mathrm{Cl}-\mathrm{Cl}-\mathrm{C} 21-\mathrm{C} 26$ | $91.3(9)$ | $88.5(3)$ |

*Ring torsion angle is defined as the torsional angle of CX1-CX2 bond or CX1-CX6 bond (in this case, $\mathrm{X}=1$ or 2 ) in an aromatic ring and the olefin $\mathrm{C}=\mathrm{C}$ bond (in this case $\mathrm{Cl}-\mathrm{Cl}$ '). The aryl ring CX1~CX6 is perpendicular to the olefin plane when $[\mathrm{C}=\mathrm{C}]-$ CX1-CX2 and [C=C]-CX1-CX6 are $\pm 90^{\circ}\left([\mathrm{C}=\mathrm{C}]\right.$ is either $\mathrm{Cl}-\mathrm{Cl}{ }^{\prime}$ or $\mathrm{Cl}{ }^{\prime}-\mathrm{Cl}$ in this case).

Chapter 3 3.1.1. Mg Complexes page 68

As is observed in the side views of $\mathbf{2 6}$ and $\mathbf{2 8}$, the $\mathbf{~ M g}$ atoms are located above the $\mathrm{O}_{4}$ plane. The central Mg atom ( Mg 1 ) is only slightly above the reference plane, while the two crystallographically equivalent terminal $\mathbf{M g}$ atoms (Mg2) are considerably more "uplifted." Table 3.2 summarizes the distance of the central or terminal $\mathbf{M g}$ atoms from the $\mathrm{O}_{4}$ plane in $\mathbf{2 5}, 26$ and 28.

Table 3.2. Distance from the least-squares plane of $\mathrm{Ol}-\mathrm{O} 2-\mathrm{Ol}^{\prime}-\mathrm{O} 2^{\prime}(\AA)$.

|  | 25 | 26 | 28 |
| :--- | ---: | :---: | :---: |
| $M_{\text {central }}(\mathrm{Mg} 1)$ | 0.15 | 0.148 | 0.147 |
| $\mathrm{Mg}_{\text {cemminal }}(\mathrm{Mg} 2)$ | 0.60 | 0.616 | 0.688 |

The terminal Mg atoms are more "uplifted" partly because of the van der Waals repulsion between the equatorial THF and the neighboring aryl rings. When the terminal groups are " $\mathrm{AlEt}_{2}$ " instead of " $\mathrm{MgCl}(\mathrm{thf}$ )," as in the complexes 41 and 42 (vide infra, Section 3.2.1.A), the terminal aluminum atoms are significantly closer to the $\mathrm{O}_{4}$ plane than the terminal magnesium atoms in complexes 25,26 , and 28.

Still, in both all-magnesium and aluminum/magnesium complexes, the central magnesium atom is lower than the terminal metal atoms. The central $\mathbf{M g}$ atom takes pseudo-octahedral geometry with the four phenolato-oxygen atoms at the equatorial positions. Although the central Mg atom is located slightly "away" from the olefin double

Chapter 3 3.1.1. Mg Complexes page 69
bond at the axial position, the interatomic distance between the central Mg and the olefin carbon atom ( $2.58 \AA$ ) suggests a weak interaction between them. Presumably, this interaction with the olefin $\pi$-electrons contributes to the "flattening" of the central $\mathbf{M g}$ atom.

The pseudo-tetrahedral geometry of each terminal Mg atom is distorted in two ways: firstly, at the $\mathrm{O} 1-\mathrm{Mg} 2-\mathrm{O} 2$ angle ( 83 to $86^{\circ}$ ) due to constraints in the ligand structure; and secondly, at the X group $\left(\mathrm{Br}\right.$ or $\left.\mathrm{CH}_{3}\right)$, which is angled away from the central THF by van der Waals repulsion.

Disorder was noted for the terminal THF molecules. The terminal THF has two possible orientations: the illustrations in Figure 3.4 and 3.5 represent only one of them. Details can be found in Appendices A-3 and A-4.

There are very few reported examples of crystallographically characterized interactions between a $\mathbf{M g}$ atom and $\pi$ electrons of carbon-carbon double/triple bonds. Mach et al. reported the titanocene diacetylide "tweezer" complex shown below (Figure 3.6). ${ }^{3}$

Figure 3.6. The "tweezer" complex by Mach et al. ${ }^{3}$
Bond distances: $\mathrm{C}-\mathrm{C}=1.22 \AA, \mathrm{Mg}-\mathrm{C}_{\text {inner }}$ (average) $=2.27 \AA, \mathrm{Mg}-\mathrm{C}_{\text {outce }}$ (average) $=2.46 \AA$.

The $\mathrm{Mg}-\mathrm{C}_{\text {otefin }}$ distances found in 26 and 28 are longer than those in the Mach's complex, but they are still comparable to some of the known $\mathrm{Mg}-(\mu-\mathrm{C})$ bond lengths in $\mathrm{Cp}-\mathrm{Mg}$ or indenyl-Mg complexes cited in this reference.

### 3.1.1.D. Spectroscopic Features of the Tri-magnesium Complexes

The 'H-NMR spectroscopic features of tri-magnesium complexes 25, 26, 27, 28 and 29 are very similar to each other. When compared in the same deuterated solvent (THF-d $\mathbf{d}_{8}$ ), the ligand framework signals appear at very similar positions. The similarity in the solution phase suggests that the electronic effects of the different groups attached to the terminal Mg atoms is minimal on the ligand framework, as was observed for the solid state structure of these complexes.

For all five complexes, the four aryl rings (including the propyl substituent) are all equivalent. The $\alpha-\mathrm{CH}_{2}$ and $\beta-\mathrm{CH}_{2}$ methylene protons in each propyl group are diastereotopic (i.e., the protons in each $\mathrm{CH}_{2}$ group are non-equivalent) due to the rigid structure. This feature contrasts with that of the enantiomeric $\alpha-\mathrm{CH}_{2}$ and $\beta-\mathrm{CH}_{2}$ methylene protons in the free phenolic ligand, in which each aryl ring is freely rotating.

As an example, the 'H NMR spectrum of complex 25 in THF- $d_{8}$ is provided in Figure 3.7-a. The THF molecules that were coordinating to the complex are liberated upon dissolving in THF- $\mathrm{d}_{8}$, completely being replaced with the deuterated solvent. For comparison, the spectrum of the free phenolic ligand 7 is given as Figure 3.7-b. Complex 25's signal pattern in the aromatic region is quite similar to that of $\mathbf{7}$, but slightly shifted upfield. This difference is obviously due to the ionization of the OH groups to aryloxides, which become more electron rich and provide more electron density to the ring.

The chemical shifts of the alkylmagnesium groups in $28\left(\mathrm{CH}_{2} \mathrm{Ph}\right)$ and $29\left(\mathrm{CH}_{3}\right)$ are comparable to the shifts of corresponding alkyl groups of typical Grignard reagents, only slightly downfield-shifted. For example, the chemical shift of the " $\mathrm{CH}_{2} \mathrm{Ph}$ " proton of 28 is 1.46 ppm while $\mathrm{PhCH}_{2} \mathrm{MgCl}(\text { (ether })_{\mathrm{n}}$ appears at 1.33 ppm in THF - $\mathrm{d}_{8}$, and the chemical shift of the ${ } \mathrm{CH}_{3}$ " group in 29 is -1.53 ppm while $\mathrm{CH}_{3} \mathrm{MgCl}(\mathrm{th})_{\mathrm{n}}$ appears at -1.70 ppm . $^{\text {a }}$

[^4]Chapter 3 3.1.1. Mg Complexes page 71

Figure 3.7. ${ }^{1}$ HMR spectra of (a) $\mathbf{2 5}$ and (b) $\mathbf{7}$ in THF-d ${ }_{8}$.

In a non-coordinating medium, such as $\mathrm{C}_{6} \mathrm{D}_{6}$, the coordinating THF molecules on 25 remain intact on the complex. The central and terminal THF molecules are clearly differentiated in the ${ }^{1} \mathbf{H}$ NMR spectrum (Figure 3.8).

Figure 3.8. ${ }^{1} \mathrm{H}$ NMR spectrum of 25 in $\mathrm{C}_{6} \mathrm{D}_{6}$.

In $\mathrm{C}_{6} \mathrm{D}_{6}$, the central-THF signals are sharp and highly downfield-shifted. The chemical shifts are 4.92 and 2.34 ppm , whereas free THF appears at 3.57 and 1.40 ppm . On the other hand, the terminal THF's are broad and upfield-shifted ( 2.86 and 0.76 ppm ).

The upfield shift of the terminal THF ligands is best explained as an anisotropic effect exerted by the neighboring aromatic rings. Each terminal THF is placed in between a pair of geminal aromatic rings, in the shielding region of both rings. Figure 3.9-a provides some idea about the position of the terminal THF ligand from the top view. Figures 3.9-b and -c are different perspective ORTEP plots of complexes 26 and 28, in which the positions of a terminal THF and one aryl ring are viewed.

Figure 3.9. A terminal THF in the shielding region of neighboring aryl rings.
(a) Top view with perpendicular aryl rings. Propyl groups are omitted for clarity. The thin dotted lines show the position of the aryl rings when they are coplanar with the double bond.
(b) A terminal THF and one aryl ring in 26's ORTEP plot.
(c) A terminal THF and one aryl ring in 28's ORTEP plot.

Why the central THF appears so downfield is less clear at a glance. The coordination to a $\mathbf{M g}$ (II) ion by itself is definitely not sufficient to cause the signals to shift by ca. 1.3 ppm . For example, the THF molecules coordinated to the simple phenoxymagnesium chloride, $\left[\mathrm{PhOMgCl}(\text { thf })_{2}\right]_{2}$, appear at 3.62 and 1.15 ppm in $\mathrm{C}_{6} \mathrm{D}_{6}$, quite close to the chemical shifts of free THF.

Chapter 3 3.1.1. Mg Complexes page 74

The aryl rings are the only possible source of this deshielding effect. To examine the anisotropic effect of the aryl rings on the protons of the central THF molecule, the positions of the protons against each of the aryl rings were measured in the crystal structure of the $\mathrm{Mg}(\mathrm{Br})$ complex 26, and compared with the theoretical calculation of shielding/deshielding effects of a benzene ring by Haigh and Mallion (Figure 3.10). ${ }^{4}$

Figure 3.10. Isofield diagram of ring current effects by a benzene ring on a proton nucleus, provided by Haigh and Mallion. ${ }^{4}$ The unit of the axes is benzene radius ( $1.39 \AA$ ), and the unit of shifts in the chemical shift is ppm.

Figure 3.11-a summarizes the positions of $\alpha$-protons (light dots) and $\beta$-protons (dark dots) against each aryl ring in the crystal structure of complex 26. The two connected dots are of a pair protons on the same methylene group, pointing inward or outward. The $\alpha$-protons of the central THF are located in the deshielding region of each of the four aryl rings, although the distance is $5.4 \AA$ or longer to the centroid of each ring. According to the Haigh-Mallion diagram, the deshielding effect is still effective by ca. $\Delta 0.4 \mathrm{ppm}$ at $4 \AA$ and $\Delta 0.2 \mathrm{ppm}$ at $5 \AA$ along the $\rho$-axis. The additive effect of all the four rings may thus be noticeable. However, it is questionable if this effect alone can explain the shift of $\Delta 1.3 \mathrm{ppm}$ in this conformation.

If the central THF is positioned in a different way, the THF-protons accept the deshielding effect more efficiently. Presumably, the central THF is rotating in solution, while the crystal structure represents only the state in which it is placed orthogonal to the olefin double bond (Figure 3.11-b). If the central THF is placed along the olefin double bond axis, it brings the $\alpha$-THF protons closer to the plane of the adjacent ring (Figure 3.11-c). If the contribution of the latter state is not small, a larger deshielding effect is expected for the central THF than that suggested by the crystal structure (Figure 3.10-b).
(a)

Light dots: $\alpha$-protons. Dark dots: $\beta$-protons.
The oblique line is the border between the shielding and deshielding regions.

(b)

Central THF orthogonal to the $\mathrm{C}=\mathrm{C}$ bond

(c)

Central THF along the $\mathrm{C}=\mathrm{C}$ bond

Figure 3.11.
(a) Positions of the central THF protons against the ligand framework's aryl rings in the crystal structure of complex 26.
(b) Illustration of complex 26 from the top view, with the central THF oriented orthogonal to the olefin double bond of the ligand (as in the crystal state).
(c) Illustration of complex 26 from the top view, with the central THF aligned parallel to the olefin double bond of the ligand.

The ${ }^{1} H$ NMR spectrum of 25 in $\mathrm{C}_{6} \mathrm{D}_{6}$ shows additional differences between the central and terminal THF molecules. When excess free THF is present in $\mathrm{C}_{6} \mathrm{D}_{6}$ solution, only the terminal THF signals are averaged with free THF. The averaged signals of the free and terminal THF molecules appear as broad bands (both the $\alpha$ and $\beta$ protons). The central THF signals remain unaffected in the presence of excess free THF.

Chapter 3 3.I.I. Mg Complexes page 76

### 3.1.2. Ti Complexes

Most dinuclear titanium complexes of ligand 7 show a "two up/two down" ligand conformation, not an "all-up" oxo-surface-like structure. The "geminal up/down" complexes obtained from the reaction with titanium halides or alkyltitanium reagents are presented in the first three sections (3.1.2.A to 3.1.2.C), followed by a section about a 1 : 1 adduct of ligand 7 and $\mathrm{TiCl}_{4}$, the collapsed "sandwich-type" complex 32 (Section 3.1.2.D). Interestingly, the geminal up/down di- $\mathrm{TiCl}_{2}($ thf $)$ complex $\mathbf{3 0 a}$ showed isomerization behavior to a vicinal up/down analogue 30b: this chemical behavior will be discussed (Section 3.1.2.E). In the final section, the spectroscopic features of these titanium complexes will be discussed, with a focus on the significant effects caused by the tilting of aryl rings on the NMR chemical shifts (3.1.2.F).

### 3.1.2.A. Geminal Up/Down Complexes

The reactions of ligand 7 with two equivalents of titanium halides $\mathrm{TiCl}_{4}, \mathrm{TiBr}_{4}$ or $\mathrm{CpTiCl}_{3}$, after prior deprotonation, produced geminal up/down dinuclear complexes 30 , 33, and 34, respectively (Scheme 3.5). Although the reactions were fairly clean, minor impurities were always found in the crude products. The reaction with $\mathrm{TiCl}_{4}$ without prior deprotonation also resulted in producing a reasonably clean product (the no-base reaction was attempted for $\mathrm{TiCl}_{4}$ only).

When two equivalents of $\mathrm{TiCl}_{4}$ or $\mathrm{TiBr}_{4}$ were added to the trinuclear magnesium complex 25, similar geminal up/down complexes 30a and 33a were produced (Scheme 3.6). The only difference from 30 and 33 was that each Ti atom is coordinated by one THF molecule in complexes 30a and 33a, as was confirmed by ${ }^{1} \mathrm{H}$ NMR spectroscopy and X-ray crystallography (vide infra). The coordinating THF molecules came from the starting material. Use of the $\mathrm{Mg}(\mathrm{Br})$ (thf) complex 26, instead of the above-mentioned $\mathbf{M g}(\mathrm{Cl})$ (thf) complex $\mathbf{2 5}$, resulted in the same product, as was established for complex 30a.

The initial intention for performing the reactions between the magnesium salts $\mathbf{2 5}$ or 26 and $\mathrm{TiCl}_{4}$ was to obtain $\mathrm{Mg} / \mathrm{Ti}$ hetero-polymetallic species. However, no magnesium remained in the product.

Scheme 3.5. Geminal up/down titanium halide complexes.

Scheme 3.6. Geminal up/down titanium halide complexes, THF-solvated.

The reactions between the magnesium complex 25 and the titanium halides were also fairly clean, but the products were often accompanied by minor unidentified byproducts. A longer reaction time seemed to increase the impurities. $\mathrm{The} \mathbf{C p T i C l}$ complex 34 was difficult to obtain impurity-free in the bulk, although X-ray quality crystals were produced by careful crystallization.

The alkane elimination reaction between ligand 7 and two equivalents of $\mathrm{TiBn}_{4}$ also resulted in a geminal up/down complex (35, Scheme 3.7). The reaction was clean; crystallization was relatively easy and produced pure material in good yield.

Scheme 3.7. Geminal up/down benzyltitanium complex 35.

In the formation of these dinuclear titanium complexes, the ortho-propylation in ligand 7 again contributes to the formation of a non-aggregated discrete products. The parent tetrakis(2-hydroxyphenyl)ethene 2, with no alkyl substituents, does not give analyzable products under similar conditions, probably due to the poor solubility of the starting material, and possibly, the aggregation of the Ti adduct into oligomeric clusters.

### 3.1.2.B. Crystallographic Features of the Geminal Up/Down Ti Complexes

The structures of the complexes 30a, 33a, 34 and 35 were confirmed by X-ray crystallography.

The thf-solvated chloro complex 30a and the bromo analogue 33a show quite similar structural features (Figures 3.12 and 3.13). Each Ti atom assumes trigonal bipyramidal geometry in both cases, with the THF molecule and one aryloxy group at axial positions. The olefin plane of the ligand framework is slightly distorted. The aryl rings are tilted from the position perpendicular to the $\mathrm{C}=\mathrm{C}$ olefin plane (i.e., $\pm 90^{\circ}$ ) by $10^{\circ}-$ $30^{\circ}(30 \mathrm{a})$ or $7^{\circ}-35^{\circ}(33 \mathrm{a})$, as shown by the ring torsion angles. The direction of the tilting is helical: the top edge of one ring is over the bottom edge of the neighboring ring.

Figure 3.12. X-ray crystallographic structure of $\mathbf{3 0 a}$. The label for the aromatic carbon attached to OX is CX2.

The structures of the THF-free products 30 and 33 are considered to be analogous to 30a and 33a, based on their similar ${ }^{\text {'H NMR spectroscopic features (vide infra). }}$ Crystallization of the non-THF complexes 30 and 33 was difficult due to solubility problems. In contrast to the THF-solvated versions, the non-solvated analogues had "inconsistent" solubility in toluene and other non-coordinating hydrocarbon solvents. After triturating with toluene, the residual solid after removal of toluene from the triturate

Chapter 3 3.1.2. Ti Complexes page 81
does not become completely soluble again. Removing the volatiles or even concentrating the toluene solution accelerates the aggregation or disproportionation of the complexes to form less soluble species, a process that may be irreversible. The coordination by THF in 30a apparently helps to prevent such aggregation.

In contrast to the tilting aryl rings in 30a or 33a, the aryl rings in the di- CpTiCl complex 34 and the di- $\mathrm{TiBn}_{2}$ complex 35 are nearly perpendicular (Figures 3.14 and 3.15). The ring tilting angles are $5^{\circ}-8^{\circ}(34)$ and $6^{\circ}-10^{\circ}(35)$ from perpendicularity, which are significantly smaller than those of 30a and 33a. The major difference between the former two complexes and the latter two complexes is in the coordination geometry of each Ti atom, trigonal bipyramidal for the former, and tetrahedral (35) or pseudotetrahedral (34) for the latter. The olefin distortion degree is also small for 34 and 35. Probably the tetrahedral geometry of Ti atoms on the geminal up/down configuration is more "fitting" to the ligand framework, without requiring as much distortion or ringtilting as the trigonal bipyramidal cases require.

In the crystal structure of the benzyltitanium complex 35, the orientation of each pair of benzyl groups (on each titanium atom) provides a good example of a so-called "tilted (or distorted) T-shaped" aromatic-aromatic interaction, the most favorable interaction of the benzene dimer, according to Jorgensen et al. ${ }^{5}$ Although no detailed distances and angles are provided in the reference, the ring center-ring center distance of $4.99 \AA$ and the relative positions of the two interacting benzene rings illustrated in the reference (Figure 3.16) are remarkably similar to the proximal benzyl/benzyl relationship in the structure of 35 . The centroid-centroid distance in 35 is $4.95 \AA$, quite close to the Jorgensen's "tilted T" relationship. The perspective view of 35 in Figure 3.15-b gives a good idea of the orientation of these two phenyl rings.

Figure 3.16. "Tilted or distorted Tstructure" of benzene dimer, by Jorgensen et al. R is the ring center-ring center distance and $E$ is the interaction energy in kcal/mol.

### 3.1.2.C. Spectroscopic Features of the Geminal Up/Down Ti Complexes

i) Di-(TiX ${ }_{2}$ ) Complexes. Complexes 30a and 33a, the geminal up/down di-TiCl $\mathbf{2}_{2}$ (thf) and di- $\mathrm{TiBr}_{2}$ (thf) complexes, showed very similar ${ }^{\mathbf{1}} \mathrm{H}$ NMR spectra. The spectra of the non-THF solvated analogues $\mathbf{3 0}$ and $\mathbf{3 3}$ were also quite analogous.

Figure 3.17 presents the ${ }^{1} \mathrm{H}$-NMR spectrum of 30 a in $\mathrm{C}_{6} \mathrm{D}_{6}$ at $25^{\circ} \mathrm{C}$ as an example. The four aryl rings are all equivalent, indicating that the helical ring tilting observed in the X -ray structure is not retained in solution phase at room temperature. Helical ring tilting in both directions may co-exist, but each must be alternating rapidly in solution (Scheme 3.8). The basic geminal up/down structure remains unchanged, for the $\alpha$ - and $\beta$-methylene groups of the propyl chains show diastereotopic features (i.e., splitting), indicating the rigidity of the structure.

The characteristic feature of the spectrum is that one aromatic proton signal is highly downfield-shifted. This double doublet (dd) signal appears at 7.88 ppm for $\mathbf{3 0 a}$. This downfield shift is remarkable compared to that of the tri-magnesium complexes 25 29: the most downfield signal of 25 , for example, is 7.01 ppm (Figure 3.8). This downfield dd is assigned to the $\mathrm{H}-6$ proton of each aryl ring because this position is anisotropically most influenced by the ring rotation or tilting.

Because a similar kind of highly downfield dd signal is commonly observed in many (but not all) "up/down" metal complexes, the proximity of an aromatic proton to the metal atoms was first suspected as the source of the deshielding effect. With geminal or vicinal "up/down" structures, H-6, the aromatic protons at the 6-position (H16, H26, H36 and H46: see Figure 3.18) are brought spatially close to the metal coordination site on the opposite side. Note that in the magnesium complexes 25-29, no aromatic proton is near the coordination site.

Figure 3.17. ${ }^{1} \mathrm{H}$-NMR spectrum of $\mathbf{3 0 a}\left(\mathrm{C}_{6} \mathrm{D}_{6}\right)$.

Scheme 3.8. Proposed solution behavior of 30a. The thick arrows represent the direction of the helices.

Table 3.3. Non-bonding interatomic distances between the proton at 6 -position of each ring.

| Interatomic distance $(\AA)$ |  |
| :--- | :--- |
| $\mathrm{Ti} \cdots \mathrm{H}$ |  |
| $\mathrm{Til} \cdots \mathrm{H} 36$ | 3.93 |
| $\mathrm{Til} \cdots \mathrm{H} 46$ | 3.67 |
| $\mathrm{Ti} 2 \cdots \mathrm{Hl} 6$ | 3.82 |
| $\mathrm{Ti} 2 \cdots \mathrm{H} 26$ | 4.14 |
| $\mathrm{H} \cdots \mathrm{Cl}$ |  |
| $\mathrm{H} 36 \cdots \mathrm{Cl} 2$ | 2.90 |
| $\mathrm{H} 46 \cdots \mathrm{Cl} 2$ | 3.10 |
| $\mathrm{H} 16 \cdots \mathrm{Cl} 4$ | 3.32 |
| $\mathrm{H} 26 \cdots \mathrm{Cl} 4$ | 2.85 |

Figure 3.18. Selected atom labels in the complex 30a.

The possibility of the H-6 proton having an agostic interaction ${ }^{6}$ with the closest titanium atom and the possibility of hydrogen bonding to the closest chloride ligand were examined for 30a. Table 3.3 presents the distances between an $\mathrm{H}-6$ and the closest Ti or Cl atoms in 30a. The relevant atom labels are provided in Figure 3.15. Based on these non-bonded interatomic distances, no meaningful interaction is expected between any $\mathbf{H}$ 6 and the Ti atoms nor between $\mathrm{H}-6$ and any Cl atoms. $\mathrm{The} \mathrm{Ti} \cdots \mathrm{H}$ distances are too long to allow any interaction, and the $\mathrm{H} \cdots \mathrm{Cl}$ distances are no shorter than the van der Waals distances.

A more plausible explanation for the highly downfield shift is that the tilting of the aryl rings causes a change in the local magnetic environment. Unlike aryl rings in the magnesium complexes, the aryl rings in complex 30a are not perpendicular to the olefin plane in the crystal structure. In solution, as discussed earlier, the direction of the helical ring tilting should be switching rapidly from one way to another (Scheme 3.8).

Nevertheless, the 'H NMR spectrum will reflect mainly the two tilted extremes and not the all-perpendicular transition state. The two tilted extremes are enantiometic; therefore, the ${ }^{\mathbf{}} \mathrm{H}$ NMR signals from each are identical. These tilted extremes are assumed to be close to those observed in the crystal structure.

To examine the effect of the ring tilting on the magnetic environment, the positions of each H-6 from the neighboring rings (geminal and vicinal) were measured in the crystal structure of 30a, and are summarized in Figure 3.19. For comparison, the corresponding data for the magnesium complex 26 are given in Figure 3.20 as an example of a nearly perpendicular species.

While the positions of H 16 and H 46 in 30a relative to the neighboring rings are not as deviated as the "nearly perpendicular" cases of 26, H26 and H36 are greatly affected by the geometry change. These are the protons tilting toward the vicinal neighboring ring (or the vicinal neighboring ring is tilting toward these protons). Apparently, the ring-tilting brings these protons into a more deshielding region of the vicinal neighbor. The distance between the centroid of the vicinal aryl ring and these protons is nearly $5 \AA$, but the deshielding effect may still be effective by ca. +0.4 ppm , according to the Haigh-Mallion ring-current calculation. ${ }^{4}$
ii) Di-(TiBn $\mathbf{T}_{2}$ Complex 35. The ring tilting theory described above is further supported by the spectroscopic features of benzyltitanium complex 35 . Unlike the titanium halide complexes 30/30a and 33/33a, complex 35 does NOT show a highly downfield dd signal near 8 ppm . The most downfield chemical shift of the ligand's aryl rings is $7.16 \mathrm{ppm}\left(\mathrm{C}_{6} \mathrm{D}_{6}\right)$. This shift is most likely due to the relatively small tilting angles of the aryl rings, which are apparently not great enough to bring any H-6 proton into the effective deshielding region of neighboring rings. The phenyl rings of the benzyl groups cannot be the source of deshielding because in solution, they are freely rotating: their net shielding/deshielding effects (if any) presumably average out to nil. The tetraarylethene framework of complex 35 in solution is probably closer to that of the nearly perpendicular tri-magnesium complexes 25-29 rather than other ring-tilted geminal up/down complexes 30-33a.

Figure 3.19. Positions of the $\mathrm{H}-6$ protons in 30a against the geminal(g) or vicinal(v) neighboring ring.

Figure 3.20. Positions of the $\mathrm{H}-6$ protons in 26 against the geminal or vicinal neighboring ring.

In the ${ }^{1} \mathrm{H}$ NMR spectrum of 35 , the two benzyl groups on each Ti atom are clearly differentiated in the ${ }^{1} \mathrm{H}$ NMR spectrum. Compared to the chemical shifts of $\mathrm{TiBn}_{4}$, the methylene signal of one benzyl group is ca. 0.5 ppm downfield, and the other is ca. 0.5 ppm upfield. The benzyl groups must be rotating freely through the $\mathrm{C} 30-\mathrm{Ti}$ or $\mathrm{C} 40-\mathrm{Ti}$ axes, because each pair of methylene protons shows a sharp singlet.

The large chemical shift difference (ca. 1 ppm) between the two benzyl methylene groups can also be attributed to the anisotropic effects of the ligand aryl rings. The positions of the "outward" and "inward" benzylic methylene groups from ligand aryl rings are compared in Figure 3.21. In this comparison, the "inward" methylene group is clearly more in the deshielding region than is the "outward" methylene group. The former is quite far away from the centroid, by ca. 4.7-6.7 $\AA$, but still in the effective deshielding region of some of the aryl groups.

This observation also supports the hypothesis that the position directly above the olefin double bond receives considerable deshielding from all four aryl rings, as was suggested for the centrally coordinated THF in the tri-magnesium complex 25-29 (Figure 3.10) The position of the inward benzylic methylene group relative to the ligand aryl rings in $\mathbf{3 5}$ is similar to the position of the central THF in $\mathbf{2 6}$ described in Figure 3.10.

[^5]Chapter 3 3.1.2. Ti Complexes page 90

Figure 3.21. Positions of the benzylic methylene groups in 35 against the ligand's aryl rings. The double bonds in the aromatic rings are omitted for clarity.

Chapter 3 3.1.2. Ti Complexes page 91
iii) $\mathbf{D i}$-(CpTiCl) Complex 34. The basic ${ }^{1} \mathrm{H}$ NMR spectroscopic features are very similar to those of the geminal up/down di-TiX ${ }_{2}(\text { thf })_{n}$ complexes 30/30a and 33/33a. The four aryl rings are all equivalent, $\alpha$ - and $\beta$-methylene groups in the propyl group are diastereotopic, and the chemical shifts of the aromatic protons are quite similar.

Although the aryl rings of complex 34 are nearly perpendicular to the olefin plane, unlike the rings in 30a and its analogues, the spectrum still shows a highly downfield-shifted aromatic dd signal at $8.21 \mathrm{ppm}(\mathrm{H}-6)$. This signal is even more downfield, by ca. 0.2 to 0.3 ppm , than that of the Cp -free titanium halide complexes. Meanwhile, the $\mathrm{H}-4$ and $\mathrm{H}-5$ signals are also more downfield than those in 30a, but only by ca. 0.08 ppm (H-4) and $0.15 \mathrm{ppm}(\mathrm{H}-5)$.

The source of this deshielding effect on the $\mathrm{H}-6$ protons, however, is not clear. If it is from the ligand aryl rings, they must be tilted in solution phase, in contrast to how they are present in the crystal structure. As discussed earlier for the trinuclear magnesium complex 25, the deshielding effect on the $\mathrm{H}-6$ protons is not significant when the aryl rings are near perpendicular. The Cp rings of the titanium fragment were thus suspected as possible source of anisotropic effects. However, in the crystal structure, the positions of the H16 or H 26 protons relative to the same-side Cp ring (C31~C35) or opposite side Cp (C31'~C35') do not indicate a clear deshielding effect (Figure 3.22). If anything, these $\mathrm{H}-6$ protons seem rather in the shielding region of the opposite Cp ring.

Figure 3.22. Positions of the H16 and H26 protons in complex 34 against the same-side Cp ring ( $\mathrm{C} 31 \sim \mathrm{C} 35$ ) and the opposite Cp ring ( $\mathrm{C} 31^{\prime} \sim \mathrm{C} 35^{\prime}$ ).

### 3.1.2.D. The Collapsed "Sandwich" Complex

i) Synthesis and Structure of 32. The collapsed sandwich-type complex 32 (Figure 3.23) was obtained cleanly by adding one equivalent of $\mathrm{TiCl}_{4}$ to the Na salt of 7 in toluene. The reaction was also reasonably clean without prior deprotonation, but small amounts of impurities were found in the 'H NMR spectrum of the crude product. Using THF as a solvent instead of toluene (with beforehand deprotonation by NaH ) darkened the color of the reaction mixture to almost black, and the product was considerably less pure. The darkened color suggests some reduction of $\mathrm{Ti}(\mathrm{IV})$ to $\mathrm{Ti}(\mathrm{III})$. It is not surprising that ligand 7, a phenolic species, may be oxidized by Ti(IV); the more polar THF may assist the electron transfer. THF may also slow the reaction between $\mathrm{TiCl}_{4}$ and the salt of 7 by coordinating to $\mathrm{TiCl}_{4}$.

Figure 3.23. The sandwich-type complex 32.

This sandwich complex has only one Ti atom per ligand. All of the chlorides from $\mathrm{TiCl}_{4}$ are replaced with aryloxy groups. The reaction gives a $2: 2$ adduct because apparently a single ligand cannot provide a suitable coordination environment to a Ti(IV) atom. The same sandwich-type compound was also reported for the tetrakis( 5 -tert-butyl-2-hydroxyphenyl)ethene ligand by Verkerk (see also Chapter 1, Section 1.0). ${ }^{1}$ Apparently, the ortho-propyl groups are not bulky enough to prevent the collapse of two ligand units in the case of titanium derivatives (in contrast to aluminum complexes, vide infra).

Figure 3.24 provides the crystal structure of $\mathbf{3 2}$ obtained by X-ray crystallographic analysis of the co-crystal of 32 and the $2: 1$ adduct 30a ( $1: 2$ molar
ratio), obtained from one of many crystallization trials of 30a (vide infra). In the molecule of 32, the two ligands are equivalent, as are the Ti atoms. Within each ligand, the four aryl rings are all non-equivalent.

Figure 3.24. X -ray crystallographic structure of 32.
Torsional angles about C3-C4 bond (deg): C61-C3-C4-C81 =-172.7(7), C61-C3-C4$\mathrm{C} 91=8.8(9)$, $\mathrm{C} 71-\mathrm{C} 3-\mathrm{C} 4-\mathrm{C} 81=15.9(11), \mathrm{C} 71-\mathrm{C} 3-\mathrm{C} 4-\mathrm{C} 91=-162.5(6)$. Ring torsion angles (deg): C4-C3-C61-C62 = 84.9(7), C4-C3-C61-C66 $=-90.9(8), \mathrm{C} 4-\mathrm{C} 3-\mathrm{C} 71-$ C72 $=-149.5(7)$, C4-C3-C71-C76 = 39.8(10), C3-C4-C81-C82 $=90.9(8)$, C3-C4-C81-C86 $=-99.1(8), \mathrm{C} 3-\mathrm{C} 4-\mathrm{C} 91-\mathrm{C} 92=-86.2(8), \mathrm{C} 3-\mathrm{C} 4-\mathrm{C} 91-\mathrm{C} 96=98.1(7)$.

The olefin plane is notably distorted, as is seen in the figure and in the torsional angles about the C3-C4 bond of up to $16^{\circ}$. The degree of ring-tilting varies. Among the three rings that are coordinated to the same Ti atom, those diagonally positioned (C61~C66 and C81~C86) are almost perpendicular to the ethene plane, while the other two rings are more tilted, especially the C71~C76 ring. The tilting angle of this ring is ca $50^{\circ}$ from the perpendicular position.
ii) Spectroscopic Features of 32. The four aryl rings of each ligand are also inequivalent in the ${ }^{1} H$ NMR spectrum of 32 , as was expected from the unsymmetrical ligand configuration observed in the crystal structure (Figure 3.25).

Figure 3.25. ${ }^{1} \mathrm{H}$ NMR spectrum of $32\left(\mathrm{C}_{6} \mathrm{D}_{6}\right)$.

There is one highly downfield dd signal ( 8.01 ppm ) of an aromatic proton. Based on the hypothesis that the ring-tilting brings $\mathrm{H}-6$ protons into the deshielding region of a neighboring ring, this downfield signal is assigned either to the H-6 proton of the most tilted aryl ring or that of the neighboring ring that is most affected by the highly tilting ring.
iii) Formation of $\mathbf{3 2}$ in Other Preparations. The X-ray structure of the $2: 2$ adduct 32 was obtained from a co-crystal of 32 and 30 a , as mentioned earlier. The formation of 32 was frequently found in long-term crystallization batches (toluene-pentane medium). The THF-free complex 30 in hydrocarbon solution also produced 32 after a long period of time (along with miscellaneous unidentifiable species). Though considerably minor, the formation of 32 was also noted in the solution of 33a, the bromide analogue of 30a. The formation rate was very slow, but seemingly irreversible. The $1: 2$ adducts $30,30 \mathrm{a}$ and 33a all slowly undergo ligand redistribution to the $2: 2$ adduct 32 and $\mathrm{TiCl}_{4}(\mathrm{thf})_{\mathrm{n}}(\mathrm{n}$ $=0$ or 2 ).

### 3.1.2.E. Isomerization of "Geminal Up/Down" to "Vicinal Up/Down"

Interestingly, the geminal up/down di- $\mathrm{TiCl}_{2}($ thf $)$ complex $\mathbf{3 0 a}$ isomerizes to another isomer in solution within days. When 30 a is kept in solution in $\mathrm{C}_{6} \mathrm{D}_{6}$ at room temperature, a new species, $\mathbf{3 0 b}$, starts to form. The ratio reaches $1: 1$ after several days or longer, or after heating the solution for several hours at $>80^{\circ} \mathrm{C}$ and cooling down to room temperature. The ${ }^{1} \mathrm{H}$ NMR spectroscopy of the mixture of 30a and 30b shows a completely averaged spectrum of the two species at $100^{\circ} \mathrm{C}$.

In one crystallization, crystals of only 30b were obtained. The equilibrium explains why the crystallization of $\mathbf{3 0 a}$ was so difficult: it became a mixture of two compounds. The crystals of $\mathbf{3 0 b}$ were unfortunately not suitable for X -ray analysis, but the $\mathrm{C} / \mathrm{H}$ and Cl analyses matched those expected for 30a. Based on the elemental analysis and the similarity of the NMR spectrum (vide infra), 30b was concluded to be an isomer of $\mathbf{3 0 a}$.

The solution of $\mathbf{3 0 b}$ alone in $\mathrm{C}_{6} \mathrm{D}_{6}$ also became a $1: 1$ mixture of $\mathbf{3 0 a}$ and $\mathbf{3 0 b}$ after several days, unequivocally establishing the equilibrium ratio. The relationship between 30a and 30b is summarized in Scheme 3.9.

$1: 1 \quad\left(25^{\circ} \mathrm{C}\right)$

Scheme 3.9. Relationship between 30a and 30b in solution.

The mysterious new isomer 30b has very similar 'H NMR spectroscopic features to those of $\mathbf{3 0 a}$. All four aryl rings are equivalent, the propyl methylene groups are diastereotopic, and there is a highly downfield-shifted aromatic dd signal ( 7.875 ppm , whereas for $\mathbf{3 0 a}$, the most downfield signal appears at 7.885 ppm ).

Two major spectroscopic differences exist between 30a and 30b. First, while the $\alpha$-methylene protons of the propyl group are both sharp for $\mathbf{3 0 a}$, isomer $\mathbf{3 0 b}$ has one broad (the more downfield one) and one sharp $\alpha$-methylene proton. Second, the relative position of the aromatic protons $\mathrm{H}-5$ and $\mathrm{H}-4$ are switched between $\mathbf{3 0 a}$ and $\mathbf{3 0 b}$. Figure 3.26 presents part of the aromatic regions of ${ }^{1} H$ NMR spectra of 30 a and $\mathbf{3 0 b}$. The chemical shift of the $\mathrm{H}-5$ triplet signal is very similar (only $\Delta 0.01 \mathrm{ppm}$ difference), but the H-4 dd signal is more downfield for $\mathbf{3 0 b}$, compared to that of $\mathbf{3 0 a}$. The difference is ca. $\Delta 0.13 \mathrm{ppm}$.

Interestingly, such isomerization and equilibration were not observed without the presence of THF (i.e., for 30). Apparently, the interconversion between 30a and 30b is assisted by the coordinating THF.

Separately from these isomerization reactions, the crystal structure of a vicinal up/down isomer of the di- $\mathrm{TiCl}_{2}$ (thf) complex, named 31, was serendipitously obtained (Figure 3.27). The crystal was obtained from one of many crystallization attempts for the geminal up/down isomer 30a, from toluene-pentane medium by slow evaporation.

Figure 3.27. X-ray crystallographic structure of 31 the vicinal "up/down" isomer. The label for the aromatic carbon attached to OX is CX2.
Bond length Cl-C2 $=1.339(6) \AA, \mathrm{Til}-\mathrm{ClI}=2.2646(16) \AA$, $\mathrm{Til}-\mathrm{OI}=1.764(3) \AA$, Til-O3 $=1.826(3) \AA$, Til-O5 $=2.177(4) \AA$. Interatomic angle $\mathrm{Ol}-\mathrm{Til}-\mathrm{O} 3=$ $95.13(14)^{\circ}, \mathrm{O} 2-\mathrm{Ti} 2-\mathrm{O} 4=93.71(14)^{\circ}$. Torsional angle through $\mathrm{Cl}-\mathrm{C} 2$ bond: $\mathrm{Cl} 1-$ $\mathrm{C} 1-\mathrm{C} 2-\mathrm{C} 31=6.9(6)^{\circ}, \mathrm{C} 11-\mathrm{C} 1-\mathrm{C} 2-\mathrm{C} 41=174.0(4)^{\circ}, \mathrm{C} 21-\mathrm{Cl}-\mathrm{C} 2-\mathrm{C} 31=-173.8(4)^{\circ}$, $\mathrm{C} 21-\mathrm{Cl}-\mathrm{C} 2-\mathrm{C} 41=5.3(6)^{\circ}$. Ring torsion angle against $\mathrm{Cl}-\mathrm{C} 2$ bond: $\mathrm{C} 2-\mathrm{Cl}-\mathrm{Cl1}-$ $\mathrm{C} 12=52.0(6)^{\circ}, \mathrm{C} 2-\mathrm{Cl}-\mathrm{Cl1}-\mathrm{Cl} 6=-127.2(5)^{\circ}, \mathrm{C} 2-\mathrm{C} 1-\mathrm{C} 21-\mathrm{C} 22=57.4(6)^{\circ}, \mathrm{C} 2-\mathrm{Cl}-$ $\mathrm{C} 21-\mathrm{C} 26=-120.5(5)^{\circ}, \mathrm{C} 1-\mathrm{C} 2-\mathrm{C} 31-\mathrm{C} 32=-110.4(5)^{\circ}, \mathrm{C} 1-\mathrm{C} 2-\mathrm{C} 31-\mathrm{C} 36=70.8(6)^{\circ}$, $\mathrm{C} 1-\mathrm{C} 2-\mathrm{C} 41-\mathrm{C} 42=-106.2(5)^{\circ}, \mathrm{C} 1-\mathrm{C} 2-\mathrm{C} 41-\mathrm{C} 46=71.9(6)^{\circ}$.

In the crystal structure of $\mathbf{3 1}$, each Ti atom takes a trigonal bipyramidal structure, with interatomic angles quite similar to those of the geminal up/down isomer 30a. ${ }^{7}$ To keep the Ti coordination geometry unchanged, the aryl rings are more tilted from the

Chapter 3 3.1.2. Ti Complexes page 99
perpendicular position compared to those of 30a: the ring torsion angles are 20 to $40^{\circ}$ off the perpendicular angle $\left( \pm 90^{\circ}\right)$. The topology of the tilting is again helical. The distortion of the olefin double bond away from coplanarity is roughly 5-7 ${ }^{\circ}$ (by torsional angles about the $\mathrm{Cl}-\mathrm{C} 2$ bond), a level similar to that of 30a.

The situation leading to the formation of crystals of 31 was quite similar to the conditions leading to the formation of crystals of the mysterious equilibrium isomer $\mathbf{3 0 b}$. Moreover, both are isomeric with 30a. However, unfortunately, no direct evidence was obtained to connect 30b and 31. Due to the small amount of the crystals of 31 that were obtained, an insufficient amount was left for ${ }^{1} \mathrm{H}$ NMR spectroscopy after selecting some for X-ray analysis. The mother liquor, after removal of volatiles, showed a ${ }^{1} \mathrm{H}$ NMR spectrum of a mixture containing a symmetrical species with rather broad and (probably) diastereotopic propyl groups, but no highly downfield dd signal in aromatic region. However, it was not certain if these signals belonged to isomer 31.

Nevertheless, it is most logical to conclude that $\mathbf{3 0 b}$ is the vicinal up/down isomer 31. Besides the similarity of the crystallization situation, the crystal structure of $\mathbf{3 1}$ is quite consistent with the spectroscopic features of $\mathbf{3 0 b}$. The major spectroscopic difference of $\mathbf{3 0 b}$ from $\mathbf{3 0 a}$ was, as mentioned earlier, the chemical shift of the $\mathbf{H}-4$ signal. Figure 3.28 compares the crystallographic positions of the aromatic protons ( $\mathrm{H}-4$, $\mathrm{H}-5$ and $\mathrm{H}-6$ ) in 31 and $\mathbf{3 0 a}$ relative to their neighboring aryl rings (geminal or vicinal). The difference between 31 and 30 a is very small for $\mathrm{H}-5$ and $\mathrm{H}-6$, as shown in Figure 3.28-b and -c. In contrast, the difference in H-4 between 31 and 30 a is clear (Figure 3.28-a): some $\mathrm{H}-4$ protons in 31 (circled) are positioned more toward the deshielding region. These are the H14 and H24 protons in 31, affected by the geminal neighboring ring in both cases. This factor explains the further downfield shift of $\mathrm{H}-4$ signal of $\mathbf{3 0 b}$, compared to 30a (Figure 3.27).

(c) H-6 $\uparrow$

(b) H-5 protons
(c) H-6 protons

Chapter 3 3.1.2. Ti Complexes page 101

It is then presumed that the geminal up/down di- $\mathrm{TiCl}_{2}$ (thf) complex 30a and the vicinal analogue $\mathbf{3 0 b} / 31$ exist as an equilibrium mixture at $1: 1$ ratio in hydrocarbon solution (Scheme 3.10).

Scheme 3.10. Presumed interconversion of "geminal up/down" and "vicinal up/down" isomers.

It is interesting to consider the mechanism of the interconversion of 30 a and 31. Breaking a Ti-O bond is required for 30a and 31 to interconvert, although Ti-O bonds are usually quite strong and not easy to break. One possibility is that the interconversion is assisted by THF. As mentioned earlier, the non-THF version 30 did not isomerize to a vicinal analogue.

One proposed mechanism for the interconversion is shown in Scheme 3.11. The first step (a) is a disproportionation between two $(\mathbf{A r O})_{2} \mathrm{TiCl}_{2}($ thf $)$ centers from different molecules (this cannot happen intramolecularly due to the non-interacting ends of the structure). The exchange of THF and " $\mathrm{Cl}^{-}$" is proposed, probably consisting of two steps: first, THF transfers from one metal center to the other, then $\mathrm{Cl}^{-}$transfers from the sterically crowded THF recipient " $(\mathrm{ArO})_{2} \mathrm{TiCl}_{2}(\mathrm{thf})_{2}$ " back to the now unsaturated metal. Thus one titanium becomes titanate " $(\mathrm{ArO})_{2} \mathrm{TiCl}_{3}{ }^{-}$," and the other cationic " $(\mathrm{ArO})_{2} \mathrm{TiCl}(\mathrm{thf})_{2}{ }^{+}$, " in which the positive charge is stabilized by the extra THF coordination, both electronically and sterically.

Chapter 3 3.1.2. Ti Complexes page 102

(a)

Scheme 3.11. Proposed interconversion mechanism of "geminal up/down" and "vicinal up/down" isomers.

Isomerization further proceeds from the titanate I : the electron rich $\mathrm{Ti}^{-}$center undergoes Ti-O cleavage (step b). The "liberated" $\mathrm{ArO}^{-}$then can rotates to the "down" side of the molecule, encountering the other " $(\mathrm{ArO})_{2} \mathrm{TiCl}_{2}(\mathrm{thf})$ " center (step d). Dissociation of THF may be a prerequisite for the aryloxide attack on the Ti center to form a triaryloxy titanate center " $(\mathrm{ArO})_{3} \mathrm{TiCl}_{2}{ }^{-1}$ (step c). Any of the three aryloxy residues can leave and rotate to the "up" side, either reforming the geminal (ArO) $\mathbf{T i C l}_{2}$ or forming the vicinal "( ArO$)_{2} \mathrm{TiCl}_{2}$ " center (step $\mathbf{e}$ ).

The remaining steps achieve the loss of the extra $\mathrm{Cl}^{-}$and gain a sufficient amount of THF to become the final "vicinal up/down" di-\{(ArO) $\left.)_{2} \mathrm{TiCl}_{2}(\mathrm{thf})\right\}$ complex 31. The recovered titanate I can either initiate further isomerization or recombine with the initial cationic species (II) to form the original state. In this proposed mechanism, THF plays an important role in several steps, stabilizing intermediates and associating/dissociating flexibly to provide coordination sites for other donor groups.

This type of isomerization to vicinal analogue is observed for only the di$\mathrm{TiCl}_{2}$ (thf) system 30a and 31. Other geminal up/down species, including the bromo analogue 33a, do not show such chemical behavior. The reason why the isomerization does not occur for the bromo analogue is not clear.

### 3.1.2.F. Dinuclear Cationic Complex from 35?

There are many known examples of alkyltitanium complexes that can be converted into active ethylene polymerization catalysts. Typically, one alkyl group is abstracted by a strongly Lewis acidic reagent to form a cationic titanium species. ${ }^{8}$ Many discrete cationic species have been isolated and structurally well-characterized. ${ }^{8}$ This section describes our attempts to produce a discrete cationic titanium species from the di$\mathrm{TiBn}_{2}$ complex 35 and the promising result with $\mathrm{B}\left(\mathrm{C}_{6} \mathrm{~F}_{5}\right)_{3}$. The ethylene polymerization experiments using 35, however, were not successful (details will be discussed in Chapter 5).

In an attempt to abstract one benzyl group from 35, a $1: 1$ mixture of 35 and $B\left(C_{6} F_{5}\right)_{3}$ was prepared in $\mathrm{C}_{6} \mathrm{D}_{6}$. The ${ }^{1} H$ NMR spectrum was complicated after 15 minutes reaction time, but after longer than one day, the spectrum showed a symmetrical species (36) as a major product. The aromatic region was complicated due to severe peak overlap
(from both the ligand framework and the benzyl groups), but the four propyl groups seemed all equivalent, i.e., all the aryl rings are apparently equivalent. The benzyl methylene singlets were also present in the ratio of $2: 1: 1$.

One possible structure for 36 that meets these spectroscopic features is a dinuclear cationic complex, as shown in Figure 3.29. Attempts to crystallize this product, however, were not successful.

Figure 3.29. One possible structure of 36 , the adduct of 35 and $B\left(C_{6} F_{5}\right)_{3}$.

When THF was used as one component of the crystallization solvents, along with toluene, a layer of clear colorless viscous oil formed after being kept overnight at $-30^{\circ} \mathrm{C}$. This viscous oil, although not confirmed, was presumably polymerized THF, because addition of more THF to this mixture resulted in an increase of the clear oil layer after $>16$ hours. The polymerization of THF must have been catalyzed by 36 , because $B\left(C_{6} F_{5}\right)_{3}$ alone does not polymerize THF, nor does 35 by itself. A combination of $B\left(C_{6} F_{5}\right)_{3}$ and an alkylzirconium complex does not generally polymerize THF either. For example, Mattheis et al. reported the reaction between ( $\left.\eta^{5}: \eta^{\prime}-\mathrm{Cp}^{\prime}\right) \mathrm{ZrMe}_{3}\left(\mathrm{Cp}^{\prime}=\mathrm{C}_{5} \mathrm{H}_{4} \mathrm{CH}_{2} \mathrm{CH}_{2} \mathbf{O M e}\right)$ and $B\left(C_{6} F_{5}\right)_{3}$ in THF, which affords a cationic zirconium complex $\left[\left(\eta^{5} ; \eta^{1}\right.\right.$ $\left.\left.\mathrm{Cp}^{\prime}\right) \mathrm{ZrMe}_{3}(\mathrm{THF})\right]\left[\mathrm{MeB}\left(\mathrm{C}_{6} \mathrm{~F}_{5}\right)_{3}\right]$. Neither of the ions, nor the combination of them, polymerizes THF. ${ }^{9}$

A proposed mechanism for THF polymerization by 36 is given in Scheme 3.12. Polymerization of THF requires a Lewis acid to activate the THF and a nucleophilic reagent to initiate a polymerization. Compound 36 would be not only capable of playing both roles, but also its proposed dinuclear structure would provide an excellent platform for both THF activation and polymer chain growth by alternating the two roles between the two Ti centers.

Scheme 3.12. Proposed mechanism of THF polymerization by 36.

Formation of the dinuclear cationic structure proposed for 36 from the reaction of 35 and $B\left(C_{6} F_{5}\right)_{3}$ requires a conformational change of the ligand framework from "geminal up/down" to "all-up." This change is plausible with the assistance of Lewis acidic $B\left(C_{6} F_{5}\right)_{3}$. A proposed mechanism for this transformation is described in Scheme 3.13.

$+\quad \stackrel{\ominus}{B n-B\left(C_{6} F_{5}\right)_{3}}$

36

Scheme 3.13. Proposed mechanism of formation of 36 from 35 plus $B\left(C_{6} F_{5}\right)_{3}$.

Scheme 3.13 proceeds as follows: the boron reagent can either abstract a benzyl group from 35 (step a) or interact with a phenolato oxygen atom (step b). The latter, with assistance by a catalytic amount of $\left[\mathrm{BnB}\left(\mathrm{C}_{6} \mathrm{~F}_{5}\right)_{3}\right]^{(-)}$formed in step a, allows for cleavage of a Ti-O bond, followed by flipping the affected aryloxytitanium and aryloxyborate groups to the other face of the ligand (steps $\mathbf{c}, \mathbf{d}$ and $\mathbf{e}$ ). The transformation is autocatalytic because once formation of 36 is completed, an equimolar amount of $\left[\mathrm{BnB}\left(\mathrm{C}_{6} \mathrm{~F}_{5}\right)_{3}\right]^{(-)}$is also produced.

Other boron reagents commonly used to activate alkyltitaniums did not give discrete products. Attempted protonolysis by $\left[\mathrm{PhEt}_{2} \mathrm{NH}\right]^{+}\left[\mathrm{Cl}^{-}\right.$in $\mathrm{C}_{6} \mathrm{D}_{6}$ did not proceed cleanly. After more than one day, the 'H NMR spectrum still showed signals from the starting material. The reaction with $\left[\mathrm{PhEt}_{2} \mathrm{NH}\right]^{+}\left[\mathrm{B}\left(\mathrm{C}_{6} \mathrm{~F}_{5}\right)_{4}\right]^{-}$in $\mathrm{C}_{6} \mathrm{D}_{6}$ showed the starting materials and a new compound after 30 minutes at room temperature. After more than one day, a precipitate had formed and the solution showed $\mathrm{PhEt}_{2} \mathrm{~N}$ signals only. The precipitate, obviously the product, unfortunately could not be identified. When the precipitate was redissolved in THF- $\mathrm{d}_{8}$, only broad and complicated signals were observed. One-electron oxidation using either $\left[\mathrm{Ph}_{3} \mathrm{C}\right]^{+}\left[\mathrm{B}\left(\mathrm{C}_{6} \mathrm{~F}_{5}\right)_{4}\right]^{-}$or $\left[\mathrm{Cp}_{2} \mathrm{Fe}\right]^{+}\left[\mathrm{B}\left(\mathrm{C}_{6} \mathrm{~F}_{5}\right)_{4}\right]^{-}$. in toluene did not proceed cleanly, perhaps because of the poor solubility of the reagents. Transferring the mixture to a bomb, adding THF and heating to $100^{\circ} \mathrm{C}$ to promote the reaction, resulted in only broad ${ }^{1} \mathrm{H}$ NMR signals in $\mathrm{C}_{6} \mathrm{D}_{6}$. No tractable product could be isolated from these reaction mixtures.

### 3.1.3. Al Complexes

Reactions of ligand 7 and $\mathrm{R}_{3} \mathrm{Al}(\mathrm{R}=\mathrm{Me}$ or Et$)$ resulted in the formation of discrete tri-aluminum complexes in non-coordinating medium. The analogous reactions with $\mathrm{Et}_{2} \mathrm{AlCl}$ and $\mathrm{EtAlCl}_{2}$ result in indiscrete tetra-aluminum adducts. These products show interesting chemical behavior in a THF medium. This section first describes the products in a non-coordinating medium, then the THF-driven alteration of these products.

### 3.1.3.A. Al Complexes Obtained in Non-Coordinating Medium

i) Adducts of $\mathbf{R}_{3} A l$. Mixing the phenolic ligand 7 and four equivalents of $R_{3} A l$ in toluene gives a non-symmetrical trinuclear aluminum complex 37 ( $\mathrm{R}=\mathrm{Me}$ ) or $38(\mathrm{R}=$ Et) (Scheme 3.14). The fourth equivalent of the reagent is left unreacted in both cases.

37: $R=M e$
38: $R=E t$

Scheme 3.14. Formation of 37 and 38 from 7 and $R_{3} A l$.

The structure of 38 was determined by X -ray crystallography (Figure 3.30). The structure of 37 is considered to be analogous to that of 38 , based on the similarity of the ${ }^{1} \mathrm{H}$ NMR spectroscopic features. In the six-membered ${ }^{\prime} \mathrm{Al}_{3} \mathrm{O}_{3}$ " chair-form crown ring, each aluminum atom holds an axial and an equatorial substituent. The Al 2 and Al 3 atoms hold two ethyl groups, while the All atom has one ethyl group at the axial position, with an ArO group (that is not participating the ${ } \mathrm{Al}_{3} \mathrm{O}_{3}$ " crown ring) at the equatorial position. Overall, three axial and two equatorial ethyl groups are found in the crystal structure.

Chapter 3 3.1.3. Al Complexes page 109

Figure 3.30. X-ray crystallographic structure of the complex 38 with different angle views. The label for the aromatic carbon attached to OX is CX2.
Bond lengths $(\AA):$ All-O1 $=1.699(2)$, All-O2 $=1.863(2)$, All-O3 $=1.855(2)$, All$\mathrm{C} 50=1.943(3), \mathrm{Al} 2-\mathrm{O} 2=1.893(2), \mathrm{Al} 2-\mathrm{O} 4=1.885(2), \mathrm{Al} 2-\mathrm{C} 52=1.955(4), \mathrm{Al} 2-$ $\mathrm{C} 54=1.943(4), \mathrm{Al3-03}=1.887(2), \mathrm{Al3-O4}=1.867(2), \mathrm{Al} 3-\mathrm{C} 56=1.960(3), \mathrm{Al} 3-$ $\mathrm{C} 58=1.954(3)$. Interatomic angles (deg): O1-All-O2 $=109.88(10), \mathrm{O} 1-\mathrm{All}-\mathrm{O} 3=$ 110.24(10), O2-All-O3 = 108.91(9), O3-All-C50 = 107.08(12), O2-Al2-O4 = $92.93(10), \mathrm{O} 3-\mathrm{Al} 3-\mathrm{O} 4=92.36(10), \mathrm{O} 3-\mathrm{Al3}-\mathrm{C} 56=112.02(13)$. Torsional angle of olefin plane (deg): C11-C1-C2-C31 = -9.8(4), C11-C1-C2-C41 = 166.1(3), C21-C1-C2-C31 $=164.1(3), \mathrm{C} 21-\mathrm{Cl}-\mathrm{C} 2-\mathrm{C} 41=-20.0(5)$. Ring torsion angles (deg): $\mathbf{C 2}-\mathrm{C} 1-$ C11-C12 = 93.8(4), C2-C1-C11-C16 = -94.7(4), C2-C1-C21-C22 = $-78.0(4), \mathrm{C} 2-\mathrm{Cl}-$ $\mathrm{C} 21-\mathrm{C} 26=118.0(4), \mathrm{C} 1-\mathrm{C} 2-\mathrm{C} 31-\mathrm{C} 32=-92.4(4), \mathrm{C} 1-\mathrm{C} 2-\mathrm{C} 31-\mathrm{C} 36=87.1(4), \mathrm{C} 1-\mathrm{C} 2-$ $\mathrm{C} 41-\mathrm{C} 42=105.0(4), \mathrm{Cl}-\mathrm{C} 2-\mathrm{C} 41-\mathrm{C} 46=-82.2(4)$.

The olefin plane is distorted, especially at the aryl ring that holds the $\mathbf{O 2}$ atom, as shown in the side view (Figure 3.30, bottom left). This ring is quite lifted in order to bridge between the All and Al 2 atoms and become a part of the " $\mathrm{Al}_{3} \mathrm{O}_{3}$ " crown ring. The aryl ring with the Ol atom is, on the other hand, pushed down from the olefin plane to take the equatorial position of the All atom.

The structure of the trinuclear aluminum complex 38 is not analogous to the $R_{3} \mathrm{Al}$ adducts of parent ligand 2. Verkerk confirmed that a similar reaction with 2 leads to an " $\mathrm{Al}_{4} \mathrm{O}_{4}$ " eight-membered crown ring (Figure 3.31) ${ }^{1}$ as mentioned in Chapter 1. In the case of ligand 7, the ortho-propyl groups evidently limit the coordination site sterically, leaving insufficient room to accommodate four [ $\mathrm{AIEt}_{2}$ ] groups.

Figure 3.31. Verkerk's eight-membered Al crown complex ( $\mathrm{R}=\mathrm{Me}$ or Et ).

As mentioned, complexes 37 and 38 showed common 'H NMR spectroscopic features in $\mathrm{C}_{6} \mathrm{D}_{6}$. The four aryl rings are all different, as expected from the unsymmetrical crystal structure. Three out of five alkyl groups ( Me or Et ) are quite downfield compared to $\mathrm{Me}_{3} \mathrm{Al}\left(-0.36 \mathrm{ppm}\right.$ in $\left.\mathrm{C}_{6} \mathrm{D}_{6}\right)$, and the other two are quite upfield. Figure 3.32 shows the ${ }^{1} \mathrm{H}$ NMR spectrum of the complex 37.

Figure 3.32. 'H NMR spectrum of $37\left(\mathrm{C}_{6} \mathrm{D}_{6}\right)$. The position of free $\mathrm{Me}_{3} \mathrm{Al}(-0.36 \mathrm{ppm})$ is indicated with the dotted line.

The three downfield methyl groups are assigned to the three axial groups, and the two upfield ones to the equatorial methyl groups. Among the metal complexes from ligand 7, the position "above" the olefin plane generally receives a deshielding effect from the aryl rings, while the positions in between neighboring aryl rings are shielded. Although this case is the first example of a complex having an equatorial group between vicinal pair of aryl rings, the effect seems similar to the cases where a substituent is between a geminal pair of aryl rings.

Complex 38 is totally inert toward one equivalent of $\mathrm{TiCl}_{4}$ in $\mathrm{C}_{6} \mathrm{D}_{6}$. The ArO groups are presumably too stable and kinetically protected by the tight bindings to the Al atoms in the crown structure to attack the titanium atom.
ii) Adduct of $\mathrm{Et}_{2} \mathrm{AlCl}$. The reaction of ligand 7 and four equivalents of $\mathrm{Et}_{2} \mathrm{AlCl}$ is not as straightforward as the $\mathrm{R}_{3} \mathrm{Al}$ case. The ${ }^{1} \mathrm{H}$ NMR spectrum of the product(s), labeled C ,

Chapter 3 3.1.3. Al Complexes page 112
in $\mathrm{C}_{6} \mathrm{D}_{6}$ is quite complicated. The elemental analysis of the crystallized product, however, proposes the formula of $\left[\mathrm{C}_{38} \mathrm{H}_{40} \mathrm{O}_{4} \mathrm{Al}_{4} \mathrm{Et}_{4} \mathrm{Cl}_{4}\right]\left(\mathrm{C}_{38} \mathrm{H}_{40} \mathrm{O}_{4}=[7-4 \mathrm{H}]\right)$, consistent with an adduct of 7 and four equivalents of $\mathrm{Et}_{2} \mathrm{AlCl}$. Unlike what occurs in the $\mathrm{R}_{3} \mathrm{Al}$ case, all the four equivalents of the aluminum reagent seem reacted to provide " AlEtCl " fragments to the product. The complicated ${ }^{1} \mathrm{H}$ NMR spectrum in $\mathrm{C}_{6} \mathrm{D}_{6}$ suggests that it is a mixture of many different species.
ii) Adduct of EtAlCl ${ }_{2}$. Unlike the adducts in the previous two cases, the adduct between ligand 7 and four equivalents of $\mathrm{EtAlCl}_{2}$ is insoluble in toluene or other noncoordinating hydrocarbon solvents. The precipitated product, labeled $\mathbf{F}$, gives the $\mathrm{C} / \mathrm{H}$ and Cl elemental analysis results quite close to the calculated values of the fourequivalent adduct $\left[\mathrm{C}_{38} \mathrm{H}_{40} \mathrm{O}_{4} \mathrm{Al}_{4} \mathrm{Cl}_{8}\right]\left(\mathrm{C}_{38} \mathrm{H}_{40} \mathrm{O}_{4}=[7-4 \mathrm{H}]\right)$.

### 3.1.3.B. Chemical Behavior in THF Medium

i) From $\mathrm{Al}_{3} \mathbf{R}_{5}$ Complexes (37/38). No reaction occurs when two equivalents of THF are added to 38 in $\mathrm{C}_{6} \mathrm{D}_{6}$ medium. The aluminum-crown complex is apparently inert to a small amount of THF in solution. The same result was reported by Verkerk for the eightmembered aluminum crown complex of parent ligand $2 .{ }^{\text {. }}$

However, Verkerk reported that dissolving in THF or acetonitrile medium converts the eight-membered crown aluminum complex of parent ligand 2 into the sandwich-type complex, as shown in Scheme 3.15-a (see also Chapter I and reference 1). The collapsed complex has only two equivalents of aluminum and two alkyl groups per ligand. The coordinating solvents apparently "leach out" three equivalents of $\mathrm{R}_{3} \mathrm{Al}$ from each tetranuclear crown system.
(a)

Verkerk's eight-membered crown complex from 2 ( $\mathrm{R}=\mathrm{Me}$ or Et )
(b)

The six-membered crown complex from the ortho-propyl ligand 7

Scheme 3.15. "Collapsing" of the aluminum crown complexes upon leaching out $\mathrm{R}_{3} \mathrm{Al}$ by a coordinating solvent with the proposed structure of A .

Scheme 3.16. Proposed equilibrium between two enantiomers of $\mathbf{A}$.

Dissolving the six-membered crown complex 37 (Scheme 3.15-b) in THF-d $\mathbf{d}_{8}$ results in a new compound, labeled $A$. The ${ }^{\mathbf{1}} \mathrm{H}$ NMR spectrum of the THF- $\mathrm{d}_{8}$ solution shows a completely symmetrical ligand framework (i.e., all aryl rings are equivalent) with diastereotopic propyl methylene protons and two identical methyl groups per ligand. The methyl signal appears at -0.35 ppm , more downfield than that of free $\mathrm{Me}_{3} \mathrm{Al}(-0.94$ ppm in THF- $\mathrm{d}_{8}$ ). The solution also shows one equivalent of liberated $\mathrm{Me}_{3} \mathrm{Al}$ (as fully coordinated by solvent THF- $\mathrm{d}_{8}$ ).

Although X-ray crystallography or other decisive structural determination is unavailable, the structure of $\mathbf{A}$ is proposed as shown in Scheme $\mathbf{3 . 1 5 - b}$. The dinuclear aluminum structure is consistent with the 'H NMR spectroscopic features: the stoichiometry of methyl groups and the deshielding effect caused by the axial methyl positions. To meet the ligand symmetry requirement, the equilibration of two enantiomers is proposed (Scheme 3.16). The exchange must be fast to make all the aryl rings equivalent. Note that the connectivity of the bottom-right Al atom in 37 (in Scheme 3.16) is retained in the structure of $A$. The ${ }^{\prime} H$ NMR spectrum hardly changes when the temperature is lowered to $-60^{\circ} \mathrm{C}$ : the equilibration is still fast for the NMR time-scale at this temperature.
ii) From $\mathrm{Al}_{4} \mathrm{Et}_{4} \mathrm{Cl}_{4}$ Adduct C . The THF-d solution of C , the $\mathrm{Al}_{4} \mathrm{Et}_{4} \mathrm{Cl}_{4}$ adduct or adduct mixture also shows a new compound, labeled $\mathbf{D}$, immediately after preparation of the solution. This product $D$ has very similar spectroscopic features to those of the previously discussed $\mathbf{A}$. The ligand framework is all-symmetric with two identical ethyl groups, which are downfield-shifted. The chemical shifts of the ligand protons are very similar to those of $\mathbf{A}$. The solution also shows two equivalents of liberated $\mathrm{EtAlCl}_{2}$. It is considered that the structure of $\mathbf{D}$ is analogous to that of $\mathbf{A}$, differing only by the alkyl group (Et vs. Me).

The same mixture, however, showed a completely different spectrum after remaing in THF- $\mathrm{d}_{8}$ overnight. The resulting 'H NMR spectrum in THF- $\mathrm{d}_{8}$ was not simple, possibly showing a mixture. The resulting species or mixture is labeled $\mathbf{E}$. Scheme 3.17 tentatively summarizes the alteration of $\mathbf{C}$ to $\mathbf{D}$, and then to $\mathbf{E}$.

The product E , the result of prolonged exposure to THF medium, was separately prepared by dissolving $\mathbf{C}$ in normal THF and stirring overnight. After removal of volatiles, the $\mathrm{C}_{6} \mathrm{D}_{6}$ solution of the resulting product $(\mathrm{E})$ showed a ligand framework with $\sigma$-symmetry with one downfield THF molecule and two different ethyl groups: one
upfield and one in the normal region; also observed were liberated aluminum reagents. The THF- $\mathrm{d}_{8}$ solution of the same product showed the same ${ }^{1} \mathrm{H}$ NMR spectrum that matched the first THF-d dissolution experiment after being kept overnight.

E
Scheme 3.17. The THF-driven transformation of $\mathbf{C}$ into $\mathbf{D}$ and $\mathbf{E}$.

Figure 3.33 provides the proposed structure of E , which meets the ${ }^{\mathbf{\prime}} \mathrm{H}$ NMR spectroscopic features in $\mathrm{C}_{6} \mathrm{D}_{6}$. The ligand framework in the proposed structure can be $\sigma$ symmetric if the full and dative $\mathrm{Al}-\mathrm{O}$ bonds between the central and terminal Al atoms exchange rapidly in solution. The two ethyl groups, one upfield and one in normal region, are assigned to the equatorial and axial ethyl groups on the terminal Al atom. A similar terminal " $\mathrm{AlEt}_{2}$ " fragment was found in other crystallographically characterized complexes 41 and 42 (vide infra, section 3.2.1.A). Finally, the THF coordinated on the central Al atom can account for the highly downfield-shifted THF signals.

The different spectroscopic appearance of $E$ when dissolved in THF- $d_{8}$ is partly explained by the desymmetrization induced by excess THF- $\mathrm{d}_{8}$. Unlike what occurs in $\mathrm{C}_{6} \mathrm{D}_{6}$, the presence of excess THF- $\mathrm{d}_{8}$ causes both central and terminal Al atoms to coordinate THF- $\mathrm{d}_{8}$, breaking the dative Al-O bonds completely: this process makes the
ligand framework unsymmetrical (Figure 3.33-b). The spectrum, however, is more complicated than was expected for a single unsymmetrical species. The reversible transformation from monomeric to dimeric species upon further alkyl reagent abstraction is suggested in Figure 3.33-b, as one possible explanation to account for the complicated ${ }^{1} H$ NMR spectrum in THF-d ${ }_{8}$.

Figure 3.33. Proposed structure of $E$ and different appearance in (a) $C_{6} D_{6}$ and (b) THF-d ${ }_{8}$.

Crystallization of $\mathbf{E}$ was, unfortunately, unsuccessful. It tends to oil out from hydrocarbon medium (e.g., pentane). However, the similarly-obtained complex 39 gave a crystal structure that supports the suggested structure of $\mathbf{E}$ (vide infra).

It is interesting that the dinuclear diethyl complex $\mathbf{D}$ further disproportionates to the pseudo- $\sigma$-symmetry species $\mathbf{E}$ in a THF medium, while the dimethyl complex $\mathbf{A}$ remains unchanged. The disproportionation of $D$ is probably promoted by the larger size of the ethyl group. If the suggested structures of $A$ and $D$ are correct, the two alkyl groups are both at the axial positions on an $\mathrm{Al}_{2} \mathrm{O}_{2}$ four-membered ring, probably close enough to each other to experience repulsive van der Waals interactions. Having larger ethyl groups on these positions makes $\mathbf{D}$ less stable.

The conversion of $\mathbf{D}$ to $\mathbf{E}$ upon prolonged exposure to THF- $\mathbf{d}_{8}$ is, in other words, the intramolecular disproportionation of two "( ArO$)_{2} \mathrm{EtAl}$ " units into "( ArO$)_{3} \mathrm{Al}($ thf $)$ " and "( ArO$) \mathrm{Et}_{2} \mathrm{Al}($ thf)" units. The above-mentioned steric repulsion is probably the driving force.

In summary, we have observed a stepwise alteration from the initial fourequivalent $\mathrm{Et}_{2} \mathrm{AlCl}$ adduct $\mathbf{C}$ to $\mathbf{D}$, and then to $\mathbf{E}$. The transformation of $\mathbf{C}$ to $\mathbf{D}$ is driven by aluminum scavenging by the coordinating solvent, and $\mathbf{D}$ to $\mathbf{E}$ is an intramolecular disproportionation of the aluminum centers.
iii) From $\mathbf{A l}_{4} \mathbf{C l}_{8}$ Adduct $\mathbf{F}$. The THF-driven conversion of $\mathbf{F}$, the $\mathrm{Al}_{4} \mathrm{Cl}_{8}$ adduct, partly parallels that of the ethyl-group containing analogue $\mathbf{C}$. Because no ethyl groups are in $\mathbf{F}$, the information provided by ${ }^{1} \mathrm{H}$ NMR studies was more limited. Nevertheless, the symmetry change in the ligand framework was often quite informative, allowing for a reasonable analogy to be made the previously discussed aluminum complexes.

The toluene-insoluble product $F$ is well-soluble in THF- $d_{8}$. Immediately after the solution was prepared, the ${ }^{\mathrm{I}} \mathrm{H}$ NMR spectrum showed two species: one a $\sigma$-symmetry compound $G$, with all sharp signals; the other $H$, consisting of rather broad signals. The ratio of $\mathbf{G}: \mathbf{H}$ was ca. 1.5~2: 1, made imprecise by the broadness and overlapping of signals.

After being kept overnight in THF- $\mathrm{d}_{8}$, the ${ }^{1} \mathrm{H}$ NMR spectra no longer showed either $\mathbf{G}$ or $\mathbf{H}$, but gives a complicated spectrum, seemingly a mixture of at least two compounds. The product after prolonged exposure to THF- $\mathrm{d}_{8}$ is labeled 39. The same product 39 obtained from separate reaction ${ }^{c}$ showed the same complicated ${ }^{1} \mathrm{H}$ NMR

[^6]Chapter 3 3.1.3. Al Complexes page 118
spectrum in THF- $\mathrm{d}_{8}$, but showed a $\sigma$-symmetry ligand framework in $\mathrm{C}_{6} \mathrm{D}_{6}$, accompanied by one deshielded coordinating THF molecule ( $\alpha$ proton signal at 4.25 ppm ). The solidstate structure was obtained as shown in Figure 3.34 (for detailed data, see Appendix A12).

Figure 3.34. X-ray crystallographic structure of 39.

The crystal structure of 39 provided very useful information relevant to the THFdriven alteration of aluminum complexes derived from ligand 7. This information further supports the proposed structure of the similarly-produced diethyl analogue $\mathbf{E}$ (Figure 3.33) described in the previous section. The resemblance between the ${ }^{1} \mathrm{H}$ NMR spectroscopic features of 39 and the diethyl analog $E$ in $\mathrm{C}_{6} \mathrm{D}_{6}$ also complements the analogy. Although the crystal structure of 39 is not symmetrical, it may equilibrate the $\mathrm{Al}-\mathrm{O}$ bonds between the central and the terminal Al atoms in solution, becoming pseudo-$\sigma$-symmetrical, as observed in the ${ }^{\prime} H$ NMR spectrum in $C_{6} D_{6}$.

Scheme 3.18 summarizes all the THF-driven aluminum abstraction chemistry of 37, $\mathbf{C}$ and $\mathbf{F}$ with proposed structures.

Scheme 3.18. Summary of the aluminum complexes and the chemical behavior in THF medium.

Chapter 3 3.1.3. Al Complexes page 120

The structure of $\mathbf{G}$, the result of brief THF- $\mathrm{d}_{8}$ exposure of $\mathbf{F}$, is suggested to be the same as 39 , to meet the $\sigma$-symmetry requirement. This assignment is based on the hypothesis that either $\mathbf{F}$ does not go through a symmetrical intermediate prior to intramolecular disproportionation (as observed for 37 or $\mathbf{C}$ ), or it does so too quickly to be observed spectroscopically. To meet this hypothesis, the coordination of THF to desymmetrize $\mathbf{G}$ must be slow, although it may be unusual in the presence of excess THF-d . However, after being kept in THF-d $_{8}$ overnight, the desymmetrization (and possible further conversion as also suggested for $\mathbf{E}$ ) is complete in THF. Upon removal of THF and re-dissolution in $\mathrm{C}_{6} \mathrm{D}_{6}$, the complex reverts to the $\sigma$-symmetric 39.

The identity of $\mathbf{H}$, which showed broad signals observed together with the complex assigned as $\mathbf{G}$, remains unclear. Possibly, it is an intermediate stage between the all-symmetric stage (analogous to $\mathbf{D}$ or $\mathbf{A}$ ) and $\mathbf{G}$, or between $\mathbf{G}$ and the desymmetrized stage (39) by a second coordination of THF to the terminal Al atom.

### 3.1.3.C. Conclusion of the Aluminum Chemistry of Ligand 7

The aluminum complexes derived from ligand 7 showed various connectivity patterns, depending on the degree of exposure to excess THF. The reactivity toward THF is clearly affected by the different groups bonded to aluminum (methyl, ethyl, ethyl/chloro or chloro).

### 3.1.4. Na Complex

Although sodium is not a metal typically used for heterogeneous Ziegler-Natta catalysts, the sodium salts of various phenoxide ligands were prepared and studied as precatalysts for ethene polymerization, mainly to compare with the corresponding magnesium salts (Chapter 5). In this section, the solid-state structure of the sodium salt of ligand 7 (40) is examined to compare the coordination tendency of this " +1 " cation with that of previously discussed titanium(IV), aluminum(III) or magnesium(II) ions.

Chapter 3 3.1.3. Al Complexes page 121

The sodium salt 40 was prepared by adding four equivalents of NaH to the phenolic ligand 7 in toluene. The resulting solution was slightly cloudy and pale yellowgreen. After filtration and concentration of the solution, crystallization from toluenehexane gave light yellow-green crystals. The elemental analysis ( $\mathrm{C} / \mathrm{H}$ ) gave the best match to the formula of $\mathrm{C}_{38} \mathrm{H}_{40} \mathrm{O}_{4} \bullet \mathrm{Na}_{4} \bullet$ (toluene $)_{1 / 2}\left(\mathrm{C}_{38} \mathrm{H}_{40} \mathrm{O}_{4}=[7-4 \mathrm{H}]\right)$.

The X-ray crystal structure of complex 40 revealed the trimeric structure in the solid state (Figure 3.35). The $\mathrm{Na} / \mathrm{O}$ cluster consists of a " $\mathrm{Na}_{6} \mathrm{O}_{6}$ " inner core and three " $\mathrm{Na}_{2} \mathrm{O}_{2}$ " outer subunits. Each sodium atom in the inner core assumes a trigonal pyramidal coordination geometry. The inner core consists of two nearly eclipsed " $\mathrm{Na}_{3} \mathrm{O}_{3}$ " hexagons.

Each sodium atom in the outer subunits also has pseudo-trigonal bipyramidal geometry, ${ }^{d}$ receiving $\eta^{6}$-coordination from one aryl ring at one of the equatorial positions. The second equatorial position and the axial position are occupied by phenolato oxygens. The remaining equatorial ligand is not quite resolved. Some electron density was found at the position, but it was not possible to identify this molecule due to the weak data set (4444 observed data out of 13097 total unique data; $R_{1}=15.7 \%$ ). This molecule is suspected, however, to be a toluene molecule, since it is the only possibility included in the crystal of $\mathbf{4 0}$ available for coordination.

In each ligand unit (Figure 3.36), two diagonal oxygen atoms are used in the inner core, and the other two in the outer subunits. The aryl rings attached to the oxygen atoms constructing the inner core are the same rings that are used for $\eta^{6}$-coordination to the outer-sodium atoms.

The ${ }^{1} H$ NMR spectrum of 40 in $\mathrm{C}_{6} \mathrm{D}_{6}$ shows broad peaks at room temperature: three in the aromatic region and three in the propyl region. The integrals are consistent with the ligand framework. The broadness suggests that the trimer structure of the sodium salt 40 is not retained in solution phase. Upon dissolution, the solvent toluene or benzene molecules must aid in the dissociation of the trimer into monomers by occupying the vacant coordination sites, and/or assisting a different kind of association of monomers.

[^7]Chapter 3 3.1.4. Na Complex page 122

Chapter 3 3.1.4. Na Complex page 123

The solid-state structure and the solution behavior of the $\mathrm{Na}(\mathrm{I})$ complex 40 showed the compound's relatively weak tendency to form a monomeric discrete complex, compared to the previously discussed $\mathbf{M g}$ (II), Al (III), and $\mathrm{Ti}(\mathrm{IV})$ cases. The critical factor is the number of metal centers per ligand. Each ligand must hold four $\mathrm{Na}(\mathrm{I})$ centers, each of which has certain coordination demands. This leads to intermolecular interactions because a single ligand cannot provide sufficient Lewis bases to satisfy all four metal centers, even with the $\pi$-electrons of the aryl rings.

### 3.2. Hetero-polymetallic Complexes

Because it is believed that the active sites of classic heterogeneous Ziegler-Natta catalysts are not monometallic but consist of titanium (IV or III) bridging to other metals such as aluminum (III) and/or magnesium (II) atoms (Chapter 2), the construction of characterizable hetero-polymetallic complexes was a major goal of this research, as potential models for such heterogeneous systems. As discussed, ligand 7 was found to give various polymetallic complexes consisting of one kind of metal atom. The next goal was to build hetero-polymetallic species on the ligand system.

Several $\mathrm{Mg} / \mathrm{Al}, \mathrm{Mg} / \mathrm{Ti}$ and $\mathrm{Al} / \mathrm{Ti}$ hetero-polymetallic complexes were obtained and structurally characterized. All of them were prepared using the tri-magnesium complex 25 as a starting material. The essential feature of $\mathbf{2 5}$ that made these syntheses possible is that it has formally two kinds of magnesium phenoxides (Figure 3.37). The central magnesium is a magnesium diaryloxide, and the terminal ones are aryloxymagnesium chlorides. The nucleophilicity of all the four aryloxides is equivalent due to the dative coordination, but the magnesium metals' lability toward replacement by other metals is different. Apparently, the terminal magnesium atom is more labile to replacement by other metals than is the central magnesium atom.

The general strategy for building a hetero-polymetallic complex from 25 was, therefore, the addition of one or two equivalents of $R_{m} M X_{n}$ ( $m$ and $n$ are integers; $R$ is any alkyl group; $m+n=$ the metal's oxidation number; $M$ is a metal other than magnesium; and X is halide or any leaving group). To avoid overreaction, i.e., complete replacement of all magnesium atoms, the number of $X$ groups on the reagent ( $n$ ) must be limited. In relation to the composition of classic heterogeneous Ziegler-Natta catalysts, the metal in our inyestigation (M) is limited to $\mathrm{Al}(\mathrm{III})$ and $\mathrm{Ti}(\mathrm{IV})$.

Chapter 3 3.1.4. Na Complex page 124

Figure 3.37. "Formal" description of 25.

The balance between the nucleophilicity of the magnesium aryloxides and reactivity of metal chloride reagent is important, especially when an excess number of potential leaving groups $\mathbf{X}$ are present on the reagent. To replace the terminal magnesium (chloride) of $\mathbf{2 5}$ while keeping the central magnesium atom on the ligand, the metal halide should be reactive enough for the former but inert toward the latter. There are not many options, however, because the reactivity of metal halides toward an aryloxymagnesium is largely determined by the metal, which we limited to titanium and aluminum only. Titanium halides were found to be so reactive that no excess halide could be on the reagent. Aluminum reagents, on the other hand, showed a great selectivity toward the terminal aryloxymagnesium centers.

In the following sections, the syntheses and structural/spectroscopic features of $\mathrm{Mg} / \mathrm{Al}, \mathrm{Mg} / \mathrm{Ti}$, and $\mathrm{Al} / \mathrm{Ti}$ hetero-polymetallic complexes will be discussed. Most of these complexes were evaluated for ethylene polymerization activity; these results will be discussed in Chapter 5.

### 3.2.1. Mg/Al Complexes

Addition of one or two equivalents of $\mathrm{Et}_{2} \mathrm{AlCl}$ or $\mathrm{EtAlCl}_{2}$ to the tri-magnesium complex 25 resulted in the formation of discrete $\mathbf{M g} / \mathrm{Al}$ hetero-polymetallic complexes. The difference in lability between the central and terminal $\mathbf{M g}$ atoms is exploited in this reactivity.

### 3.2.1.A. Addition of $\mathrm{Et}_{2} \mathrm{AlCl}$ to $\mathbf{2 5}$

The addition of one equivalent of $\mathrm{Et}_{2} \mathrm{AlCl}$ to 25 in toluene successfully produced the Al-Mg-Mg complex 41 within 3 hours (Scheme 3.19-a). The clean formation of 41 in these conditions demonstrates the large reactivity difference between the terminal and central magnesium atoms in $\mathbf{2 5}$. Furthermore, the lability of the first and second terminal magnesium atoms is also apparently quite different, because no overreaction product (i.e., formation of 42) was observed.

(a)
(b)

Scheme 3.19. The preparation of (a) the Al-Mg-Mg complex 41 and (b) the Al$\mathbf{M g}$-Al complex 42.

The difference between the first and the second replacement of the terminal $\mathbf{~ M g}$ atoms was further confirmed when two equivalents of $\mathrm{Et}_{2} \mathrm{AlCl}$ were added to 25 in toluene. When the reaction was worked-up within 15 minutes, ${ }^{1} \mathrm{H}$ NMR spectroscopy of the product showed a mixture of 41 and 42 in a $2.8: 1$ ratio. When a reaction under the same conditions was continued for 3 days, the ratio was reversed to $1: 2.5$, but the reaction remained incomplete. This observation suggests that the second replacement is not only slow but also never goes to completion with only two equivalents of the reagent. The addition of four equivalents of $\mathrm{Et}_{2} \mathrm{AlCl}$ was required to obtain the $\mathrm{Al}-\mathrm{Mg}-\mathrm{Al}$ complex 42 exclusively (Scheme 3.19-b). The reason for the slow second addition is probably that the second equivalent of $\mathrm{Et}_{2} \mathrm{AlCl}$ is deactivated by the byproduct $\mathrm{MgCl}_{2}($ thf $)$ formed in the first replacement, by either THF or chloride transfer to the Al atom. If this conclusion were true, four equivalents of the reagent would be required to complete the second aluminum addition to compensate for the consumption of reagent by the $\mathrm{MgCl}_{\mathbf{2}}(\mathbf{t h f})$, of which two equivalents would be formed.

When four equivalents of $\mathrm{Et}_{2} \mathrm{AlCl}$ were used, the formation of 42 was indeed complete within a day. An NMR-tube reaction under the same conditions in $\mathrm{C}_{6} \mathrm{D}_{6}$ confirmed that no 41 remained after 5 hours of reaction, but instead of clean 42, a mixture of 42 and other unknown species was observed. The same reaction mixture, after 28 hours, showed $\mathbf{4 2}$ exclusively. The identity of the intermediate species was not clear.

The structures of 41 and 42 were confirmed by X-ray crystallography, as shown in Figures 3.38 and 3.39 (with selected data in Table 3.4, for details see Appendices A13 and A-14). Both structures are quite similar to the starting material 25: tri-nuclear connectivity on the "all-up" ligand platform, aryl rings nearly perpendicular to the olefin plane, and even the positioning of the four propyl groups in the crystal.

The distance of the metal atoms from the $\mathbf{O}_{4}$ plane is considerably different for a terminal " $\mathrm{MgCl}\left(\mathrm{thf}\right.$ )" group (in 25 and 41 ) and a terminal " $\mathrm{AlEt}_{2}$ " group (in 41 and 42): the former is more "uplifted" than the latter. The side view projections of 25,41 and 42 reveal the degree of uplifting (Figure 3.40). Table 3.5 presents the distance of each metal atom from the $\mathrm{O}_{4}$ plane. The degree of uplifting most likely differs because of the different equatorial groups: the THF molecule on a terminal $\mathbf{M g}$ atom requires more space than the ethyl group does on the Al atoms.

Figure 3.40. Comparison of the side views of $\mathbf{2 5}, 41$ and 42 and selected torsion angles.

The symmetry and composition of the Al-Mg-Mg complex 41 and the $\mathrm{Al}-\mathrm{Mg}-\mathrm{Al}$ complex 42 are all consistent with the ${ }^{1} H$ NMR spectroscopic features $\left(C_{6} D_{6}\right)$. The basic features, such as the diastereotopicity of the propyl groups and the relative order of chemical shifts of the aromatic protons, are all analogous to those of the tri-magnesium complex 25.

The axial and equatorial ethyl groups are clearly differentiated, as are the central and terminal THF molecules, based on the assignments for the tri-magnesium complex 25. Table 3.6 summarizes the chemical shifts of the THF and ethyl groups in 41 and 42 (with the data of $\mathbf{2 5}$ as a reference). These chemical shifts clearly indicate the positions of these groups (i.e., central/terminal or axial/equatorial).

Table 3.6. Chemical shifts ( ${ }^{1} \mathrm{H}$ NMR) of the coordinating THF and ethyl groups on $\mathbf{M g}$ or Al atoms in complexes 41 and 42. Chemical shifts of 25, free THF and free $\mathrm{Et}_{3} \mathrm{Al}$ are given for comparison.

The $\alpha$ - and $\beta$-methylene protons of the central THF of complex 41 are each quite split, by $\sim 0.4 \mathrm{ppm}$, reflecting the different terminal groups. These peaks are broadened, possibly from slow rotation of the central THF molecule. Although the THF should mainly remain at the sterically least-demanding angle, as in the crystal structure (i.e., C51-O5-C54 plane twisted by $90^{\circ}$ from the $\mathrm{C}=\mathrm{C}$ bond), the space between the terminal " $\mathrm{MgCl}(\mathrm{thf})$ " or " $\mathrm{AlEt}_{2}$ " groups seems wide enough to allow for the rotation.

The central THF molecule in the Al-Mg-Al complex 42 is still downfield-shifted $\left(\alpha-\mathrm{CH}_{2}: 4.37 \mathrm{ppm}\right)$, but not as downfield as that in $\mathbf{2 5}\left(\alpha-\mathrm{CH}_{2}: 4.92 \mathrm{ppm}\right)$. This difference is probably because the terminal " $\mathrm{AlEt}_{2}$ " groups are not as electron-withdrawing as the " $\mathrm{MgCl}($ thf $)$ " groups. The central THF molecule of $\mathbf{4 1}$ has the chemical shifts ${ }^{\mathrm{e}}$ inbetween those determined for 25 and 42.

[^8]Chapter 3 3.2.1. Mg/Al Complexes page 132

The highly upfield ethyl group(s) in 41 or 42 are assigned to the equatorial ethyl group(s), because they are in the shielding region of the neighboring aryl rings. The other set of ethyl signals appears in the normal region, and is therefore assigned to the axial ethyl group(s). Apparently, the anisotropic effects on these positions exerted by the ligand aryl rings are minimal.

### 3.2.1.B. Addition of EtAlCl ${ }_{2}$ to 25

The addition of $\mathrm{EtAlCl}_{2}$, instead of $\mathrm{Et}_{2} \mathrm{AlCl}$, to 25 resulted in the analogous products 43 and 44 (Scheme 3.20). However, the one-equivalent adduct 43 did not form cleanly, even when one equivalent of the reagent was used. In an NMR-tube reaction, the 1:1 mixture of 25 and $\mathrm{EtAlCl}_{2}$ produced a mixture of $25: 43: 44$ one day after the solution was prepared. Apparently, the first and the second replacements of the terminal $\mathbf{M g}$ units are less differentiated for the more electrophilic reagent.

43

44

(b)

Scheme 3.20. Formation of 43 and 44.

The use of at least four equivalents of $\mathrm{EtAlCl}_{2}$ was required to produce the double substitution product 44 free from any incomplete adduct 43 . This finding is analogous to that in the case of $\mathbf{4 2}$, as discussed in the previous section. The scale-up of this reaction
and all attempts at crystallization, however, resulted in the formation of less pure material for unknown reasons. Complexes 43 and 44, therefore, were not isolated.

The structures of 43 and 44 were identified from ${ }^{1} \mathrm{H}$ NMR spectroscopy alone. The ethyl groups in the terminal " AlEtCl " units were determined to be equatorially positioned, based on the upfield chemical shift of the ethyl signals. Other spectroscopic features were similar to those observed for 41 and 42.

### 3.2.2. Mg/Ti Complex

Our first attempt to produce a $\mathrm{Mg} / \mathrm{Ti}$ complex was by mixing the tri-magnesium complex 25 with one or two equivalents of $\mathrm{TiCl}_{4}$, but these reactions failed. As discussed earlier, in Section 3.1.2.A., titanium-only complexes (such as 32 and 30a) were formed, leaving no magnesium in the complex. Aryloxymagnesium groups are simply so nucleophilic toward titanium chlorides that the substitution does not end until no $\mathrm{Ti}-\mathrm{Cl}$ or no aryloxymagnesium moieties remain in the system. To leave a magnesium atom in the ligand framework, the number of chlorides (leaving groups) on the titanium reagent must be restricted.

Tribenzyltitanium chloride ( $\mathrm{Bn}_{3} \mathrm{TiCl}$ ) was therefore selected as a titanium reagent with a minimal number of leaving groups. Syntheses and physical properties of $\mathrm{Bn}_{4} \mathrm{Ti}$, $\mathrm{Bn}_{4} \mathrm{Zr}$ and mixed halogen/alkoxy derivatives were reported several decades ago by Zucchini and others. ${ }^{10}$ Because thermal instability in solution was reported for $\mathrm{Bn}_{3} \mathrm{TiCl}$, it was prepared in situ using the conditions reported by Ivanova et al. They reported that a 1 : 1 mixture of $\mathrm{TiCl}_{4}$ and $\mathrm{TiBn}_{4}$ in toluene at $-50^{\circ} \mathrm{C}$ results in a mixture of $\mathrm{Bn}_{3} \mathrm{TiCl}, \beta$ $\mathrm{TiCl}_{3}$ (precipitate) and bibenzyl (Eq. 3.1). ${ }^{11}$ Apparently, the reaction mixture does not produce the conproportionation product $\mathrm{Bn}_{2} \mathrm{TiCl}_{2}$, but instead leads to irreversible reduction of titanium(IV) to titanium (III).

$$
\begin{equation*}
\mathrm{TiCl}_{4}+\mathrm{TiBn}_{4} \rightarrow \mathrm{Bn}_{3} \mathrm{TiCl}+\beta-\mathrm{TiCl}_{3} \downarrow+1 / 2 \mathrm{Bn}_{2} \tag{Eq.3.1}
\end{equation*}
$$

Assuming that the precipitated $\beta-\mathrm{TiCl}_{3}$ is innocent in solution phase reactions, we used this method to produce $\mathrm{Bn}_{3} \mathrm{TiCl}$ in situ. After mixing $\mathrm{TiBn}_{4}$ and $\mathrm{TiCl}_{4}$ for 10 to 20 minutes in toluene at $-50{ }^{\circ} \mathrm{C}$, the toluene solution of $25\left(\mathrm{Bn}_{3} \mathrm{TiCl} ": 25=1: 1\right)$ was
slowly added to the reagent mixture. After work-up and crystallization, a clean $\mathbf{M g} / \mathrm{Ti}$ dinuclear complex 45 (Figure 3.41) was obtained in a 45\% yield. X-ray crystallography of the compound established the dimeric structure (for details see Appendix A-15).

Figure 3.41. X-ray crystallographic structure of 45.

The structure of 45 was not what had been anticipated from the reaction. The titanium atom was expected to lose a chloride and gain aryloxide(s), but the three benzyl groups were not expected to be replaced. However, one equivalent of " $\mathrm{Bn}_{2} \mathrm{Mg}(\mathrm{thf})$ " apparently leaves the system, resulting in 45.

Nevertheless, 45 is the first and the only $\mathbf{M g} / \mathrm{Ti}$ hetero-polymetallic complex obtained for ligand system 7 or any other of the preorganized ligands developed and used in this research. Unfortunately, complex 45 does not polymerize ethene upon standard activation (Chapter 5).

Several combinations of stoichiometry and different benzyltitanium chlorides $\mathrm{Bn}_{\mathrm{x}} \mathrm{TiX}_{4 \mathrm{x}}$ were tested, but none but the above-mentioned case was successful. The examined cases are summarized in Table 3.7. The condition that led to the preparation of 45 is entry 1. In entries 5 and 6, the trinuclear dibenzyl magnesium complex 29 (see section 4.1.1.B) was used as a starting material. The intention was either to exchange the benzyl groups in 29 with the chlorides of $\mathrm{TiCl}_{4}$ in situ to generate $\mathrm{Bn}_{2} \mathbf{T i C l}_{2}$. The product mixture from entry 6 contained sharp signals on ${ }^{1} \mathrm{H}$ NMR spectroscopy, but it was a mixture. The broad signals observed in most other cases could be due to the reduced $\mathrm{Ti}($ III) species.

a. $2 \mathrm{TiCl}_{4}+\mathrm{TiBn}_{4} \rightarrow \mathrm{Bn}_{2} \mathrm{TiCl}_{2}+2 \beta-\mathrm{TiCl}_{3} \downarrow+\mathrm{Bn}_{2}$
(Eq. 4.2) ${ }^{11}$
b. $\mathrm{TiCl}_{4}+3 \mathrm{TiBn}_{4} \rightarrow 2 \mathrm{Bn}_{3} \mathrm{TiBr}^{2}$
(Eq. 4.3) ${ }^{12}$
c. The complex 29 is the trinuclear magnesium complex with two benzyl groups on the terminal magnesium atoms. The formula of 29 is only approximate, thus the (A) : (B) ratio is not very precise.
d. Unless otherwise stated, the reagent was prepared in situ at $-50^{\circ} \mathrm{C}$ in toluene medium and the starting material was added at this temperature.

### 3.2.3. AL/Ti Complex

Preliminary attempts to construct $\mathrm{Al} / \mathrm{Mg} / \mathrm{Ti}$ or $\mathrm{Al} / \mathrm{Ti}$ hetero-polymetallic complexes were made by adding $\mathrm{TiCl}_{4}$ to the $\mathrm{Al} / \mathrm{Mg}$ complexes 41 and 42 . Replacing one Mg atom in the $\mathrm{Al}-\mathrm{Mg}-\mathrm{Mg}$ complex 41 with one Ti atom was anticipated to produce a $\mathrm{Al} / \mathrm{Mg} / \mathrm{Ti}$ system. If the second Mg atom is too easily replaced, the reaction could still produce an $\mathrm{Al} / \mathrm{Ti}$ hetero-polymetallic species. Replacing an Mg atom in the $\mathrm{Al}-\mathrm{Mg}-\mathrm{Al}$ complex 42 with a Ti atom could also result in an $\mathrm{Al}-\mathrm{Ti}$ species.

Chapter 3 3.2.2. Mg/Ti Complex page 136

The following NMR-tube experiments were performed in $\mathrm{C}_{6} \mathrm{D}_{6}$ to find good reaction conditions. The starting material, either 41 or 42, was mixed with one, two or three equivalents of $\mathrm{TiCl}_{4}$ and the products were examined by ${ }^{1} \mathrm{H}$ NMR spectroscopy after being kept overnight. Scheme 3.21 summarizes the combinations of starting material, stoichiometry and the results from those reactions.

41

$46+$ others
(a)
(d)
(e)

Scheme 3.21. Formation of 46 from 41 and 42.

Both starting materials, 41 and 42, resulted in a product mixture containing common compound(s), labeled 46, in all runs, except for condition (c). These results suggest that starting with the $\mathrm{Al}-\mathrm{Mg}-\mathrm{Mg}$ complex 41 did not help to maintain Mg in the complex. Under condition (c), not only the Mg but also the Al was completely replaced by titanium to form the familiar geminal up/down Ti complex 30.

The X-ray diffractable crystals of the common product 46 were obtained from reaction using the condition (e) at larger scale. This reaction still did not produce a single

Chapter 3 3.2.3 Al/ti Complex page 137
compound: the 'H NMR spectrum of the crystals showed a mixture of two major products ( $1: 1$ ) and other minor species. One of the major products was 46 , and the other was labeled 46', which was not as dominant as 46 in the preliminary NMR-tube reactions.

The crystal structure shown in Figure $\mathbf{3 . 4 2}$ was obtained for these crystals by Xray crystallographic analysis from a weak data set (see Appendix A-16). However, it was not clear which of the two species, $\mathbf{4 6}$ or 46 ', gave the crystal structure. The two chlorides in the crystal structure are only tentatively assigned: one or both could be ethyl groups. Given the weak data, it was not possible to determine the identity of these groups based on the observed electron density.

Figure 3.42. X -ray crystallographic structure of $\mathbf{4 6}$ or $\mathbf{4 6}$ '. Cl 1 and Cl 2 may be either chlorides or ethyl groups.

Spectroscopically, both 46 and 46 ' seem like $\sigma$-symmetry species, based on the number of propyl $-\gamma-\mathrm{CH}_{3}$ groups and integration. The $\sigma$ symmetry of 46 ' is further assured by the aromatic signals; the aromatic signals of $\mathbf{4 6}$ remain ambiguous due to the severe overlapping. Both species seem to have one upfield ethyl group, which is considered to be equatorial at the terminal aluminum atom. From the features described above, both are reasonable candidates for the X -ray structure determination (Figure 3.46). From the similarities in spectroscopic features, the difference between 46 and $\mathbf{4 6}^{\prime}$ may only be in the two ambiguous axial groups, which can be either Cl or Et .

Although many ambiguities remain, 46 (or $46^{\prime}$ ) is the only crystallographically characterized $\mathrm{Al}-\mathrm{Ti}$ hetero-polymetallic complex obtained from ligand 7. Its crystal structure is quite similar to that of the $\mathbf{M g}-\mathrm{Ti}$ complex 45 discussed in the previous section. A Ti atom occupies the central position in both cases. Apparently, the central position, surrounded by all four oxygen donors, is a preferred place for the strongly oxophilic Ti(IV).

### 3.2.4. Other Attempts to Prepare Hetero-polymetallic Complexes

The addition of a range of aluminum reagents to a preformed titanium complex was investigated as an alternative route to $\mathrm{Al} / \mathrm{Ti}$ hetero-polymetallic systems. The reaction between the "vicinal up/down" di- $\mathrm{TiCl}_{2}$ (thf) complex 31 and two equivalents of $\mathrm{Me}_{3} \mathrm{Al}$ gave a fairly clean product that had $\sigma$ or $\boldsymbol{i}$ symmetry (i.e., two kinds of aryl rings were found). This reaction could not be reproduced, however, at least partly because the starting material may have converted to the "geminal up/down" di-TiCl ${ }_{2}$ (thf) complex 30a. Use of 33a, the bromo-analogue of 30a, did not give a clean product either; therefore, the symmetrical product observed from 31 was probably specific to the vicinal isomer. This approach was not further investigated due to the unavailability of the clean starting material (either 31 or 30a).

### 3.3. Conclusion

In this chapter, the capability of ligand 7 to form well-defined polymetallic complexes with $\mathrm{Mg}, \mathrm{Ti}$ and Al atoms, both homo- and hetero-metallic, has been demonstrated. Various bonding patterns were observed for different metal atoms and different combinations. The coordination variability arose from differences in metal's oxidation number and the number of available coordination sites.

Most of the Ti-only complexes formed two-up/two-down structures (30/30a, 33/33a, 34 and 35), with a "geminal up/down" dinuclear structure as the most favorable coordination pattern. The ligand was also capable of forming a "vicinal up/down" structure (31). The energy difference between "geminal up/down" and "vicinal up/down"
structures can be quite small when appropriate coordinating groups are attached, as seen in the equilibrium between $\mathbf{3 0} \mathbf{a}$ and 31.

The magnesium-only complexes ( 25 to 29) formed rigid trinuclear structures on an "all-up" oxo-surface-like ligand platform. The same structure was maintained in the mixed $\mathbf{M g}$-Al derivatives ( $\mathbf{4 1}$ to 44).

Some aluminum-only complexes showed a six-membered crown structure ( 37 and 38), but exposure of the aluminum complexes (37, $C$ and $F$ ) to excess THF resulted in a variety of different connectivities, a few of which were structurally confirmed. One of these structurally confirmed aluminum complexes (39) retained a dinuclear structure on an "all-up" ligand platform.

Dinuclear "all-up" structures were also found in Ti-containing hetero-bimetallic complexes (the Mg-Ti complex 45 and the AI-Ti complex 46/46'). In both cases, the titanium assumed the central position, surrounded by four oxygen donors, while the other metal atom took the terminal position.

In the construction of all hetero-polymetallic species, the balance in oxophilicity of the second-introduced metal and the nucleophilicity of the ArO[M] fragment from the first-introduced metal was important to avoid substituting all the first-contained metals with the incoming metals.

The basic knowledge of the reactivity and connectivity patterns imposed by these metals on ligand 7 provides a strong foundation for further exploration of coordination chemistry and catalysis using this newly developed ligand system.

### 3.4. Experimental

Instruments and Analysis: See the experimental Section of Chapter 1 (1.4).

General: All experiments were carried out in the drybox (see Chapter 1, Section 1.4). Most reactions were performed in 3-dram vials with plastic caps, stirred with a magnetic rod on a stirrer. "NMR-tube reaction" in this thesis means a reaction performed in an NMR tube in a deuterated solvent, mainly to monitor the reaction progress. Celite used for filtration was Celite 545 , dried in a vacuum oven $\left(50^{\circ} \mathrm{C}\right)$ at least three days. "Celitepacked pipette" was prepared by packing the dried Celite in a disposable pipette plugged with small piece of glass wool, and used for small-scale filtration. A glass-fritted funnel packed with the dried Celite was used for larger scale filtration. All glassware was dried at $120^{\circ} \mathrm{C}$ in an oven at least overnight right before bringing into the drybox.

Materials: Tetrakis(2-hydroxy-3-propylphenyl)ethene (7) was prepared as described in Chapter 1. THF, diethylether (ether), benzene, pentane and hexanes were purified by distillation from sodium benzophenone ketyl, degassed and stored in the drybox. Toluene was distilled over potassium, degassed and stored in the drybox. "Ethereal-solvent-free Toluene" was kept in a separate bottle, opened only when the drybox atmosphere was free of ethereal solvent vapor. All Grignard reagents, $\mathrm{TiCl}_{4}$ and alkylaluminum reagents $\left(\mathrm{Me}_{3} \mathrm{Al}, \mathrm{Et}_{3} \mathrm{Al}, \mathrm{Et}_{2} \mathrm{AlCl}\right.$ and $\left.\mathrm{EtAlCl}_{2}\right)$ were purchased from commercial vendors, stored in the drybox and used as is. The alkylaluminum reagents (kept in the original Aldrich Sure $/ \mathrm{Pac}^{\mathrm{TM}}$ metal cylinder) and $\mathrm{TiCl}_{4}$ were used under no-THF/ether atmosphere. $\mathrm{TiBr}_{4}$ was purified by triturating with hexanes to remove hydrate and other impurities, then recrystallizing from hexanes. NaH was freed from the oil in the drybox by washing with hexanes, dried under reduced pressure and kept in the drybox. $\mathrm{Bn}_{2} \mathrm{Mg}^{\circ} \mathrm{OEt}_{2},{ }^{13} \mathrm{CpTiCl}_{3},{ }^{14}$ and $\mathrm{TiBn}_{4}{ }^{15}$ were prepared by following published procedures.

Note: $" \mathrm{C}_{38} \mathrm{H}_{40} \mathrm{O}_{4}$ " represents the fully deprotonated ligand 7 i.e. $[7-4 H]$ (see the figure). The conformation is not restricted to the "all-up" form.

## 25: $\mathrm{C}_{38} \mathrm{H}_{4} \mathrm{O}_{4} \cdot \mathrm{Mg}_{3} \cdot \mathrm{Cl}_{2}{ }^{\circ}(\text { (thf })_{3}$

To a solution of tetrakis(2-hydroxy-3-propylphenyl)ethene (7) ( $1.8432 \mathrm{~g}, 3.2637 \mathrm{mmol}$ ) in 8 mL of THF was added a solution of $\mathrm{CH}_{3} \mathrm{MgCl} / \mathrm{THF}(3 \mathrm{M}, 4.4 \mathrm{~mL}, 13 \mathrm{mmol}$ ) dropwise at room temperature. A vigorous reaction with gas evolution, followed by the formation of white precipitate was observed. The color became yellow initially, but turned nearly colorless again upon completion of addition. After 10 more min. of stirring, the mixture was cooled to $-30^{\circ} \mathrm{C}$ overnight. The precipitated solid was collected and recrystallized to yield the desired product: Crop 1 ( $\mathrm{MW}=\mathbf{~ ' 9 2 0 . 4 , ' ~} 1.515 \mathrm{~g}, 38 \%$ ); Crop 2 (MW = '968.7,' $0.6895 \mathrm{~g}, 22 \%$ ); Crop 3 ( $\mathrm{MW}=$ ' 1036, ' $0.2016 \mathrm{~g}, 6 \%$ ). The mother liquor and the solution portion after the first cooling were combined, evaporated and triturated with toluene, filtered, concentrated and cooled to $-30^{\circ} \mathrm{C}$ to yield Crop 4 ( $0.2378 \mathrm{~g}, 7 \%$ ). Total yield was $73 \%$. The composition of each crop based on $\mathrm{C} / \mathrm{H}$ analysis ${ }^{16}$ is summarized in Table 3.11. The product from a separate small-scale reaction was crystallized from hot THF to give X-ray crystallographic quality crystals (Figure 3.3). Although the X-ray crystallography provided enough information of the connectivity of the atoms, the data was not worth further refinement because of the large residual factor ( $26 \%$ ). ' H NMR ( $360 \mathrm{MHz}, \mathrm{C}_{6} \mathrm{D}_{6}$ ): $\delta 7.01$ ( $4 \mathrm{H}, \mathrm{dd}, J=7.4,1.8 \mathrm{~Hz}$ ), 6.76 ( $4 \mathrm{H}, \mathrm{dd}, J=7.4$, $1.8 \mathrm{~Hz}), 6.60(4 \mathrm{H}, \mathrm{t}, J=7.4 \mathrm{~Hz}), 4.92\left(3.2 \mathrm{H}, \mathrm{m}\right.$, central THF- $\left.\alpha-\mathrm{CH}_{2}\right), 2.86(4+9.3 \mathrm{H}$, overlapping terminal THF- $\alpha-\mathrm{CH}_{2}$ and propyl $-\alpha-\mathrm{CH}_{2}$ ), $2.50\left(4 \mathrm{H}, \mathrm{m}\right.$, propyl $\left.-\alpha-\mathrm{CH}_{6}\right), 2.34$ ( $3.2 \mathrm{H}, \mathrm{m}$, central THF- $\beta-\mathrm{CH}_{2}$ ), $1.72\left(8 \mathrm{H}, \mathrm{m}\right.$, propyl $\left.-\beta-\mathrm{CH}_{2} \mathrm{H}_{\mathrm{b}}\right), 1.03(12 \mathrm{H}, \mathrm{t}, J=7.2 \mathrm{~Hz}$, propyl- $\beta-\mathrm{CH}_{2} \mathrm{H}_{\mathrm{b}}$ ), $0.76\left(9.3 \mathrm{H}, \mathrm{br}\right.$, terminal THF- $\boldsymbol{\beta}-\mathrm{CH}_{2}$ ). ${ }^{\mathbf{H}} \mathrm{H}$ NMR ( 360 MHz, THF- $\mathrm{d}_{8}$ ): $\boldsymbol{\delta}$ $6.91(4 \mathrm{H}, \mathrm{dd}, J=7.5,1.8 \mathrm{~Hz}), 6.69(4 \mathrm{H}, \mathrm{dd}, J=7.5,1.8 \mathrm{~Hz}), 6.40(4 \mathrm{H}, \mathrm{t}, J=7.5 \mathrm{~Hz})$, $3.62\left(-11 \mathrm{H}, \mathrm{m}\right.$, liberated THF), $2.71\left(4 \mathrm{H}, \mathrm{m}, \alpha-\mathrm{CH}_{3}\right), 2.27\left(4 \mathrm{H}, \mathrm{m}, \alpha-\mathrm{CH}_{\mathrm{b}}\right), 1.78(\sim 11 \mathrm{H}$, m , liberated THF), $1.58\left(4 \mathrm{H}, \mathrm{m}, \beta-\mathrm{CH}_{2}\right), 1.43\left(4 \mathrm{H}, \mathrm{m}, \beta-\mathrm{CH}_{6}\right), 0.85(12 \mathrm{H}, \mathrm{t}, J=7.2 \mathrm{~Hz}, \gamma-$ $\mathrm{CH}_{3}$ ). ${ }^{13} \mathrm{C}$ NMR ( $125 \mathrm{MHz}, \mathrm{APT}, \mathrm{C}_{6} \mathrm{D}_{6}$ ): $\delta 156.8\left(4^{\circ}\right)$, $148.4(\mathrm{C}=\mathrm{C}), 133.0\left(4^{\circ}\right), 131.8\left(4^{\circ}\right)$, 129.1, 127.1 ( $3^{\circ}$ ), 118.2 ( $3^{\circ}$ ), 71.6 (thf), 70.0 (thf), 33.6, 26.1 (thf), 24.7 (thf), 23.5, 14.3. 26

To a solution of tetrakis(2-hydroxy-3-propylphenyl)ethene (7) ( $0.3323 \mathrm{~g}, 0.5884 \mathrm{mmol}$ ) in $6 \sim 7 \mathrm{~mL}$ of THF was added a solution of $\mathrm{RMgCl} / \mathrm{Et}_{2} \mathrm{O}(\mathrm{R}=$ allyl, $1 \mathrm{M}, 3.08 \mathrm{~mL}, 3.1$ mmol ) dropwise at room temperature. A vigorous reaction with gas evolution was observed with color becoming yellow. The mixture became cloudy within 30 minutes. After 2 h , tiny crystals started to form. After cooling to $-30^{\circ} \mathrm{C}$ more crystals were formed. The isolated crystals were $\mathrm{MgBr}_{2}{ }^{\bullet}(\text { (thf })_{2}$, as determined by $\mathrm{C} / \mathrm{H}$ and Br elemental analysis. The volatiles were removed from the mother liquor, and the residue crystallized from toluene-hexane by slow diffusion and cooling to $-30^{\circ} \mathrm{C}$. The crystals obtained proved to be 26 (the yield was not recorded). More product was obtained from the mother liquors. The mother liquor after the crystallizations contained a byproduct $\mathbf{Z}$, that was most likely the alkylated complex ( Br replaced by allyl) due to the excess amount of the Grignard reagent used in the reaction. ${ }^{1} \mathrm{H}$ NMR ( $360 \mathrm{MHz}, \mathrm{C}_{6} \mathrm{D}_{6}$ ): $\delta \mathbf{6 . 9 9}$ ( $4 \mathrm{H}, \mathrm{dd}, J=7.5$, $1.8 \mathrm{~Hz}), 6.75(4 \mathrm{H}, \mathrm{dd}, J=7.5,1.8 \mathrm{~Hz}), 6.59(4 \mathrm{H}, \mathrm{t}, J=7.5 \mathrm{~Hz}), 4.93(4 \mathrm{H}, \mathrm{br}$, central THF- $\alpha-\mathrm{CH}_{2}$ ), $3.50\left(31 \mathrm{H}, \mathrm{br}\right.$, terminal THF- $\alpha-\mathrm{CH}_{2}$ plus free THF- $\alpha-\mathrm{CH}_{2}$ ), $2.88(4 \mathrm{H}, \mathrm{m}$, propyl $-\alpha-\mathrm{CH}_{\mathrm{a}}$ ), $2.50\left(4 \mathrm{H}, \mathrm{m}\right.$, propyl- $\alpha-\mathrm{CH}_{\mathrm{b}}$ ), 2.38 central THF- $\beta-\mathrm{CH}_{2}$ ), $1.72(8 \mathrm{H}, \mathrm{m}$,

propyl- $\left.\beta-\mathrm{CH}_{2} \mathrm{H}_{\mathrm{b}}\right), 1.20\left(31 \mathrm{H}, \mathrm{br}\right.$, terminal THF- $\beta-\mathrm{CH}_{2}$ plus free THF- $\beta-\mathrm{CH}_{2}$ ), $1.03(12 \mathrm{H}$, $t, J=7.5 \mathrm{~Hz}$ ). ${ }^{\text {h }} \mathrm{H}$ NMR ( 360 MHz, THF-d $\mathrm{d}_{8}$ ) $\delta 6.91(4 \mathrm{H}, \mathrm{dd}, J=7.5,1.8 \mathrm{~Hz}$ ), $6.70(4 \mathrm{H}$, dd, $J=7.5,1.8 \mathrm{~Hz}), 6.42(4 \mathrm{H}, \mathrm{t}, J=7.5 \mathrm{~Hz}), 3.62(\sim 16 \mathrm{H}, \mathrm{m}$, liberated THF), 2.74 (4H, $\left.\mathrm{m}, \alpha-\mathrm{CH}_{2}\right), 2.29\left(4 \mathrm{H}, \mathrm{m}, \alpha-\mathrm{CH}_{\mathrm{b}}\right), 1.78\left(\sim 16 \mathrm{H}, \mathrm{m}\right.$, liberated THF), $1.58\left(4 \mathrm{H}, \mathrm{m}, \beta-\mathrm{CH}_{2}\right)$, $1.45\left(4 \mathrm{H}, \mathrm{m}, \boldsymbol{\beta}-\mathrm{CH}_{\mathrm{b}}\right), 0.86\left(12 \mathrm{H}, \mathrm{t}, \mathrm{J}=7.2 \mathrm{~Hz}, \gamma-\mathrm{CH}_{3}\right) .{ }^{13} \mathrm{C}$ NMR ( $75 \mathrm{MHz}, \mathrm{APT}, \mathrm{C}_{6} \mathrm{D}_{6}$ ): $\delta$ 156.7 (4 ${ }^{\circ}$ ), $148.4\left(\mathrm{C}=\mathrm{C}\right.$ ), 133.1 ( $4^{\circ}$ ), 131.8 ( $4^{\circ}$ ), 129.1, 127.1, 118.3, 71.7 (thf), 70.4 (thf), 33.7, 26.1 (thf), 24.6 (thf), 23.6, 14.3. Anal. Calcd for $\mathrm{C}_{38} \mathrm{H}_{40} \mathrm{O}_{4} \cdot \mathrm{Mg}_{3} \bullet \mathrm{Br}_{2}{ }^{\bullet}(\text { thf })_{3}: \mathrm{C}, 59.47$; $\mathrm{H}, 6.39 ; \mathrm{Br}, 15.83$. Found: C, 56.5797 (av. of two runs, $\pm 0.0795$ ); $\mathrm{H}, 6.3284$ (av. of two runs, $\pm 0.0927$ ); $\mathrm{Br}, 19.75$ (av. of two runs, $\pm 0.995$ ). Composition obtained from the $\mathrm{C} / \mathrm{H}$ elemental analysis: ${ }^{16} \mathrm{C}_{38} \mathrm{H}_{40} \mathrm{O}_{4} \cdot \mathrm{Mg}_{3.42} \bullet \mathrm{Br}_{2.85} \bullet(\text { thf })_{3.99} ; ~ \mathrm{MW}=1145.4$. X -ray crystallography: see Appendix A-3.

27: $\mathrm{C}_{\mathbf{3 8}} \mathrm{H}_{\mathbf{4 0}} \mathrm{O}_{4} \cdot \mathbf{M g}_{\mathbf{3}} \cdot \mathrm{Cl}_{2} \cdot\left(\mathbf{E t}_{2} \mathbf{O}\right)_{\mathbf{3}}$

To a solution of tetrakis(2-hydroxy-3-propylphenyl)ethene (7) ( $0.2092 \mathrm{~g}, 0.3704 \mathrm{mmol}$ ) in 2 mL of $\mathrm{Et}_{2} \mathrm{O}$ was added a solution of $\mathrm{BnMgCl} / \mathrm{Et}_{2} \mathrm{O}(1.0 \mathrm{M}, 1.48 \mathrm{~mL}, 1.48 \mathrm{mmol})$ dropwise at room temperature. A vigorous reaction with gas evolution, a color change to yellow, and subsequent precipitate formation were observed. After stirring the mixture overnight, the solids redissolved and the solution became less colored (pale yellow). The solution was passed through Celite and evaporated. The residue did not dissolve in $\mathrm{Et}_{2} \mathrm{O}$ completely, thus it was triturated with $\mathrm{Et}_{2} \mathrm{O}$. After filtration and concentration, the mixture was heated slightly then cooled to r.t.; and then $-30^{\circ} \mathrm{C}$. The partly powdery crystals were collected and dried under reduced pressure ( $0.0363 \mathrm{~g}, 11 \%$ ). The mother liquor still contained considerable amount of the product but no further crystallization was performed. The ${ }^{1} H$ NMR spectrum of the compound in THF- $\mathrm{d}_{8}$ showed peaks of the ligand framework identical to those of $\mathrm{C}_{38} \mathrm{H}_{40} \mathrm{O}_{4} \cdot \mathrm{Mg}_{3}{ }^{\bullet} \mathrm{Cl}_{2} \bullet(\mathrm{thf})_{3}(25)$ with approximately three equivalents of liberated $\mathrm{Et}_{2} \mathrm{O}$; which means that these two compounds were identical except for the coordinating solvent, which was liberated and replaced
completely by THF- $\mathrm{d}_{\mathrm{g}}$ in both cases to show the identical spectrum. Anal. Calcd for $\mathrm{C}_{38} \mathrm{H}_{40} \mathrm{O}_{4} \cdot \mathrm{Mg}_{3}{ }^{\bullet} \mathrm{Cl}_{2}{ }^{\bullet}\left(\mathrm{OEt}_{2}\right)_{3}$ : C, 64.79; $\mathrm{H}, 7.61 ; \mathrm{Cl}, 7.65$. Found: $\mathrm{C}, 65.04 ; \mathrm{H}, 7.69 ; \mathrm{Cl}, 7.58$.

## 28: $\mathrm{C}_{\mathbf{3}} \mathrm{H}_{\mathbf{4 0}} \mathbf{O}_{4} \mathbf{A M g}_{\mathbf{3}}{ }^{\mathbf{0}}\left(\mathrm{CH}_{\mathbf{3}}\right)_{\mathbf{2}} \mathbf{\bullet}(\mathrm{thf})_{\mathbf{n}}$

Method A. To a solution of $25(0.0604 \mathrm{~g}, 0.0626 \mathrm{mmol})$ in $2 \sim 3 \mathrm{~mL}$ of THF was added the $\mathrm{CH}_{3} \mathrm{MgCl} / \mathrm{THF}(3 \mathrm{M}, 0.05 \mathrm{~mL}, 0.15 \mathrm{mmol}$ ) and stirred for overnight. No visible change was observed. The volatiles were removed in vacuo. The solution of the residue in THF- $\mathrm{d}_{8}$ showed a clean single product in the ${ }^{1} \mathrm{H}-\mathrm{NMR}$ spectrum, together with a peak from some Grignard reagent(s). The residue was recrystallized together with the Method $B$ product.
Method B. To a solution of tetrakis(2-hydroxy-3-propylphenyl)ethene (7) ( 0.0484 g , 0.0857 mmol ) in 0.5 mL of THF was added $\mathrm{CH}_{3} \mathrm{MgCl} / \mathrm{THF}(3 \mathrm{M}, 0.17 \mathrm{~mL}, 0.51 \mathrm{mmol}$ ) dropwise at room temperature. A vigorous reaction with gas evolution was observed. The color became slightly yellow initially, but turned nearly colorless again upon completion of the addition. After stirring overnight, the volatiles were removed from the solution in vacuo. The residue showed the same signals as the Method A product in the ${ }^{1} \mathrm{H}-\mathrm{NMR}$ spectrum, except that there was little Grignard reagent signal left. The residue was triturated with toluene, filtered through Celite-packed pipette, and the volatiles were removed. The residue was combined with the product of the Method $\boldsymbol{A}$ and crystallized from toluene (r.t. $\rightarrow-30^{\circ} \mathrm{C}$ ). Shiny block crystals among tiny particles were grown. Xray crystallography confirmed the structure. The solid was removed from the mother liquor, washed with cold toluene and dried under reduced pressure. The product yield was 0.0657 g ( $50 \%$ ) although the elemental analysis for $\mathrm{C} / \mathrm{H}$ did not give a good match with the calculated values, probably due to contamination by the residual Grignard reagents and/or $\mathrm{MgCl}_{2}{ }^{\circ}(\text { (thf })_{x}$.
${ }^{1} \mathrm{H}$ NMR ( $360 \mathrm{MHz}, \mathrm{THF}-\mathrm{d}_{8}$ ): $\delta 6.90(4 \mathrm{H}, \mathrm{dd}, J=7.5,1 \mathrm{~Hz}), 6.66(4 \mathrm{H}, \mathrm{dd}, J=7.5,1 \mathrm{~Hz})$, $6.36(4 \mathrm{H}, \mathrm{t}, J=7.5 \mathrm{~Hz}), 3.62(\sim 29 \mathrm{H}, \mathrm{m}$, THF liberated from the complex combined with excess free THF), $2.60\left(4 \mathrm{H}, \mathrm{m}, \alpha-\mathrm{CH}_{\mathrm{a}}\right), 2.29\left(4 \mathrm{H}, \mathrm{m}, \alpha-\mathrm{CH}_{\mathrm{b}}\right), 1.78(\sim 29 \mathrm{H}, \mathrm{m}, \mathrm{THF}$

Chapter 3 3.4. Experimental page 145
liberated from the complex combined with excess free THF), $1.57\left(4 \mathrm{H}, \mathrm{m}, \beta-\mathrm{CH}_{2}\right), 1.47$ $\left(4 \mathrm{H}, \mathrm{m}, \beta-\mathrm{CH}_{\mathrm{b}}\right), 0.83\left(12 \mathrm{H}, \mathrm{t}, \mathrm{J}=7.2 \mathrm{~Hz}, \gamma-\mathrm{CH}_{3}\right),-1.53\left(6 \mathrm{H}, \mathrm{br} \mathrm{s}, \mathrm{CH}_{3}\right) .{ }^{13} \mathrm{C}$ NMR ( 100 $\mathrm{MHz}, \mathrm{BB}, \mathrm{THF}-\mathrm{d}_{8}$ ): $\delta 158.3\left(4^{\circ}\right), 148.9\left(4^{\circ}\right), 132.9\left(4^{\circ}\right), 132.6$ ( $4^{\circ}$ ), 128.9 ( $3^{\circ}$ ), 127.6 $\left(3^{\circ}\right), 117.5\left(3^{\circ}\right), 68.2$ (liberated THF), 34.3, 26.4 (liberated THF), 23.9, 14.5, -17.3 $\left(\mathrm{MgCH}_{3}\right)$. Anal. Calcd for $\mathrm{C}_{38} \mathrm{H}_{40} \mathrm{O}_{4} \bullet \mathrm{Mg}_{3}{ }^{\circ}\left(\mathrm{CH}_{3}\right)_{2}{ }^{\circ}(\mathrm{thf})_{3}: \mathrm{C}, 70.97 ; \mathrm{H}, 8.02$. Found: C, 66.61; H, 7.57. X-ray crystallography: see Appendix A-4.

## 29: $\mathrm{C}_{38} \mathrm{H}_{40} \mathrm{O}_{4} \cdot \mathrm{Mg}_{3} \bullet \mathrm{Bn}_{2} \bullet\left(\mathrm{OEt}_{2}\right)$

Method A. The reaction mixture and the products were kept from any contact with THF throughout the procedure. To a solution of tetrakis(2-hydroxy-3-propylphenyl)ethylene (7) $(0.1105 \mathrm{~g}, 0.1957 \mathrm{mmol})$ in 1 mL of $\mathrm{Et}_{2} \mathrm{O}$ was added the solution of $\mathrm{Bn}_{2} \mathrm{Mg}^{\circ} \mathrm{OEt}_{2}$ ( $0.2775 \mathrm{~g}, 0.7821 \mathrm{mmol}$ ) in 3 mL of $\mathrm{Et}_{2} \mathrm{O}$ dropwise. A vigorous reaction with gas evolution and immediate precipitation were observed. The color became slightly yellow initially, but turned nearly colorless again upon completion of the addition. After stirring for 3 h , the cloudy mixture was cooled to $-30^{\circ} \mathrm{C}$. The big crystals among a white powder were $\mathrm{Bn}_{2} \mathrm{Mg}^{\circ} \mathrm{OEt}_{2}$, and the powder was identified as the product based on ${ }^{\prime} \mathrm{H}-\mathrm{NMR}$ spectroscopy in THF-d. The powder was collected and washed twice with a small amount of $\mathrm{Et}_{2} \mathrm{O}$ using the centrifuge, then dried under reduced pressure. The washings contained only $\mathrm{Bn}_{2} \mathrm{Mg}^{\circ} \mathrm{OEt}_{2}$. The washed and dried powder $(0.1040 \mathrm{~g}, 85 \%$ if the formula is as expected) showed a fairly clean product with only 1 equiv. of liberated $\mathrm{Et}_{2} \mathrm{O}$ per ligand in the 'H-NMR spectrum in THF- $\mathrm{d}_{8}$. Elemental analysis for this compound is ambiguous, because the weight of the sample was changing while weighing the sample.
Method B. To a solution of tetrakis(2-hydroxy-3-propylphenyl)ethylene (7) (0.1810 g, 0.3205 mmol ) in diethyl ether ( 1.5 mL ) was added BnMgCl ( $1.0 \mathrm{M} /$ ether, $2.2 \mathrm{~mL}, 2.2$ mmol). Gas evolution was noted, with color turning more yellow and precipitate formation. After stirring the mixture for 4 h , all the precipitate was found to have dissolved. After a total of 18 h , the volatiles were removed from the reaction mixture to give a foamy, sticky residue. The 'H NMR spectrum in THF-d $\mathrm{d}_{8}$ showed the same product
as the result from Method A. Crystallization from different combinations of ether, toluene and hexanes has not been successful.
${ }^{1} \mathrm{H}$ NMR ( $360 \mathrm{MHz}, \mathrm{THF}-\mathrm{d}_{8}$ ): $\boldsymbol{\delta} \mathbf{6 . 8 6}(\mathbf{4 H}, \mathrm{dd}, J=7.5,1.8 \mathrm{~Hz}), 6.79(8 \mathrm{H}, \mathrm{m}, \mathrm{Bn}), 6.65$ ( $4 \mathrm{H}, \mathrm{dd}, J=7.5,1 \mathrm{~Hz}$ ), $6.39(2 \mathrm{H}$, overlapping, Bn), $6.36(4 \mathrm{H}, \mathrm{t}, J=7.5 \mathrm{~Hz}), 3.38(4 \mathrm{H}, \mathrm{q}$, $J=7 \mathrm{~Hz}$, liberated $\left.\mathrm{Et}_{2} \mathrm{O}\right), 2.67\left(4 \mathrm{H}, \mathrm{m}, \alpha-\mathrm{CH}_{2}\right), 2.30\left(4 \mathrm{H}, \mathrm{m}, \alpha-\mathrm{CH}_{\mathrm{b}}\right), 1.64(4 \mathrm{H}, \mathrm{m}, \beta$ $\left.\mathrm{CH}_{2}\right), 1.54\left(4 \mathrm{H}, \mathrm{m}, \beta-\mathrm{CH}_{6}\right), 1.46\left(4 \mathrm{H}, \mathrm{s}\right.$, benzyl- $\left.\mathrm{CH}_{2}\right), 1.12(6 \mathrm{H}, \mathrm{t}, J=7 \mathrm{~Hz}$, liberated $\left.\mathrm{Et}_{2} \mathrm{O}\right), 0.93\left(12 \mathrm{H}, \mathrm{t}, J=7.5 \mathrm{~Hz}, \gamma-\mathrm{CH}_{3}\right) .{ }^{13} \mathrm{C}$ NMR ( 125 MHz, THF- $\mathrm{d}_{8}$ ): $\delta 157.8$ (4 ${ }^{\circ}$ ), $156.2\left(4^{\circ}\right), 149.1\left(4^{\circ}\right), 132.8\left(4^{\circ}\right), 132.7\left(4^{\circ}\right), 128.8\left(3^{\circ}\right), 128.5\left(3^{\circ}\right), 127.6\left(3^{\circ}\right), 124.7\left(3^{\circ}\right)$, $117.9\left(3^{\circ}\right), 117.5\left(3^{\circ}\right), 66.3$ (liberated $\left.\mathrm{Et}_{2} \mathrm{O}\right), 34.2,23.7,21.6\left(\mathrm{PhCH}_{2}\right), 15.7$ (liberated $\left.\mathrm{Et}_{2} \mathrm{O}\right)$, 14.6. Anal. Calcd for $\mathrm{C}_{38} \mathrm{H}_{40} \mathrm{O}_{4} \bullet \mathrm{Mg}_{3}{ }^{\bullet}\left(\mathrm{C}_{7} \mathrm{H}_{7}\right)_{2}{ }^{\bullet} \mathrm{O}\left(\mathrm{C}_{2} \mathrm{H}_{5}\right)_{2}: \mathrm{C}, 75.57 ; \mathrm{H}, 7.25$. Found: ${ }^{\mathrm{r}}$ (1) C, 69.79; H, 7.07. (2) C, 73.16; H, 7.52.

30: $\mathrm{C}_{\mathbf{3 0}} \mathrm{H}_{40} \mathrm{O}_{4}$ •(gem-TiCl $)_{2}$ (geminal up/down)

7

30
(A) Without pre-deprotonation. The reaction mixture and the products were kept from any contact with THF or $\mathrm{Et}_{2} \mathrm{O}$ throughout the procedure. To a solution of tetrakis(2-hydroxy-3-propylphenyl)ethylene (7) ( $0.0546 \mathrm{~g}, 0.0967 \mathrm{mmol}$ ) in 1 mL of toluene was added $\mathrm{TiCl}_{4}(0.0373 \mathrm{~g}, 0.197 \mathrm{mmol})$ dissolved in 2 mL of toluene. The color turned rubyred immediately. After stirring the mixture for 30 minutes, the volatiles were removed in vacuo. The red residue was washed with pentane, triturated with toluene and filtered through Celite-packed pipette. The triturate was evaporated to give dark red powder. The ${ }^{1}$ H NMR spectroscopy of this crude product showed fairly clean desired complex 30. The

[^9]yield was not recorded. The structure was determined by analogy to the THFcoordinated version, 30a (next section), based on the similarity of the 'H NMR spectroscopy.
(B) With pre-deprotonation (NMR-tube reaction only). Tetrakis(2-hydroxy-3propylphenyl)ethylene ( 7 ) ( $0.0457 \mathrm{~g}, 0.0809 \mathrm{mmol}$ ) and $\mathrm{NaH}(0.0078 \mathrm{~g}, 0.32 \mathrm{mmol})$ were mixed in ca. $0.5 \mathrm{~mL} \mathrm{C}_{6} \mathrm{D}_{6}$ in an NMR tube for 6 h , then $\mathrm{TiCl}_{4}(0.0312 \mathrm{~g}, 0.164 \mathrm{mmol})$ was added with small amount of additional $\mathrm{C}_{6} \mathrm{D}_{6}$. The color turned ruby-red immediately. Due to the cloudiness of the sample, the mixture was filtered through Celite-packed pipette, and the solution part was checked by ' H NMR spectroscopy at 20 minutes after the addition of $\mathrm{TiCl}_{4}$. The spectrum showed the product 30 as a major product, accompanied by other unidentified species. After one day, the same solution showed a cleaner spectrum of 30.
${ }^{1} \mathrm{H}$ NMR ( $360 \mathrm{MHz}, \mathrm{C}_{6} \mathrm{D}_{6}$ ): $\delta 7.88(4 \mathrm{H}, \mathrm{dd}, J=7.5, \sim 1 \mathrm{~Hz}), 6.74(4 \mathrm{H}, \mathrm{t}, J=7.5 \mathrm{~Hz}), 6.49$ ( $4 \mathrm{H}, \mathrm{dd}, J=7.5, \sim 1 \mathrm{~Hz}$ ), $2.60\left(4 \mathrm{H}, \mathrm{m}, \alpha-\mathrm{CH}_{2}\right), 2.31\left(4 \mathrm{H}, \mathrm{m}, \alpha-\mathrm{CH}_{6}\right), 1.40-1.38(8 \mathrm{H}, \mathrm{m}, \beta-$ $\left.\mathrm{CH}_{2} \mathrm{H}_{\mathrm{b}}\right), 0.73\left(12 \mathrm{H}, \mathrm{t}, \mathrm{J}=7.5 \mathrm{~Hz}, \gamma-\mathrm{CH}_{3}\right)$.

30a and 30b/31: geminal and vicinal up/down $\mathrm{C}_{38} \mathrm{H}_{40} \mathrm{O}_{4} \cdot\left\{\mathrm{TiBr}_{2}(\mathrm{th})\right\}_{2}$

Three slightly different conditions are presented as follows: (1) the conditions under which "30a" was isolated, (2) the conditions under which "30b" was isolated, and (3) the conditions under which the crystals of " 31 " were obtained. These conditions are not optimized.
(1) Conditions under which "30a" was isolated. To a solution of 25 (FW = 965 based on the elemental analysis; $0.0848 \mathrm{~g}, 0.879 \mathrm{mmol}$ ) in 3 mL of toluene was added $\mathrm{TiCl}_{4}$ ( $0.0345 \mathrm{~g}, 0.182 \mathrm{mmol}$ ) dissolved in 1 mL of toluene. The color turned ruby-red immediately. After overnight, the volatiles were removed in vacuo. The residue was triturated with toluene and filtered through a Celite-packed pipette. The residue after

Chapter 3 3.4. Experimental page 148
removal of the volatiles in vacuo was fairly pure product $30 \mathrm{a}(0.080 \mathrm{~g}, 96 \%$ ). Analytically pure product as a bulk could not be obtained due to the isomerization of $\mathbf{3 0 a}$ to 30b/31, as well as the gradual formation of 32. Co-crystals of 30a and 32 (2:1 ratio) were obtained from one of many crystallization attempts, mainly from toluene-pentane or toluene-hexane by slow diffusion or slow-evaporation. The crystallization batch that produced the light-red co-crystals of 30 a and 32 also produced dark-red crystals, which were single crystals of $\mathbf{3 0 a}$, according to the ${ }^{1} \mathrm{H}$ NMR spectrum. ${ }^{1} \mathrm{H}$ NMR $(360 \mathrm{MHz}$, $\left.\mathrm{C}_{6} \mathrm{D}_{6}\right): \delta 7.88(4 \mathrm{H}, \mathrm{dd}, J=7.5,1.8 \mathrm{~Hz}), 6.69(4 \mathrm{H}, \mathrm{t}, J=7.5 \mathrm{~Hz}), 6.70(4 \mathrm{H}, \mathrm{dd}, J=7.5,1.8$ $\mathrm{Hz}), 4.35\left(4 \mathrm{H}, \mathrm{m}, \mathrm{THF}-\alpha-\mathrm{CH}_{2}\right), 2.73\left(4 \mathrm{H}, \mathrm{m}, \alpha-\mathrm{CH}_{2}\right), 2.47\left(4 \mathrm{H}, \mathrm{m}, \alpha-\mathrm{CH}_{\mathrm{b}}\right), 1.50(8 \mathrm{H}, \mathrm{m}$, $\left.\beta-\mathrm{CH}_{2} \mathrm{H}_{\mathrm{b}}\right), 1.46\left(4 \mathrm{H}, \mathrm{m}\right.$, THF- $\left.\beta-\mathrm{CH}_{2}\right), 0.83\left(12 \mathrm{H}, \mathrm{t}, \mathrm{J}=7.3 \mathrm{~Hz}, \gamma-\mathrm{CH}_{3}\right) .{ }^{13} \mathrm{C}$ NMR: A clean spectrum could not be obtained due to the tendency to isomerize to $\mathbf{3 0 b} / 31$. X-ray crystallography: see Appendix A-5 (co-crystal of 30a and 32).
(2) Conditions under which "30b" was isolated. To a solution of 25 ( $\mathrm{FW}=965$ based on the elemental analysis; $0.2196 \mathrm{~g}, 0.227 \mathrm{mmol}$ ) in 4 mL of toluene was added $\mathrm{TiCl}_{4}$ ( $0.0959 \mathrm{~g}, 0.506 \mathrm{mmol}$ ) dissolved in 1 mL of toluene. The color turned ruby-red immediately. After overnight, the volatiles were removed in vacuo. The residue was triturated with toluene and filtered through a Celite-packed pipette. After removal of the volatiles in vacuo from the triturate, the residue was crystallized from toluene (hot to r.t.) followed by slow diffusion of hexanes layered on top of the toluene solution. A total of $0.0477 \mathrm{~g}(23 \%)$ of analytically pure vicinal up/down isomer 30b was obtained as the first and the second crops of the slow-process crystallization. The isomer 30b was identified as "31" as discussed in Section 3.1.2.E. ${ }^{1} \mathrm{H}$ NMR ( $360 \mathrm{MHz}, \mathrm{C}_{6} \mathrm{D}_{6}$ ): $\delta 7.875(4 \mathrm{H}$, dd, $J=$ $7.5,1.8 \mathrm{~Hz}), 6.75(4 \mathrm{H}, \mathrm{dd}, J=7.5,1.8 \mathrm{~Hz}), 6.70(4 \mathrm{H}, \mathrm{t}, J=7.5 \mathrm{~Hz}), 4.38(4 \mathrm{H}, \mathrm{m}, \mathrm{THF}-\alpha-$ $\mathrm{CH}_{2}$ ), $2.81\left(4 \mathrm{H}, \mathrm{br}, \alpha-\mathrm{CH}_{2}\right), 2.68\left(4 \mathrm{H}, \mathrm{m}, \alpha-\mathrm{CH}_{\mathrm{b}}\right), 1,49\left(8 \mathrm{H}, \mathrm{m}, \beta-\mathrm{CH}_{2} \mathrm{H}_{\mathrm{b}}\right), 1.40(4 \mathrm{H}, \mathrm{m}$, THF- $\beta-\mathrm{CH}_{2}$ ), $0.88\left(12 \mathrm{H}, \mathrm{t}, J=7.3 \mathrm{~Hz}, \gamma-\mathrm{CH}_{3}\right) .{ }^{13} \mathrm{C}$ NMR: A clean spectrum was not obtained due to partial isomerization to 30a. Anal. Calcd for $\mathrm{C}_{38} \mathrm{H}_{40} \mathrm{O}_{4} \cdot \mathrm{Ti}_{2} \cdot \mathrm{Cl}_{4} \bullet\left(\mathrm{C}_{4} \mathrm{H}_{8} \mathrm{O}\right)_{2}$ : C, 58.62; H, 5.99; Cl, 15.05. Found: C, 58.44; H,5.81; Cl, 14.98 .
(3) Conditions that gave the X-ray quality crystals of "31." To a solution of 25 (FW = 1235 based on the elemental analysis; $0.162 \mathrm{~g}, 0.0178 \mathrm{mmol}$ ) in 1 mL of toluene was added $\mathrm{TiCl}_{4}(0.0071 \mathrm{~g}, 0.037 \mathrm{mmol})$ dissolved in 0.5 mL of toluene. The color turned ruby-red immediately. After overnight, another portion of $\mathrm{TiCl}_{4}(0.0069 \mathrm{~g}, 0.036 \mathrm{mmol})$ was added with 0.5 mL of toluene. After 15 minutes, the volatiles were removed in vacuo. The residue was triturated with toluene, filtered through a Celite-packed pipette, concentrated in vacuo and cooled to $-30^{\circ} \mathrm{C}$. Light orange crystals were formed, which turned out to be $\left[\mathrm{Cl}_{3}(\mathrm{thf}) \mathrm{Ti}-\mu-\mathrm{Cl}_{2}\right.$, as confirmed by preliminary X -ray analysis. The mother liquor was then removed from the crystals, evaporated, and the residue was
washed with pentane. The residue was then redissolved in toluene, small amount of pentane was layered on, and set aside for slow diffusion/slow evaporation. This batch, however, did not give good quality crystals. The pentane washings, after concentrating slightly and allowing slow evaporation, produced red-orange crystals that were analyzed by X-ray crystallography as the vicinal up/down complex 31. The 'H NMR spectroscopy of the evaporated mother liquor, after removing the crystals for X-ray analysis, was of questionable identity (Section 3.1.2.E). X-ray crystallography: see Appendix A-7 (31).

32: $\left(\mathrm{C}_{38} \mathrm{H}_{40} \mathrm{O}_{4}\right)_{2} \cdot \mathrm{Ti}_{2}$

32

To a solution of tetrakis(2-hydroxy-3-propylphenyl)ethylene (7) ( $0.0163 \mathrm{~g}, 0.0289 \mathrm{mmol}$ ) in 1 mL of toluene was added $\mathrm{NaH}(0.0030 \mathrm{~g}, 0.125 \mathrm{mmol})$ dissolved in 1 mL of toluene. The color turned slightly yellow. After stirring the mixture for 5 minutes, $\mathrm{TiCl}_{4}(0.0056$ $\mathrm{g}, 0.030 \mathrm{mmol}$ ) was added with 2 mL of toluene. After overnight, the red mixture was almost clear, with some fuzzy stuff at the bottom. After removal of the volatiles, the residue was triturated with toluene, filtered through Celite-packed pipette, and the volatiles were removed to give quite clean product as confirmed by ${ }^{1} H$ NMR spectroscopy. The yield was 0.0173 g (99\%). The structure was identified by X-ray crystallography of the co-crystal of $\mathbf{3 0 a}$ and 32 (see previous section). ${ }^{1} \mathrm{H}$ NMR ( 360 $\left.\mathrm{MHz}, \mathrm{C}_{6} \mathrm{D}_{6}\right): \delta 8.01(1 \mathrm{H}, \mathrm{dd}, J=7.8,1.8 \mathrm{~Hz}), 7.45(1 \mathrm{H}, \mathrm{dd}, J=7.5,1.8 \mathrm{~Hz}), 6.88(4 \mathrm{H}, \mathrm{t}$, $J=7.5 \mathrm{~Hz}), 6.85 \sim 6.79(5 \mathrm{H}$, overlapping $), 6.72(1 \mathrm{H}, \mathrm{dd}, J=7.5,1.5 \mathrm{~Hz}), 6.58 \sim 6.55(3 \mathrm{H}$, overlapping), 3.57 ( $1 \mathrm{H}, \mathrm{m}, \alpha-\mathrm{CH}$ ), $2.57 \sim 2.44$ ( $3 \mathrm{H}, \mathrm{m}$, overlapping, $\alpha-\mathrm{CH}$ ), $2.42(2 \mathrm{H}, \mathrm{t}, \mathrm{J}$ $\left.=8 \mathrm{~Hz}, \alpha-\mathrm{CH}_{2}\right), 2.17 \sim 2.13(2 \mathrm{H}, \mathrm{m}$, overlapping, $\alpha-\mathrm{CH}), 1.53 \sim 1.29(8 \mathrm{H}, \mathrm{m}$, overlapping, $\beta-\mathrm{CH}), 0.87\left(3 \mathrm{H}, \mathrm{t}, J=7.5 \mathrm{~Hz}, \gamma-\mathrm{CH}_{3}\right), 0.84\left(3 \mathrm{H}, \mathrm{t}, J=7.5 \mathrm{~Hz}, \gamma-\mathrm{CH}_{3}\right), 0.77(3 \mathrm{H}, \mathrm{t}, J=$ $\left.7.5 \mathrm{~Hz}, \gamma-\mathrm{CH}_{3}\right), 0.37\left(3 \mathrm{H}, \mathrm{t}, J=7.5 \mathrm{~Hz}, \gamma-\mathrm{CH}_{3}\right) . \mathrm{MS}(\mathrm{ES}) \mathrm{m} / \mathrm{z}$ : Calcd for $\mathrm{C}_{76} \mathrm{H}_{80} \mathrm{O}_{8} \mathrm{Ti}_{2}$ : 1216.48. Found: 1239 (55\%) [ $\mathrm{M}+\mathrm{Na}]^{+}$.

X-ray crystallography: see Appendix A-5 (co-crystal of 30a and 32) and A-6 (obtained from one of the failed attempts to produce 45).

## 33: $\mathrm{C}_{\mathbf{3 8}} \mathrm{H}_{40} \mathrm{O}_{4} \bullet\left(\mathrm{gem}-\mathrm{TiBr}_{\mathbf{2}}\right)_{\mathbf{2}}{ }^{\bullet}(\text { (thf) })_{\mathbf{2}}$ (geminal up/down)

The reaction mixture and the product were kept from any contact with THF or $\mathrm{Et}_{2} \mathrm{O}$ throughout the procedure. Tetrakis(2-hydroxy-3-propylphenyl)ethylene (7) ( 0.0409 g , $0.0724 \mathrm{mmol})$ and $\mathrm{NaH}(0.0070 \mathrm{~g}, 0.29 \mathrm{mmol})$ were mixed in ca. 0.5 mL of $\mathrm{C}_{6} \mathrm{D}_{6}$ in an NMR tube. After $4 \mathrm{~h}, \mathrm{TiBr}_{4}(0.0537 \mathrm{~g}, 0.146 \mathrm{mmol})$ was added, dissolved in a small amount of additional $\mathrm{C}_{6} \mathrm{D}_{6}$. The ${ }^{1} \mathrm{H}$ NMR spectrum observed 5 minutes after the $\mathrm{TiBr}_{4}$ addition showed clean 33 (the inorganic byproduct, NaBr , precipitated to the bottom of the solution so NMR spectroscopy was possible). The same solution showed an increase in minor unidentified byproducts over time. The structure was determined by analogy to the THF- coordinated version, 33a (next section), based on the similarity of ${ }^{1} \mathrm{H}$ NMR spectra. 'H NMR ( $360 \mathrm{MHz}, \mathrm{C}_{6} \mathrm{D}_{6}$ ): $\delta 7.86(4 \mathrm{H}, \mathrm{dd}, J=7.5,1.3 \mathrm{~Hz}), 6.765(4 \mathrm{H}, \mathrm{t}, J=7.5$ $\mathrm{Hz}), 6.51(4 \mathrm{H}, \mathrm{dd}, J=7.5,1.3 \mathrm{~Hz}), 2.705\left(4 \mathrm{H}, \mathrm{m}, \alpha-\mathrm{CH}_{2}\right), 2.36\left(4 \mathrm{H}, \mathrm{m}, \alpha-\mathrm{CH}_{\mathrm{b}}\right), 1.45$ $\left(8 \mathrm{H}, \mathrm{m}, \beta-\mathrm{CH}_{\mathrm{a}} \mathrm{H}_{\mathrm{b}}\right), 0.765\left(12 \mathrm{H}, \mathrm{t}, \mathrm{J}=7.2 \mathrm{~Hz}, \gamma-\mathrm{CH}_{3}\right)$.

## 33a: $\mathrm{C}_{\mathbf{3 8}} \mathrm{H}_{40} \mathrm{O}_{4} \bullet\left(\mathrm{gem}-\mathrm{TiBr}_{2}\right)_{\mathbf{2}} \bullet(\text { thf })_{\mathbf{2}}$ (geminal up/down)

Chapter 3 3.4. Experimental page 151

To a solution of 25 ( $\mathrm{FW}=965$ based on the elemental analysis; $0.0358 \mathrm{~g}, 0.0371 \mathrm{mmol}$ ) in 2 mL of toluene was added $\mathrm{TiBr}_{4}(0.0295 \mathrm{~g}, 0.0803 \mathrm{mmol})$ dissolved in 1 mL of toluene. The color turned dark-red immediately. After overnight, the volatiles were removed in vacuo. The residue was triturated with toluene, filtered through a Celitepacked pipette, and concentrated. Cooling the concentrated solution to $-30^{\circ} \mathrm{C}$ produced ruby-red prism crystals of 33a. The yield was not recorded, but the NMR-tube reaction of the same reaction in $\mathrm{C}_{6} \mathrm{D}_{6}$ medium showed that the reaction is clean and quantitative. ${ }^{1} \mathrm{H}$ NMR ( $360 \mathrm{MHz}, \mathrm{C}_{6} \mathrm{D}_{6}$ ): $\delta 7.87(4 \mathrm{H}, \mathrm{dd}, J=7.2,2 \mathrm{~Hz}), 6.69(4 \mathrm{H}, \mathrm{t}, J=7.2 \mathrm{~Hz}), 6.70(4 \mathrm{H}$, dd, $J=7.2,2 \mathrm{~Hz}), 4.46\left(4 \mathrm{H}, \mathrm{m}, \mathrm{THF}-\alpha-\mathrm{CH}_{2}\right), 2.88\left(4 \mathrm{H}, \mathrm{m}, \alpha-\mathrm{CH}_{2}\right), 2.55\left(4 \mathrm{H}, \mathrm{m}, \alpha-\mathrm{CH}_{\mathrm{t}}\right)$, $1.58\left(8 \mathrm{H}, \mathrm{m}, \beta-\mathrm{CH}_{2} \mathrm{H}_{\mathrm{b}}\right), 1.57\left(4 \mathrm{H}, \mathrm{m}, \mathrm{THF}-\beta-\mathrm{CH}_{2}\right), 0.88\left(12 \mathrm{H}, \mathrm{t}, J=7.3 \mathrm{~Hz}, \gamma-\mathrm{CH}_{3}\right) .{ }^{13} \mathrm{C}$ NMR ( $75 \mathrm{MHz}, \mathrm{APT}, \mathrm{C}_{6} \mathrm{D}_{6}$ ): $\delta 166.4$ ( $4^{\circ}, \mathrm{C}-\mathrm{O}$ ), 138.6 ( $4^{\circ}, \mathrm{C}=\mathrm{C}$ ), 134.9 ( $4^{\circ}$ ), 130.3 ( $4^{\circ}$ ), $129.0\left(3^{\circ}\right), 128.8\left(3^{\circ}\right), 124.0\left(3^{\circ}\right), 74.2$ (THF- $\alpha$ ), 33.1 (propyl- $\alpha$ ), 25.4 (THF- $\beta$ ), 24.2 (propyl- $\beta$ ), 14.2 (propyl- $\gamma$ ). Anal. Calcd for $\mathrm{C}_{38} \mathrm{H}_{40} \mathrm{O}_{4} \cdot \mathrm{Ti}_{2} \cdot \mathrm{Br}_{4} \bullet\left(\mathrm{C}_{4} \mathrm{H}_{8} \mathrm{O}\right.$ ) $2: \mathrm{C}, 49.32 ; \mathrm{H}$, 5.04. Found: C, 49.12; H,4.49. X-ray crystallography: see Appendix A-8.

## 34: $\mathrm{C}_{38} \mathrm{H}_{40} \mathrm{O}_{4}$ (gem-CpTiCl) $)_{2}$ (geminal up/down)

34

To a solution of tetrakis(2-hydroxy-3-propylphenyl)ethene (7) ( $0.0234 \mathrm{~g}, 0.0414 \mathrm{mmol}$ ) in 1 mL of toluene was added $\mathrm{NaH}(0.0042 \mathrm{~g}, 0.18 \mathrm{mmol})$ suspended in 1 mL of toluene. After stirring the mixture for $2.5 \mathrm{~h}, \mathrm{CpTiCl}_{3}(0.0192 \mathrm{~g}, 0.0876 \mathrm{mmol})$ was added, dissolved in 1 mL of toluene. The color turned orange immediately, then light red. After overnight, the volatiles were removed in vacuo. The residue was triturated with toluene, filtered through a Celite-packed pipette, and the toluene was removed in vacuo. Crystallization from hexane-toluene, cooling from elevated temperature to r.t., then to

Chapter 3 3.4. Experimental page 152
$-30^{\circ} \mathrm{C}$, yielded light orange prism-needle crystals of 34 . The structure was confirmed by X-ray crystallography, although the crystallized material as a bulk still contained impurities, mainly Cp-based species. ${ }^{1} \mathrm{H}$ NMR ( $360 \mathrm{MHz}, \mathrm{C}_{6} \mathrm{D}_{6}$ ): $\delta 8.21(4 \mathrm{H}, \mathrm{dd}, J=7.5$, $1.8 \mathrm{~Hz}), 6.82(4 \mathrm{H}, \mathrm{t}, J=7.5 \mathrm{~Hz}), 6.72(4 \mathrm{H}, \mathrm{dd}, J=7.2,2 \mathrm{~Hz}), 6.18(10 \mathrm{H}, \mathrm{s}, \mathrm{Cp}), 2.83$ $\left(4 \mathrm{H}, \mathrm{m}, \alpha-\mathrm{CH}_{\mathrm{a}}\right), 2.23\left(4 \mathrm{H}, \mathrm{m}, \alpha-\mathrm{CH}_{\mathrm{b}}\right), 1.50\left(8 \mathrm{H}, \mathrm{m}, \beta-\mathrm{CH}_{\mathrm{a}} \mathrm{H}_{\mathrm{b}}\right), 0.78(12 \mathrm{H}, \mathrm{t}, J=7.3 \mathrm{~Hz}$, $\gamma-\mathrm{CH}_{3}$ ). X-ray crystallography: see Appendix A-9.

## 35: $\mathbf{C}_{38} \mathbf{H}_{40} \mathbf{O}_{4}$ (gem-TiBn $)_{2}$ (geminal up/down)

7

35

To a solution of tetrakis(2-hydroxy-3-propylphenyl)ethene (7) ( $0.2004 \mathrm{~g}, 0.3548 \mathrm{mmol}$ ) in toluene ( 4 mL ) was added $\mathrm{TiBn}_{4}(0.3078 \mathrm{~g}, 0.7464 \mathrm{mmol})$ dissolved in 1 to 2 mL toluene. After 30 minutes, the solution was concentrated and cooled to $-30^{\circ} \mathrm{C}$ to produce crystals. By repeating crystallization from toluene-hexanes, more crystals were obtained. All of the crystals were washed with a small amount of hexanes to remove the remaining unreacted reagent. Analytically pure product 35 was obtained as orange-brown crystals ( $0.290 \mathrm{~g}, 66 \%)$. ${ }^{\text {'H NMR ( }} 360 \mathrm{MHz}, \mathrm{C}_{6} \mathrm{D}_{6}$ ): $\boldsymbol{\delta} 7.40\left(4 \mathrm{H}, \mathrm{br} \mathrm{d}, J=7.5 \mathrm{~Hz}, \mathrm{Bn}_{2}\right.$-ortho), 7.31 ( $4 \mathrm{H}, \mathrm{br} \mathrm{t}, J=7.5 \mathrm{~Hz}, \mathrm{Bn}_{\mathrm{a}}-$ meta) , $7.16(4 \mathrm{H}, \mathrm{dd}, J=7,2.2 \mathrm{~Hz}$ ), $7.06(2 \mathrm{H}$, br t, $J=7.5 \mathrm{~Hz}$, $\mathrm{Bn}_{\mathrm{a}}$-para), $6.83\left(4 \mathrm{H}\right.$, br t, $J=7.5 \mathrm{~Hz}, \mathrm{Bn}_{\mathrm{b}}-$ meta $), 6.78(4 \mathrm{H}, \mathrm{dd}, J=7,2.2 \mathrm{~Hz}), 6.75(4 \mathrm{H}, \mathrm{t}$, $J=7 \mathrm{~Hz}), 6.67\left(2 \mathrm{H}\right.$, br $\mathrm{t}, J=7.5 \mathrm{~Hz}, \mathrm{Bn}_{\mathrm{b}}$-para $), 6.51\left(4 \mathrm{H}, \mathrm{br} \mathrm{d}, J=7.5 \mathrm{~Hz}, \mathrm{Bn}_{\mathrm{b}}\right.$-ortho), $3.30\left(4 \mathrm{H}, \mathrm{s}, \mathrm{PhCH}_{2}\right) 2.84\left(4 \mathrm{H}, \mathrm{m}\right.$, propyl- $\alpha-\mathrm{CH}_{2}$ ), $2.34\left(4 \mathrm{H}, \mathrm{s}, \mathrm{PhC}^{\prime} \mathrm{H}_{2}\right), 2.21(4 \mathrm{H}, \mathrm{m}$, propyl $-\alpha-\mathrm{CH}_{\mathrm{b}}$ ), $1.57\left(8 \mathrm{H}, \mathrm{m}\right.$, propyl $\left.-\beta-\mathrm{CH}_{\mathrm{a}} \mathrm{H}_{\mathrm{b}}\right), 0.91\left(12 \mathrm{H}, \mathrm{t}, J=7.2 \mathrm{~Hz}\right.$, propyl $\left.-\gamma-\mathrm{CH}_{3}\right)$. ${ }^{13} \mathrm{C}$ NMR ( $125 \mathrm{MHz}, \mathrm{BB}, \mathrm{C}_{6} \mathrm{D}_{6}$ ): $\delta 159.1,144.5,140.9,139.7,131.5,130.2,130.0,129.1$, 128.6, 128.3, 127.0, 126.9, 125.6, 123.3, 122.1, 84.2, 82.9, 33.1, 23.6, 14.2. Anal. Calcd for $\mathrm{C}_{38} \mathrm{H}_{40} \mathrm{O}_{4} \cdot \mathrm{Ti}_{2} \bullet\left(\mathrm{C}_{7} \mathrm{H}_{7}\right)_{4}: \mathrm{C}, 77.64 ; \mathrm{H}, \mathbf{6 . 7 1}$. Found: $\mathrm{C}, 77.38 ; \mathrm{H}, 6.64$.

## 36: $\left[\left(\mathrm{C}_{38} \mathrm{H}_{40} \mathrm{O}_{4}\right)(\mathrm{TiBn})_{2}(\mu-\mathrm{Bn})\right]\left[\mathrm{BnC}\left(\mathrm{C}_{6} \mathrm{~F}_{5}\right)_{3}\right]$ ?

35

36

NMR-tube reaction. The geminal-up/down di-TiBn $\mathbf{n}_{2}$ complex 35 ( $0.0032 \mathrm{~g}, 0.0031$ $\mathrm{mmol})$ and $\mathrm{B}\left(\mathrm{C}_{6} \mathrm{~F}_{5}\right)_{3}(0.0016 \mathrm{~g}, 0.0031 \mathrm{mmol})$ were dissolved in ca .0 .5 mL of $\mathrm{C}_{6} \mathrm{D}_{6}$. The ${ }^{1} H$ NMR spectrum at 15 minutes after mixing showed broad "intermediate" signals. After a day, the spectrum showed the compound designated as 36 , with a symmetric ( $\mathrm{C}_{2 \mathrm{v}}$ or $\mathrm{C}_{\mathrm{iv}}$ ) ligand framework and 2:1:1 ratio of benzyl groups, as the major product. The structure of 36 is suggested as shown in the equation above, based on the symmetry and the number of different benzyl groups. ${ }^{1} \mathrm{H}$ NMR $\left(360 \mathrm{MHz}, \mathrm{C}_{6} \mathrm{D}_{6}\right): \delta 7.14 \sim 6.99$ (integral not clear due to overlap with contaminant toluene), 6.94~6.81 (integral not clear due to minor impurities), $6.83(4 \mathrm{H}, \mathrm{t}, J=7.5 \mathrm{~Hz}, \mathrm{H}-5$ of ligand framework), $6.69(4 \mathrm{H}, \mathrm{dd}, J=7.5,1.5$ $\mathrm{Hz}, \mathrm{H}-4$ of ligand framework), $3.28\left(4 \mathrm{H}, \mathrm{s}, \mathrm{PhCH}_{2}\right) 2.88\left(2 \mathrm{H}, \mathrm{s}, \mathrm{PhClH}_{2}\right), 2.78(2 \mathrm{H}, \mathrm{s}$, PhC" $\mathrm{H}_{2}$ ), $2.76\left(4 \mathrm{H}, \mathrm{m}\right.$, propyl- $\alpha-\mathrm{CH}_{2}$ ), $2.40\left(4 \mathrm{H}, \mathrm{m}\right.$, propyl $\left.-\alpha-\mathrm{CH}_{\mathrm{b}}\right), 1.59(8 \mathrm{H}, \mathrm{m}$, propyl-$\left.\beta-\mathrm{CH}_{2} \mathrm{H}_{\mathrm{b}}\right), 0.88\left(12 \mathrm{H}, \mathrm{t}, \mathrm{J}=7 \sim 7.5 \mathrm{~Hz}\right.$, propyl $\left.-\gamma-\mathrm{CH}_{3}\right)$.
Attempts to crystallize. The above-mentioned reaction was repeated using $35(0.0688 \mathrm{~g}$, $0.0674 \mathrm{mmol})$ and $\mathrm{B}\left(\mathrm{C}_{6} \mathrm{~F}_{5}\right)_{3}(0.0345 \mathrm{~g}, 0.0674 \mathrm{mmol})$ in 2.5 mL toluene, under conditions free of THF and ether. Crystallization from toluene (r.t. to $-30^{\circ} \mathrm{C}$ ) or THF-toluene was not successful. The use of THF as a crystallization solvent resulted in the polymerization of THF.
Polymerization of THF by 36. In one of the crystallization attempts for 36, a solution of 36 (unknown amount) in THF was prepared, concentrated, a few drops of toluene was added to it, and cooled to $-30^{\circ} \mathrm{C}$. After overnight, the mixture had become two layers: a dark layer and a viscous colorless layer. A few more drops of THF was added to dilute the dark layer and the mixture was left at r.t.. Next day, the colorless viscous layer increased. It is thus tentatively concluded that THF was polymerized.

## 37: $\mathrm{C}_{36} \mathrm{H}_{40} \mathrm{O}_{4} \cdot \mathrm{Al}_{3} \cdot \mathbf{M e}_{5}$

7

37

To a solution of tetrakis(2-hydroxy-3-propylphenyl)ethylene (7) ( $0.0386 \mathrm{~g}, 0.0683 \mathrm{mmol}$ ) in 1 mL of toluene was added $\mathrm{Me}_{3} \mathrm{Al}(0.0207 \mathrm{~g}, 0.287 \mathrm{mmol})$ dissolved in 1 mL of toluene. The color turned slightly yellow immediately and gas evolution was observed. After 5 min . of stirring, the volatiles were removed in vacuo. The residue did not redissolve in toluene, thus the mixture was filtered and the filtrate was concentrated. ${ }^{g}$ Adding pentane to the oily solution and cooling to $-30^{\circ} \mathrm{C}$ yielded crystals. After removal of the mother liquor, rinsing with small amount of cold pentane, and drying under reduced pressure, the analytically pure product was obtained ( $0.0243 \mathrm{~g}, 50 \%$ ). ${ }^{1} \mathrm{H}$ NMR ( $360 \mathrm{MHz}, \mathrm{C}_{6} \mathrm{D}_{6}$ ): $\boldsymbol{\delta} 7.24$ ( $\mathrm{lH}, \mathrm{dd}, J=7.2,2 \mathrm{~Hz}$ ), $7.09(1 \mathrm{H}, \mathrm{dd}, J=6,3.5 \mathrm{~Hz}), 6.91 \sim 6.87$ (3H, overlapping), $6.81(1 \mathrm{H}, \mathrm{dd}, J=5.5,3.8 \mathrm{~Hz}), 6.70(1 \mathrm{H}, \mathrm{dd}, J=7.5,2 \mathrm{~Hz}), 6.65 \sim 6.58$ ( 5 H , overlapping), $2.90(1 \mathrm{H}, \mathrm{m}$, propyl- $\alpha-\mathrm{CH}$ ), $2.73(1 \mathrm{H}, \mathrm{m}$, propyl $-\alpha-\mathrm{CH}), 2.63(1 \mathrm{H}, \mathrm{m}$, propyl- $\alpha-\mathrm{CH}$ ), $2.43 \sim 2.31(5 \mathrm{H}$, overlapping, propyl $-\alpha-\mathrm{CH}$ ), $1.63 \sim 1.41$ ( 8 H , overlapping, propyl- $\beta-\mathrm{CH}), 0.92\left(3 \mathrm{H}, \mathrm{t}, J=7.3 \mathrm{~Hz}\right.$, propyl $\left.-\gamma-\mathrm{CH}_{3}\right), 0.89(3 \mathrm{H}, \mathrm{t}, J=7.3 \mathrm{~Hz}$, propyl- $\boldsymbol{\gamma}$ $\left.\mathrm{CH}_{3}\right), 0.84\left(3 \mathrm{H}, \mathrm{t}, J=7.3 \mathrm{~Hz}\right.$, propyl- $\left.\gamma-\mathrm{CH}_{3}\right), 0.75\left(3 \mathrm{H}, \mathrm{t}, J=7.3 \mathrm{~Hz}\right.$, propyl- $\left.\gamma-\mathrm{CH}_{3}\right), 0.26$ $\left(1 \mathrm{H}, \mathrm{s}, \mathrm{AlCH}_{3}\right), 0.21\left(1 \mathrm{H}, \mathrm{s}, \mathrm{AlCH}_{3}\right), 0.12\left(1 \mathrm{H}, \mathrm{s}, \mathrm{AlCH}_{3}\right),-1.42\left(1 \mathrm{H}, \mathrm{s}, \mathrm{AlCH}_{3}\right),-1.46$ ( $1 \mathrm{H}, \mathrm{s}, \mathrm{AlCH}_{3}$ ). ${ }^{13} \mathrm{C}$ NMR ( $125 \mathrm{MHz}, \mathrm{BB}, \mathrm{C}_{6} \mathrm{D}_{6}$ ): $\delta 153.1,149.4,149.2,148.6,142.9$, 140.9, 136.2, 136.1, 134.6, 134.2, 133.3, 132.7, 132.1, 131.3, 129.9, 129.7, 129.5, 129.4, $129.2,128.3,128.1,126.0,125.1,124.84,123.79,118.7,34.2$ (propyl- $\alpha$ ), 32.9 (propyl- $\alpha$, two signals overlapping), 32.6 (propyl- $\alpha$ ), 23.8 (propyl- $\beta$ ), 23.4 (propyl- $\beta$ ), 22.9 (propyl$\beta$ ), 21.9 (propyl- $\beta$ ), 14.22 (propyl- ), 14.15 (propyl- $\boldsymbol{\gamma}$ ), 14.0 (propyl- ), 13.9 (propyl- $\gamma$ ), $-5.7\left(\mathrm{AlCH}_{3}\right),-6.7\left(\mathrm{AlCH}_{3}\right),-10.1\left(\mathrm{AlCH}_{3}\right),-10.2\left(\mathrm{AlCH}_{3}\right),-11.2\left(\mathrm{AlCH}_{3}\right)$. Anal. Calcd for $\mathrm{C}_{48} \mathrm{H}_{65} \mathrm{Al}_{3} \mathrm{O}_{4}$ : C, 73.26; $\mathrm{H}, 8.33$. Found: $\mathrm{C}, 73.39 ; \mathrm{H}, 8.33$.

[^10]Formation of "A": THF-driven abstraction of $\mathrm{Me}_{3} \mathrm{Al}$ from 37.

37

A

A solution of complex 37 (undetermined amount) in THF- $d_{8}$ was prepared in an NMR tube. The ${ }^{1} H$ NMR spectrum at 15 minutes after preparation showed a single aromatic ring for the ligand framework, accompanied by two identical deshielded methyl groups. The spectrum remained unchanged after 2 days. One molecule of $\mathrm{Me}_{3} \mathrm{Al}$ was freed from the complex: the identity of the liberated $\mathrm{Me}_{3} \mathrm{Al}$ was confirmed by adding small amount of $\mathrm{Me}_{3} \mathrm{Al}$ to the solution and observing an increase in the intensity of the signal assigned to the liberated $\mathrm{Me}_{3} \mathrm{Al}$. ${ }^{1} \mathrm{H}$ NMR ( $300 \mathrm{MHz}, \mathrm{THF}-\mathrm{d}_{8}$ ): $\delta 7.07(4 \mathrm{H}, \mathrm{dd}, J=7.3,1.5 \mathrm{~Hz}$ ), $6.62(4 \mathrm{H}, \mathrm{dd}, J=7.3,1.5 \mathrm{~Hz}), 6.32(4 \mathrm{H}, \mathrm{t}, J=7.3 \mathrm{~Hz}), 2.64\left(4 \mathrm{H}, \mathrm{m}\right.$, propyl- $\left.\alpha-\mathrm{CH}_{2}\right), 2.17$ ( $4 \mathrm{H}, \mathrm{m}$, propyl- $\alpha-\mathrm{CH}_{\mathrm{b}}$ ), $1.42\left(8 \mathrm{H}, \mathrm{m}\right.$, propyl $\left.-\beta-\mathrm{CH}_{2} \mathrm{H}_{\mathrm{b}}\right), 0.77(12 \mathrm{H}, \mathrm{t}, J=7.3 \mathrm{~Hz}$, propyl-$\left.\gamma-\mathrm{CH}_{3}\right),-0.35\left(6 \mathrm{H}, \mathrm{s}, \mathrm{AlCH}_{3}\right),-0.94\left(9 \mathrm{H}, \mathrm{s}\right.$, freed $\left.\mathrm{Me}_{3} \mathrm{Al}\right) .{ }^{13} \mathrm{C} \mathrm{NMR}\left(100 \mathrm{MHz}\right.$, THF-d ${ }_{8}$ ): $\delta 155.0,142.5,133.1,130.6,128.32,128.31,117.5,34.1$ (propyl- $\alpha$ ), 23.9 (propyl- $\beta$ ), 14.4 (propyl- $\gamma$ ), $-9.1\left(\mathrm{AlCH}_{3}\right.$, of freed $\left.\mathrm{Me}_{3} \mathrm{Al}\right),-13.3\left(\mathrm{AlCH}_{3}\right.$, of $\left.\mathbf{A}\right)$. The structure of $\mathbf{A}$ is suggested by these spectroscopic features.

38: $\mathrm{C}_{\mathbf{3 8}} \mathbf{H}_{40} \mathrm{O}_{\mathbf{4}} \cdot \mathrm{Al}_{\mathbf{3}} \cdot \mathbf{E t}_{\mathbf{5}}$

7

38

To a solution of tetrakis(2-hydroxy-3-propylphenyl)ethene (7) ( $0.0595 \mathrm{~g}, 0.105 \mathrm{mmol}$ ) in 1 mL of toluene was added a solution of $\mathrm{Et}_{3} \mathrm{Al}$ in toluene $(1.105 \mathrm{mmol} / \mathrm{mL}, 0.42 \mathrm{~mL}, 0.46$ mmol ) slowly. The color turned slightly yellow immediately and gas evolution was

Chapter 3 3.4. Experimental page 156
observed. After 5 min . of stirring, the volatiles were removed in vacuo, and the residue was crystallized from benzene (r.t., slow evaporation). The crystals, which were separated from the mother liquor, washed with hexanes, and dried in vacuo, were analytically pure product $38(0.0503 \mathrm{~g}, 61 \%)$. The structure was confirmed by X-ray crystallography. The residue from the mother liquor after evaporation was also mainly the product, accompanied by unreacted $\mathrm{Et}_{3} \mathrm{Al}$. ${ }^{1} \mathrm{H}$ NMR ( $360 \mathrm{MHz}, \mathrm{C}_{6} \mathrm{D}_{6}$ ): $\boldsymbol{\delta 7 . 2 5 ( 1 H , ~ d d , ~}$ $J=5.5,4 \mathrm{~Hz}), 7.08(1 \mathrm{H}, \mathrm{dd}, J=6.5,2.8 \mathrm{~Hz}), 6.94(2 \mathrm{H}$, overlapping), $6.85(1 \mathrm{H}, \mathrm{dd}, J=$ $7.5,2 \mathrm{~Hz}), 6.79(\mathrm{HH}, \mathrm{dd}, J=5.5,3.5 \mathrm{~Hz}), 6.69(1 \mathrm{H}, \mathrm{dd}, J=7.5,2 \mathrm{~Hz}), 6.65(3 \mathrm{H}$, overlapping), $6.59\left(2 \mathrm{H}\right.$, overlapping), $3.03\left(1 \mathrm{H}, \mathrm{m}\right.$, propyl- $\left.\alpha-\mathrm{CH}_{2}\right), 2.92(1 \mathrm{H}, \mathrm{m}$, propyl-$\alpha-\mathrm{CH}), 2.69\left(2 \mathrm{H}\right.$, overlapping m , propyl- $\left.\alpha-\mathrm{CH}^{\prime} \mathrm{s}\right), 2.43(4 \mathrm{H}$, overlapping m, propyl- $\alpha-$ CH's), $1.66\left(3 \mathrm{H}, \mathrm{t}, \mathrm{J}=8.2 \mathrm{~Hz}\right.$, axial- $\mathrm{AlCH}_{2} \mathrm{CH}_{3}$ ), $1.56 \sim 1.53$ ( 4 H , overlapping m, propyl-$\beta$-CH's), $1.53\left(3 \mathrm{H}, \mathrm{t}, J=8.2 \mathrm{~Hz}\right.$, axial- $\left.\mathrm{AlCH}_{2} \mathrm{CH}_{3}\right), 1.52(3 \mathrm{H}, \mathrm{t}, J=8.2 \mathrm{~Hz}$, axial$\left.\mathrm{AlCH}_{2} \mathrm{CH}_{3}\right), 1.40\left(4 \mathrm{H}\right.$, overlapping m, propyl- $\left.\beta-\mathrm{CH}^{\prime} \mathrm{s}\right), 0.97 \sim 0.86(2 \mathrm{H}+2 \mathrm{H}+2 \mathrm{H}$, overlapping m, axial- $\left.\mathrm{AlCH}_{2} \mathrm{CH}_{3}\right), 0.97\left(3 \mathrm{H}, \mathrm{t}, \mathrm{J}=7 \mathrm{~Hz}\right.$, propyl- $\left.\gamma-\mathrm{CH}_{3}\right), 0.95(3 \mathrm{H}, \mathrm{t}, \mathrm{J}=7$ Hz , propyl- $\left.\gamma-\mathrm{CH}_{3}\right), 0.93\left(3 \mathrm{H}, \mathrm{t}, J=7 \mathrm{~Hz}\right.$, propyl $\left.-\gamma-\mathrm{CH}_{3}\right), 0.79\left(2 \mathrm{H}, \mathrm{m}\right.$, axial- $\left.\mathrm{AlCH}_{2} \mathrm{CH}_{3}\right)$, $0.78\left(3 \mathrm{H}, \mathrm{t}, J=7 \mathrm{~Hz}\right.$, propyl- $\left.\gamma-\mathrm{CH}_{3}\right), 0.46\left(3 \mathrm{H}, \mathrm{t}, J=8 \mathrm{~Hz}\right.$, equatorial- $\left.\mathrm{AlCH}_{2} \mathrm{CH}_{3}\right), 0.08$ $\left(3 \mathrm{H}, \mathrm{t}, J=7.8 \mathrm{~Hz}\right.$, equatorial- $\left.\mathrm{AlCH}_{2} \mathrm{CH}_{3}\right),-0.56\left(1 \mathrm{H}, \mathrm{m}\right.$, equatorial- $\left.\mathrm{AlCH}_{2} \mathrm{CH}_{3}\right),-0.68$

Calcd for $\mathrm{C}_{48} \mathrm{H}_{65} \mathrm{Al}_{3} \mathrm{O}_{4}$ : $\mathrm{C}, 73.26 ; \mathrm{H}, 8.33$. Found: $\mathrm{C}, 73.39 ; \mathrm{H}, 8.33$. X-ray crystallography: see Appendix A-11.

## C: $\mathrm{C}_{38} \mathrm{H}_{40} \mathrm{O}_{4}(\mathbf{( A l E t C l})_{4}$

7

C

Chapter 3 3.4. Experimental page 157

To a solution of tetrakis(2-hydroxy-3-propylphenyl)ethene (7) ( $0.0716 \mathrm{~g}, 0.127 \mathrm{mmol}$ ) in 1 mL of toluene was slowly added $\mathrm{Et}_{2} \mathrm{AlCl}(0.0629 \mathrm{~g}, 0.522 \mathrm{mmol})$ diluted with total of 2.5 mL toluene. The color immediately turned slightly yellow, then reddish orange, accompanied by gas evolution. After overnight, the color became pale yellow. After removal of the volatiles in vacuo, the product was crystallized from toluene (warm $\rightarrow$ r.t.). After tiny shiny crystals were formed, some hexanes was layered on for slow diffusion. Later more hexanes was added and cooled to $-30^{\circ} \mathrm{C}$ for several days. The mother liquor was removed from the crystals, which were washed with pentane and dried in vacuo. The yield was 0.0534 g ( $45 \%$ ). The ${ }^{1} \mathrm{H}$ NMR spectrum in $\mathrm{C}_{6} \mathrm{D}_{6}$ was complicated, probably of a mixture of isomers. Anal. Calcd for $\mathrm{C}_{38} \mathrm{H}_{40} \mathrm{O}_{4} \cdot\left(\mathrm{AlC}_{2} \mathrm{H}_{5} \mathrm{Cl}\right)_{4}: \mathrm{C}$, $59.62 ; \mathrm{H}, 6.53 ; \mathrm{Cl}, 15.30$. Found: C, $59.72 ; \mathrm{H}, 6.30 ; \mathrm{Cl}, 14.59$.

## D and E: THF-driven abstraction of aluminum from C

NMR-tube reaction. The product $\mathbf{C}$ from the previous reaction (amount unrecorded) was dissolved in THF-d ${ }_{8}$, placed in an NMR-tube, and the ${ }^{1} H$ NMR spectrum was taken immediately after preparation of the sample. A symmetrical complex $\mathbf{D}$ with liberated aluminum, presumably $\mathrm{EtAlCl}_{2}$ (2 equiv.), was observed. After overnight, the same solution showed a mixture of $\mathbf{D}$ and a newly emerging unsymmetrical species $\mathbf{E}$.
Isolation of $\mathbf{E}$. The product $\mathbf{E}$ was exclusively obtained by mixing tetrakis(2-hydroxy-3propylphenyl)ethene (7) ( $0.0558 \mathrm{~g}, 0.0988 \mathrm{mmol}$ ) and $\mathrm{Et}_{2} \mathrm{AlCl}(0.0496 \mathrm{~g}, 0.411 \mathrm{mmol})$ in THF ( 2 mL ) for a day. After removal of the volatiles in vacuo, ${ }^{1} \mathrm{H}$ NMR spectroscopy of the remaining viscous pale yellow oil in $\mathrm{C}_{6} \mathrm{D}_{6}$ showed clean $\sigma$-symmetry compound E . The THF- $\mathrm{d}_{\mathrm{g}}$ solution of $\mathbf{E}$ showed a complicated spectrum, probably a mixture of at least two compounds. At least one of them is unsymmetrical.
D. 'H NMR ( $360 \mathrm{MHz}, \mathrm{THF}-\mathrm{d}_{8}$ ): $\delta \mathbf{7 . 0 9}(\mathbf{4 H}, \mathrm{dd}, J=7.5,2 \mathrm{~Hz}), 6.60(4 \mathrm{H}, \mathrm{dd}, J=7.5,2$ $\mathrm{Hz}), 6.32(4 \mathrm{H}, \mathrm{t}, J=7.5 \mathrm{~Hz}), 2.63\left(4 \mathrm{H}, \mathrm{m}\right.$, propyl $\left.-\alpha-\mathrm{CH}_{3}\right), 2.14\left(4 \mathrm{H}, \mathrm{m}\right.$, propyl $\left.-\alpha-\mathrm{CH}_{\mathrm{b}}\right)$, $1.42\left(8 \mathrm{H}, \mathrm{m}\right.$, propyl $\left.-\beta-\mathrm{CH}_{2} \mathrm{H}_{\mathrm{b}}\right), 1.30\left(6 \mathrm{H}, \mathrm{t}, J=8 \mathrm{~Hz}, \mathrm{AlCH}_{2} \mathrm{CH}_{3}\right), 0.75(12 \mathrm{H}, \mathrm{t}, J=7.3$ $\mathrm{Hz}), 0.40\left(4 \mathrm{H}, \mathrm{q}, J=8 \mathrm{~Hz}, \mathrm{AlCH}_{2} \mathrm{CH}_{3}\right)$. The liberated aluminum is presumed to be

EtAlCl $2: 1.03\left(6 \mathrm{H}\right.$, slightly br $\left.\mathrm{t}, J=8 \mathrm{~Hz}, \mathrm{AlCH}_{2} \mathrm{CH}_{3}\right), 0.07(4 \mathrm{H}$, slightly br $\mathrm{q}, J=8 \mathrm{~Hz}$, $\mathrm{AlCH}_{2} \mathrm{CH}_{3}$ ).
E. ${ }^{1} \mathrm{H}$ NMR ( $360 \mathrm{MHz}, \mathrm{C}_{6} \mathrm{D}_{6}$ ): $\delta 7.09$ ( 2 H , dd, $J=7.3,1.8 \mathrm{~Hz}$ ), $6.99(2 \mathrm{H}, \mathrm{dd}, J=7.3,1.8$ $\mathrm{Hz}), 6.80(2 \mathrm{H}, \mathrm{dd}, J=7.3,1.8 \mathrm{~Hz}), 6.76(2 \mathrm{H}, \mathrm{dd}, J=7.3,1.8 \mathrm{~Hz}), 6.66(2 \mathrm{H}, \mathrm{t}, J=7.3$ $\mathrm{Hz}), 6.61(2 \mathrm{H}, \mathrm{t}, J=7.3 \mathrm{~Hz}), 4.74(4 \mathrm{H}, \mathrm{m}, \mathrm{THF}-\alpha), 2.81(2 \mathrm{H}, \mathrm{m}$, propyl $-\alpha-\mathrm{CH})$, $2.56 \sim 2.46(6 \mathrm{H}, \mathrm{m}$, propyl $-\alpha-\mathrm{CH}), 1.69\left(4 \mathrm{H}, \mathrm{m}\right.$, propyl $\left.-\beta-\mathrm{CH}_{2} \mathrm{H}_{\mathrm{b}}\right), 1.53 \sim 1.51(4 \mathrm{H}+4 \mathrm{H}, \mathrm{m}$, propyl- $\beta-\mathrm{C}^{2} \mathrm{H}_{3} \mathrm{H}_{\mathrm{b}}$ plus THF- $\beta$ ), $1.28\left(3 \mathrm{H}, \mathrm{t}, J=8 \mathrm{~Hz}\right.$, axial $\left.\mathrm{AlCH}_{2} \mathrm{CH}_{3}\right), 0.97(6 \mathrm{H}, \mathrm{t}, J=$ $7.3 \mathrm{~Hz}), 0.84(6 \mathrm{H}, \mathrm{t}, J=7.3 \mathrm{~Hz}), 0.67\left(3 \mathrm{H}, \mathrm{t}, J=8 \mathrm{~Hz}\right.$, equatorial $\left.\mathrm{AlCH}_{2} \mathrm{CH}_{3}\right), 0.29(3 \mathrm{H}$, $t, J=8 \mathrm{~Hz}$, axial $\left.\mathrm{AlCH}_{2} \mathrm{CH}_{3}\right), \mathbf{0} .35\left(3 \mathrm{H}, \mathrm{t}, J=8 \mathrm{~Hz}\right.$, equatorial $\left.\mathrm{AlCH}_{2} \mathrm{CH}_{3}\right)$. The liberated aluminum is presumed to be $\mathrm{EtAlCl}_{2}\left(\right.$ thf): $1.36\left(6 \mathrm{H}, \mathrm{t}, J=8 \mathrm{~Hz}, \mathrm{AlCH}_{2} \mathrm{CH}_{3}\right)$, $0.24\left(4 \mathrm{H}, \mathrm{q}, J=8 \mathrm{~Hz}, \mathrm{AlCH}_{2} \mathrm{CH}_{3}\right)$; the coordinated THF molecule exchanges with free excess THF: $3.45(14 \sim 15 H, \alpha), 0.99(14 \sim 15 H, \beta) .{ }^{13} \mathrm{C}$ NMR ( $50 \mathrm{MHz}, \mathrm{BB}, \mathrm{C}_{6} \mathrm{D}_{6}$ ): $\delta$ $154.9,150.0,133.2,132.0,130.1,130.0,129.1,128.8,128.3,123.9,123.5,123.14(?)$, $113.0,73.9$ (coordinated THF- $\alpha$ ), 71.1 (excess THF- $\alpha$ ), 33.7 (propyl- $\alpha$ ), 33.0 (propyl- $\alpha$ ), 25.2 (coordinated THF- $\beta$ ), 24.8 (excess THF- $\beta$ ), 23.1 (propyl- $\beta$ ), 22.9 (propyl- $\beta$ ), 14.3 (propyl- $\gamma$ ), 14.2 (propyl- $\gamma$ ), $9.2\left(\mathrm{AlCH}_{2} \mathrm{CH}_{3}\right.$, liberated $\mathrm{EtAlCl}_{2}$ ?), $8.5\left(\mathrm{AlCH}_{2} \mathrm{CH}_{3}\right.$, axial?), $8.0\left(\mathrm{AlCH}_{2} \mathrm{CH}_{3}\right.$, equatorial?); " $\mathrm{AlCH} \mathrm{CH}_{3}$ " signals are not clearly observed, probably due to broadening.

## $\mathrm{F}: \mathrm{C}_{38} \mathrm{H}_{40} \mathrm{O}_{4} \cdot\left(\mathrm{AlCl}_{2}\right)_{4}$

To a solution of tetrakis(2-hydroxy-3-propylphenyl)ethene (7) ( $0.1558 \mathrm{~g}, 0.2759 \mathrm{mmol}$ ) in 1.5 mL of toluene was added $\mathrm{EtAlCl}_{2}(0.1499 \mathrm{~g}, 1.181 \mathrm{mmol})$ dissolved in 2 mL of toluene. The color turned dark immediately, with gas evolution. The color soon turned greenish, and became lighter as the mixture became cloudy. After overnight, the milky light orange-brown precipitate was collected, washed with toluene followed by pentane, and dried in vacuo to give the off-white, slightly pink powder $\mathbf{F}$ ( $0.1995 \mathrm{~g}, 76 \%$ ). Anal. Calcd for $\mathrm{C}_{38} \mathrm{H}_{40} \mathrm{O}_{4} \mathrm{Al}_{4} \mathrm{Cl}_{8}$ : C, 47.93; $\mathrm{H}, 4.23 ; \mathrm{Cl}, 29.78$. Found: C, $48.57 ; \mathrm{H}, 4.36 ; \mathrm{Cl}$, 28.02.

## G/H and 39: THF-driven abstraction of aluminum reagent(s) from $F$

NMR-tube reaction. A solution of $\mathbf{F}$ (amount unrecorded) in THF-d $\mathrm{d}_{8}$ was prepared in an NMR tube. The 'H NMR spectrum immediately after the preparation of the sample showed a $\sigma$-symmetry species $\mathbf{G}$ and a broad, intermediate set of signals (H) in a ratio of ca. 1.5~2 : 1. After overnight, the same solution showed a complicated spectrum of probably a mixture of at least two compounds.
Isolation of 39. Tetrakis(2-hydroxy-3-propylphenyl)ethene (7) ( $0.0551 \mathrm{~g}, 0.0975 \mathrm{mmol}$ ) and $\mathrm{EtAlCl}_{2}$ ( $0.0514 \mathrm{~g}, 0.405 \mathrm{mmol}$ ) were mixed in THF ( 2 mL ) for a day. After removal of the volatiles in vacuo, the pale orange crude product 39 showed a ${ }^{\prime} H$ NMR spectrum in THF-d ${ }_{8}$ identical to the above-mentioned complicated spectrum. The crude product was crystallized from toluene (r.t. $\rightarrow-30^{\circ} \mathrm{C}$ ), growing tiny shiny less-colored crystals. The crystals were further grown by layering pentane on to allow slow diffusion at $-30^{\circ} \mathrm{C}$, producing pale orange prism crystals that were used to obtain the X-ray crystallographic structure of 39 (Appendix A-12). The prisms, along with an orange-colored and lesscrystalline solid, were isolated from the mother liquor, washed with a small amount of pentane and dried in vacuo $(0.0790 \mathrm{~g})$. The mass of the isolated material is larger than a quantitative yield of 39 ( 0.0790 g expected), most likely because the less crystalline part contains inorganic byproduct $\mathrm{AlCl}_{3}(\text { thf })_{n}$, or $\left[\mathrm{AlCl}_{2}\left(\mathrm{thf}_{4}\right]\left[\mathrm{AlCl}_{4}\right]\right.$.
G. 'H NMR ( 360 MHz, THF- $\mathrm{d}_{8}$, tentatively assigned): $\delta 6.97$ ( $2 \mathrm{H}, \mathrm{dd}, \mathrm{J}=7.5,1.5 \mathrm{~Hz}$ ), 6.90 ? ( 2 H , br d, $\mathrm{J}=\sim 7 \mathrm{~Hz}$ ), $6.81(2 \mathrm{H}, \mathrm{br} \mathrm{d}, \mathrm{J}=\sim 7 \mathrm{~Hz}), 6.74(2 \mathrm{H}$, slightly br dd, $\mathrm{J}=\sim 7$, $\sim 1 \mathrm{~Hz}), 6.51(2 \mathrm{H}, \mathrm{t}, \mathrm{J}=7.5 \mathrm{~Hz}), 6.51(2 \mathrm{H}, \mathrm{t}, \mathrm{J}=7.5 \mathrm{~Hz}), 2.73(2 \mathrm{H}, \mathrm{m}$, propyl $-\alpha-\mathrm{CH})$, $2.44(2 \mathrm{H}+2 \mathrm{H}, \mathrm{m}$, propyl- $\alpha-\mathrm{CH}$ ), $2.13(2 \mathrm{H}, \mathrm{m}$, propyl, propyl- $\alpha-\mathrm{CH}), 1.44(4 \mathrm{H}, \mathrm{m}$, propyl $\left.-\beta-\mathrm{CH}_{2} \mathrm{H}_{\mathrm{b}}\right), \mathrm{l} .26\left(4 \mathrm{H}, \mathrm{m}\right.$, propyl, $\left.\beta-\mathrm{CH}_{2} \mathrm{H}_{\mathrm{b}}\right), 0.78\left(6 \mathrm{H}, \mathrm{t}, \mathrm{J}=7.3 \mathrm{~Hz}\right.$, propyl $\left.-\gamma-\mathrm{CH}_{3}\right)$, $0.78\left(6 \mathrm{H}, \mathrm{t}, \mathrm{J}=7.5 \mathrm{~Hz}\right.$, propyl $\left.-\gamma-\mathrm{CH}_{3}\right)$.
H. 'H NMR ( 360 MHz, THF- $d_{8}$, tentatively assigned as $\sigma$-symmetry species with broad signals): $\delta 7.03(2 H, b r), 6.81(2 H, b r), 6.71(4 H, b r), 6.59(2 H, b r t, J=\sim 7.5 \mathrm{~Hz}), 6.46$ ( $2 \mathrm{H}, \mathrm{br}$ ), $2.50 \sim 2.44$ ( 8 H ?, br, propyl- $\alpha-\mathrm{CH}$ ), $1.60 \sim 1.44$ ( 8 H ?, br, propyl- $\beta-\mathrm{CH}$ ), 0.87 ( 12 H ?, br t, overlapping? $J=\sim 7 \mathrm{~Hz}$, propyl $-\gamma-\mathrm{CH}_{3}$ )

Chapter 3 3.4. Experimental page 160
39. ${ }^{1} \mathrm{H}$ NMR ( $360 \mathrm{MHz}, \mathrm{C}_{6} \mathrm{D}_{6}$ ): $\boldsymbol{\delta} \mathbf{- 7 . 1 4}$ ? ( $\mathbf{2 H}$, br, overlapping with solvent signal), 7.09 ( $2 \mathrm{H}, \mathrm{br} \mathrm{d}, \mathrm{J}=7 \sim 8 \mathrm{~Hz}$ ), $6.83(2 \mathrm{H}, \mathrm{dd}, \mathrm{J}=7.5,1.8 \mathrm{~Hz}), 6.71(2 \mathrm{H}, \mathrm{t}, \mathrm{J}=7.3 \mathrm{~Hz}), 6.64(2 \mathrm{H}, \mathrm{J}$ $=7.5,1.8 \mathrm{~Hz}$ ), one aromatic dd $(2 \mathrm{H})$ is not located due to the overlapping; $2.75(4 \mathrm{H}, \mathrm{m}$, propyl- $\alpha-\mathrm{CH}$ ), $2.51(2 \mathrm{H}, \mathrm{m}$, propyl- $\alpha-\mathrm{CH}), 2.40(2 \mathrm{H}, \mathrm{m}$, propyl $-\alpha-\mathrm{CH}), 1.62(4 \mathrm{H}, \mathrm{m}$, propyl- $\left.\beta-\mathrm{CH}_{\mathbf{a}} \mathrm{H}_{\mathrm{b}}\right), 1.49\left(4 \mathrm{H}, \mathrm{m}\right.$, propyl $\left.-\beta-\mathrm{C}^{\prime} \mathrm{H}_{2} \mathrm{H}_{\mathrm{b}}\right), 0.92\left(6 \mathrm{H}, \mathrm{t}, J=7.3 \mathrm{~Hz}\right.$, propyl $\left.-\gamma-\mathrm{CH}_{3}\right)$, $0.78\left(6 \mathrm{H}, \mathrm{t}, J=7.3 \mathrm{~Hz}\right.$, propyl- $\gamma-\mathrm{CH}_{3}$ ). MS (ES) $m / z$ : Calcd for $\mathrm{C}_{42} \mathrm{H}_{48} \mathrm{Al}_{2} \mathrm{Cl}_{2} \mathrm{O}_{5}: 756.25$. Found: 863 ( $88 \%$, unidentified parent signal with $\mathrm{Cl}_{2}$ pattern). X-ray crystallography: see Appendix A-12.

40: $\left(\mathrm{C}_{\mathbf{3 8}} \mathrm{H}_{40} \mathrm{O}_{4} \cdot \mathrm{Na}_{4} \bullet\left(\mathrm{C}_{7} \mathrm{H}_{\mathbf{8}}\right)_{\mathbf{1 2}}\right.$

7

40

To a solution of tetrakis(3-propyl-2-hydroxyphenyl)ethene (7) ( $0.1106 \mathrm{~g}, 0.1958 \mathrm{mmol}$ ) in toluene ( 2 mL ), was added $\mathrm{NaH}(0.0191 \mathrm{~g}, 0.796 \mathrm{mmol}$ ) suspended in 0.5 mL of toluene and the mixture was stirred overnight. The greenish yellow mixture was filtered through Celite-packed pipette. After removal of the volatiles from the filtrate, the crude yield was 0.148 g ( $108 \%$ ). The ${ }^{1} \mathrm{H}$ NMR spectrum in $\mathrm{C}_{6} \mathrm{D}_{6}$ showed a set of broad signals. After crystallization from toluene, pale greenish-yellow crystals were obtained (yield not recorded). ${ }^{1} \mathrm{H}$ NMR ( $360 \mathrm{MHz}, \mathrm{C}_{6} \mathrm{D}_{6}$ ): $\delta 7.332(4 \mathrm{H}, \mathrm{br}), 6.81(4 \mathrm{H}, \mathrm{br}), 6.53(4 \mathrm{H}, \mathrm{br}), 2.21$ $\left(8 \mathrm{H}, \mathrm{br}, \alpha-\mathrm{CH}_{2}\right), 1.39\left(8 \mathrm{H}, \mathrm{br}, \beta-\mathrm{CH}_{2}\right), 0.70\left(12 \mathrm{H}, \mathrm{br}, \gamma-\mathrm{CH}_{2}\right)$. Anal. Calcd for $\mathrm{C}_{38} \mathrm{H}_{40} \mathrm{O}_{4} \bullet \mathrm{Na}_{4}: \mathrm{C}, 69.93 ; \mathrm{H}, 6.18$. Calcd for $\mathrm{C}_{38} \mathrm{H}_{40} \mathrm{O}_{4} \bullet \mathrm{Na}_{4} \bullet\left(\mathrm{C}_{7} \mathrm{H}_{8}\right)_{1 / 2}: \mathrm{C}, 71.33 ; \mathrm{H}, 6.35$. Found: C,71.14; H, 6.33. X-ray crystallography: a trimer structure (see Section 3.1.4) was provided, but data were not refined due to the large residual factor.

## 41: $\mathrm{C}_{3} \mathrm{H}_{4} \mathrm{O}_{4}$ ( $\left.\mathrm{AlEt} \mathrm{t}_{2}\right) \cdot[\mathrm{Mg}(\mathrm{thf})] \cdot[\mathrm{MgCl}($ (hf $)]$

25

41

To a suspension of 25 (FW $=920.4$ based on the elemental analysis, $0.1995 \mathrm{~g}, 0.2168$ $\mathrm{mmol})$ in 3 mL of toluene was added $\mathrm{Et}_{2} \mathrm{AlCl}(0.0261 \mathrm{~g}, 0.216 \mathrm{mmol})$ dissolved in 3.5 mL of toluene. After 15 min . of stirring, the volatiles were removed from the mixture, the residue was triturated with toluene, filtered, and the filtrate was evaporated. Crystallization of the residue from toluene-pentane (slow mixing, r.t. $\rightarrow-30^{\circ} \mathrm{C}$ ) produced large ( $1 \sim 2 \mathrm{~mm}$ ) block crystals among some powdery precipitate. The block crystals, after isolation, washing with pentane, and drying in vacuo for $>2 \mathrm{~h}$, were found to be analytically pure ( $0.0856 \mathrm{~g}, 45 \%$ ). A second crystallization from the residue yielded a less pure portion of the product $(0.0534 \mathrm{~g}, 28 \%)$. The structure was confirmed by X-ray crystallography. ${ }^{1} \mathrm{H}$ NMR ( $360 \mathrm{MHz}, \mathrm{C}_{6} \mathrm{D}_{6}$ ): $\delta 6.97(2 \mathrm{H}, \mathrm{dd}, J=7.5,1.8 \mathrm{~Hz}), 6.92(2 \mathrm{H}$, dd, $J=7.3,1.8 \mathrm{~Hz}), 6.83(2 \mathrm{H}, \mathrm{dd}, J=7.5,1.8 \mathrm{~Hz}), 6.72(2 \mathrm{H}, \mathrm{t}, J=7.5 \mathrm{~Hz}), 6.70(2 \mathrm{H}, \mathrm{dd}$, $J=7.3,1.8 \mathrm{~Hz}), 6.56(2 \mathrm{H}, \mathrm{t}, J=7.3 \mathrm{~Hz}), 4.87(2 \mathrm{H}, \mathrm{br}$, central thf- $\alpha), 4.50(2 \mathrm{H}, \mathrm{br}$, central thf $-\alpha$ ), $2.86(2 \mathrm{H}, \mathrm{m}$, propyl $-\alpha-\mathrm{CH}), 2.79(2 \mathrm{H}, \mathrm{m}$, propyl $-\alpha-\mathrm{CH}), 2.69(4 \mathrm{H}, \mathrm{br}$, terminal thf $-\alpha$ ), $2.48(2 \mathrm{H}, \mathrm{m}$, propyl $-\alpha-\mathrm{CH}), 2.43(2 \mathrm{H}, \mathrm{m}$, propyl $-\alpha-\mathrm{CH}), 2.24(2 \mathrm{H}, \mathrm{br}$, central thf $-\beta$ ), $1.83(2 \mathrm{H}, \mathrm{br}$, central thf $-\beta), 1.73 \sim 1.68(8 \mathrm{H}, \mathrm{m}$, propyl- $\beta-\mathrm{CH}$ 's, overlapping), $1.51(3 \mathrm{H}, \mathrm{t}, J=8 \mathrm{~Hz}), 0.99(6 \mathrm{H}, \mathrm{t}, J=7.5 \mathrm{~Hz}), 0.97(6 \mathrm{H}, \mathrm{t}, J=7.5 \mathrm{~Hz})$, $0.64(4 \mathrm{H}, \mathrm{br}$, terminal thf $-\beta), 0.62(3 \mathrm{H}, \mathrm{t}, J=8 \mathrm{~Hz}), 0.30(3 \mathrm{H}, \mathrm{q}, J=8 \mathrm{~Hz}),-0.62(3 \mathrm{H}, \mathrm{q}$, $J=8 \mathrm{~Hz}$ ). ${ }^{13} \mathrm{C}$ NMR ( $\left.125 \mathrm{MHz}, \mathrm{APT}, \mathrm{C}_{6} \mathrm{D}_{6}\right): \delta 156.0\left(4^{\circ}\right), 153.3\left(4^{\circ}\right), 150.2\left(4^{\circ}\right), 147.0$ $\left(4^{\circ}\right), 133.6\left(4^{\circ}\right), 132.7\left(4^{\circ}\right), 131.9\left(4^{\circ}\right), 131.7\left(4^{\circ}\right), 129.5\left(3^{\circ}\right), 129.1\left(3^{\circ}\right), 127.9\left(3^{\circ}\right), 126.8$ $\left(3^{\circ}\right), 121.2\left(3^{\circ}\right), 118.5\left(3^{\circ}\right), 71.4$ (thf), 70.3 (thf), 33.5, 33.4, 25.9 (thf), 24.5 (thf), 23.4, 23.1, 14.3, 14.2, 9.8, 8.7, $0.05,-1.8$. To a suspension of 25 ( $\mathrm{FW}=968.7$ based on the elemental analysis, $0.4536 \mathrm{~g}, 0.4683$ mmol ) in 7 mL of toluene was added $\mathrm{Et}_{2} \mathrm{AlCl}(0.2295 \mathrm{~g}, 1.903 \mathrm{mmol})$ dissolved in 2 mL of toluene. The mixture became clear within a few minutes, then turned cloudy again upon longer stirring. After 16 h the volatiles were removed from the mixture, the residue was triturated with toluene, filtered, and the filtrate was concentrated. By adding some hexanes to the concentrate and cooling to $-30^{\circ} \mathrm{C}$, analytically pure crystals were obtained $(0.1611 \mathrm{~g}, 41.6 \%)$. Repeating the crystallization yielded an additional $0.087 \mathrm{~g}(23 \%)$. ${ }^{1} \mathrm{H}$ NMR ( $400 \mathrm{MHz}, \mathrm{C}_{6} \mathrm{D}_{6}$ ): $\delta 6.89(4 \mathrm{H}, \mathrm{dd}, J=7.5,1.8 \mathrm{~Hz}), 6.77(4 \mathrm{H}, \mathrm{dd}, J=7.5,1.8$ $\mathrm{Hz}), 6.70(4 \mathrm{H}, \mathrm{t}, J=7.5 \mathrm{~Hz}), 4.40\left(4 \mathrm{H}, \mathrm{m}\right.$, thf), $2.77\left(4 \mathrm{H}, \mathrm{m}\right.$, propyl- $\left.\alpha-\mathrm{CH}_{2}\right), 2.41(4 \mathrm{H}, \mathrm{m}$, propyl- $\left.\alpha-\mathrm{CH}_{\mathrm{b}}\right), 1.70\left(4 \mathrm{H}, \mathrm{m}\right.$, thf), $1.63\left(8 \mathrm{H}, \mathrm{m}\right.$, propyl $\left.-\beta-\mathrm{CH}_{2} \mathrm{H}_{\mathrm{b}}\right), 1.44(6 \mathrm{H}, \mathrm{t}, J=8.2 \mathrm{~Hz})$, $0.98\left(12 \mathrm{H}, \mathrm{t}, J=7.3 \mathrm{~Hz}\right.$, propyl- $\left.\gamma-\mathrm{CH}_{3}\right), 0.56(6 \mathrm{H}, \mathrm{t}, J=8.2 \mathrm{~Hz}), 0.18(4 \mathrm{H}, \mathrm{q}, J=8.2 \mathrm{~Hz})$, $0.80(4 \mathrm{H}, \mathrm{q}, J=8.2 \mathrm{~Hz}) .{ }^{13} \mathrm{C}$ NMR ( 100 MHz, APT, $\mathrm{C}_{6} \mathrm{D}_{6}$ ): $\delta 152.6$ ( $4^{\circ}$ ), 149.0 (C=C), $133.2\left(4^{\circ}\right), 131.8\left(4^{\circ}\right), 129.4\left(3^{\circ}\right), 127.6\left(3^{\circ}\right), 121.3\left(3^{\circ}\right), 70.5$ (thf), 31.2, 25.6 (thf), 23.1, 14.2, 9.8, 8.6, 0.24, -1.9. Chapter 3 3.4. Experimental page 163

NMR-tuive reaction 1. In ca. 0.5 mL of $\mathrm{C}_{6} \mathrm{D}_{6}, 25$ ( $\mathrm{FW}=998,0.0063 \mathrm{~g}, 0.0063 \mathrm{mmol}$ ) and $\mathrm{EtAlCl}_{2}(0.0009 \mathrm{~g}, 0.007 \mathrm{mmol})$ were mixed. The starting material was not well dissolved initially, but became mostly dissolved during 1.3 h of occasional shaking. After overnight, the solution showed three compounds: 25,43 and 44 in a $1.4: 4.7: 1$ ratio by 'H NMR spectroscopy.
NMR-tube reaction 2. In ca. 0.5 mL of $\mathrm{C}_{6} \mathrm{D}_{6}, 25(\mathrm{FW}=920,0.0057 \mathrm{~g}, 0.0062 \mathrm{mmol})$ and $\mathrm{EtAlCl}_{2}(0.0024 \mathrm{~g}, 0.019 \mathrm{mmol})$ were mixed. The reaction was complete within 4 h as determined by ${ }^{1} \mathrm{H}$ NMR spectroscopy. The mixture showed a $2: 1$ ratio of $43: 44$. After an additional portion of $\mathrm{EtAlCl}_{2}(0.0020 \mathrm{~g}, 0.016 \mathrm{mmol})$ was added, the product became 44 exclusively within 45 min (accompanied by some minor unknown species).
43. ## 45: $\left\{\mathrm{C}_{38} \mathrm{H}_{40} \mathrm{O}_{4}\left[\mathrm{Ti}\left(\mathrm{CH}_{2} \mathrm{C}_{6} \mathrm{H}_{5}\right)\right][\mathbf{M g}(\mathrm{Cl})(\mathrm{thf})]\right\}_{2}$

25

45

The in situ formation of $\mathrm{Bn}_{3} \mathrm{TiCl}$ used in this procedure was based on the report by Ivanova et al. ${ }^{11}$ In the drybox, a solution of $\mathrm{TiBn}_{4}(0.0214 \mathrm{~g}, 0.0519 \mathrm{mmol})$ in toluene ( 5 mL ) and a solution of $\mathbf{2 5}$ in toluene ( 3 mL ) were prepared in separate reaction bombs. A solution of $\mathrm{TiCl}_{4}$ in toluene was measured in a polyethylene syringe $(2.08 \mathrm{mmol} / \mathrm{mL}, 1.0$ $\mathrm{mL}, 2.08 \mathrm{mmol}$ ) with the needle tip stuck into a rubber stopper to protect the contents
from air. All solutions were taken out of the drybox, kept under $\mathbf{N}_{\mathbf{2}}$ atmosphere using the Schlenk line. The $\mathrm{TiBn}_{4}$ solution was cooled to $-50^{\circ} \mathrm{C}$, and the solution of $\mathrm{TiCl}_{4}$ was injected into it. After 18 min . of stirring, the solution of $\mathbf{2 5}$ was transferred by cannula into the mixture. The temperature was raised very slowly and the mixture was stirred overnight. The final color was brown, lighter than in the beginning, and slightly cloudy. The volatiles were removed in vacuo, the bomb brought into the drybox, and the residue was triturated with toluene. After filtration through Celite-packed pipette, the filtrate was concentrated and recrystallized by adding a few drops of hexane and cooling to $-30^{\circ} \mathrm{C}$. After removing the mother liquor, washing the crystals with pentane, and drying under reduced pressure, analytically pure crystalline product was obtained ( $0.0193 \mathrm{~g}, 45 \%$ ). The mother liquor still contains considerable amount of the product, according to the ${ }^{\mathbf{}} \mathrm{H}$
 br t, $J=7.7 \mathrm{~Hz}), 6.94(1 \mathrm{H}, \mathrm{br} \mathrm{t}, J=7.3 \mathrm{~Hz}), 6.85(2 \mathrm{H}+2 \mathrm{H}$, overlapping), $6.72(2 \mathrm{H}, \mathrm{dd}, J$ $=7.5,1.7 \mathrm{~Hz}), 6.63(2 \mathrm{H}, \mathrm{dd}, J=7.5,1.7 \mathrm{~Hz}), 6.58(2 \mathrm{H}, \mathrm{t}, J=7.4 \mathrm{~Hz}), 6.50(2 \mathrm{H}, \mathrm{t}, J=7.5$ Hz ), 3.86 ( $2 \mathrm{H}, \mathrm{br}, \alpha-\mathrm{CH}_{\mathrm{a}}$ ), $3.62\left(2 \mathrm{H}, \mathrm{s}, \mathrm{PhCH}_{2}\right), 3.05(4 \mathrm{H}, \mathrm{br}, \mathrm{thf}), 2.71\left(2 \mathrm{H}, \mathrm{m}, \alpha-\mathrm{CH}_{2}\right)$, 2.47 ( $2 \mathrm{H}, \mathrm{m}, \beta-\mathrm{CH}_{2}$ ), 2.26 ( $2 \mathrm{H}, \mathrm{m}, \beta-\mathrm{CH}_{\mathrm{b}}$ ), 2.17 ( $2 \mathrm{H}, \mathrm{br}-\mathrm{m}, \alpha-\mathrm{CH}_{\mathrm{b}}$ ), $1.84\left(2 \mathrm{H}, \mathrm{b}, \alpha-\mathrm{C}^{2} \mathrm{H}_{\mathrm{b}}\right.$ ), $1.45\left(4 \mathrm{H}, \mathrm{m}, \beta-\mathrm{C}_{\mathrm{a}} \mathrm{H}_{\mathrm{b}}\right), 1.27(6 \mathrm{H}, \mathrm{t}, J=7.3 \mathrm{~Hz}), 0.88(6 \mathrm{H}, \mathrm{t}, J=7.3 \mathrm{~Hz}), 0.77(4 \mathrm{H}, \mathrm{br}$, thf). ${ }^{13} \mathrm{C}$ NMR ( $125 \mathrm{MHz}, \mathrm{BB}, \mathrm{C}_{6} \mathrm{D}_{6}$ ): $\boldsymbol{\delta} 161.0,160.0,158.3,148.1,146.0,133.6,132.7$, 132.0, 129.7, 128.7, 128.5, 128.1, 127.5, 127.2, 124.3, 123.8, 121.2, 120.5, $88.6\left(\mathrm{PhCH}_{2}\right)$, 70.0 (thf), 34.2, 32.4, 24.6 (thf), 23.5, 23.0, 14.8, 14.3. Found: C, 69.90; H , 6.48. X-ray crystallography: see Appendix A-15.

The scale-up of this reaction was not successful. The major problem was probably external, the degradation of $\mathrm{TiCl}_{4}$ due to the use of a Schlenk flask instead of a reaction bomb. It is often observed that maintaining $\mathrm{TiCl}_{4}$ neat or in toluene in a Schlenk flask under nitrogen causes a yellow precipitate to separate out of the liquid/solution. The rubber septum (or the plasticizer in the septum) is suspected to cause this problem, even without direct contact. It is also suspected that normal pre-purified nitrogen is not innocent either, as long as it comes through a rubber tube connecting the Schlenk line to the flask. Although the period of exposure was minimized to $<15$ minutes to avoid this situation, some precipitate formation was still observed. The failed scale-up run resulted in a mixture of the titanium-sandwich complex 32 (Section 3.1.2.D) and unidentified species that showed broad signals in the ${ }^{1} \mathrm{H}$ NMR spectrum. The formation of $\mathbf{3 2}$ suggests that the reaction between $\mathrm{TiCl}_{4}$ and $\mathrm{TiBn}_{4}$ was possibly incomplete. No further scale-up was attempted.

\frac{2 \text { equiv. } \mathrm{TiCl}_{4}}{\text { toluene }}
$$

46/46'

To a suspension of $42(0.0569 \mathrm{~g}, 0.0688 \mathrm{mmol})$ in 0.5 mL of toluene was added $\mathrm{TiCl}_{4}$ ( $0.0261 \mathrm{~g}, 0.138 \mathrm{mmol}$ ) dissolved in 1 mL of toluene. The mixture became dark red immediately. After 2 h , the volatiles were removed from the mixture and the residue was triturated with pentane, filtered, and the filtrate was concentrated. The crude yield was 0.0474 g (\% yield is not calculated because the molecular weight of the product was uncertain). Repeated crystallization from pentane (r.t. $\rightarrow-30^{\circ} \mathrm{C}$ ) yielded ruby-red crystals that was analyzed by X-ray crystallography. After removing some crystals for elemental analysis, the rest of the crystals along with dried remnant from mother liquor, was analyzed by ${ }^{\prime} \mathrm{H}$ and ${ }^{13} \mathrm{C}$ NMR spectroscopy. The spectrum showed 46 and 40 ' in a 1 : 1 ratio as major species, accompanied by other minor species.
${ }^{1} \mathrm{H}$ NMR ( $360 \mathrm{MHz}, \mathrm{C}_{6} \mathrm{D}_{6}$ ): the signals are tentatively assigned to either $\mathbf{4 6}$ or 46 ' or unclassifiable, based on the comparison to the results from other reactions (Section 3.2.3, Scheme 3.18) containing different ratios of these species. Signals from the liberated aluminum species are not listed.
46. ${ }^{1} \mathrm{H}$ NMR ( $360 \mathrm{MHz}, \mathrm{C}_{6} \mathrm{D}_{6}$ ): $\delta 6.80(2 \mathrm{H}, \mathrm{dd}, J=7.7 \mathrm{~Hz}$ ), 6.76 ( 2 H , dd, $J=\sim 8,1 \sim 1.5$ Hz ), the other $2 \mathrm{H} \times 4$ signals are in the regions $6.79 \sim 6.75$ or $6.65 \sim 6.55 \mathrm{ppm}$, but not clearly identified; $2.84(2 \mathrm{H}, \mathrm{m}$, propyl- $\alpha-\mathrm{CH}$ ), $2.65(2 \mathrm{H}, \mathrm{m}$, propyl $-\alpha-\mathrm{CH}), 2.49(2 \mathrm{H}, \mathrm{m}$, propyl- $\alpha-\mathrm{CH}$ ), $2.37(2 \mathrm{H}, \mathrm{m}$, propyl- $\alpha-\mathrm{CH}$ ), $1.74(2 \mathrm{H}, \mathrm{m}$, propyl $-\beta-\mathrm{CH}), 1.64(2 \mathrm{H}, \mathrm{m}$ ?, propyl- $\beta-\mathrm{CH}$ ?), $1.44\left(4 \mathrm{H}, \mathrm{m}\right.$, propyl- $\left.\beta-\mathrm{CH}_{2}\right), 0.98\left(6 \mathrm{H}, \mathrm{t}, \mathrm{J}=7.3 \mathrm{~Hz}\right.$, propyl- $\left.\gamma-\mathrm{CH}_{3}\right), 0.77$ $\left(6 \mathrm{H}, \mathrm{t}, J=7.3 \sim 7.5 \mathrm{~Hz}\right.$, propyl $\left.-\gamma-\mathrm{CH}_{3}\right), 0.585\left(3 \mathrm{H}, \mathrm{t}, J=8 \mathrm{~Hz}, \mathrm{AlCH}_{2} \mathrm{CH}_{2}\right),-0.65(2 \mathrm{H}, \mathrm{q}, J$ $=8 \mathrm{~Hz}, \mathrm{AlCH}_{2} \mathrm{CH}_{3}$ ). 46': ${ }^{1} \mathrm{H}$ NMR ( $360 \mathrm{MHz}, \mathrm{C}_{6} \mathrm{D}_{6}$ ): $\delta 6.79 \sim 6.75 \mathrm{ppm}$ and $6.65 \sim 6.55$ ppm ( $2 \mathrm{H} \times 6$, overlapping themselves and with signals from 46 ), $3.00(2 \mathrm{H}, \mathrm{m}$, propyl- $\alpha$ CH ), $2.98(2 \mathrm{H}, \mathrm{m}$, propyl $-\alpha-\mathrm{CH}), 2.55(4 \mathrm{H}$, overlapping m , propyl $-\alpha-\mathrm{CH}$ ), $2.35(2 \mathrm{H}, \mathrm{m}$, propyl- $\alpha-\mathrm{CH}$ ), $2.88 \sim 1.55(8 \mathrm{H}$, overlapping m , propyl $-\beta-\mathrm{CH}), 1.04(6 \mathrm{H}, \mathrm{t}, J=7.3 \mathrm{~Hz}$, propyl $\left.-\gamma-\mathrm{CH}_{3}\right), 0.86\left(6 \mathrm{H}, \mathrm{t}, J=7.3 \mathrm{~Hz}\right.$, propyl $\left.-\gamma-\mathrm{CH}_{3}\right), 0.605(3 \mathrm{H}, \mathrm{t}, J=8 \mathrm{~Hz}$, $\left.\mathrm{AlCH}_{2} \mathrm{CH}_{3}\right), \mathbf{0 . 3 8}\left(2 \mathrm{H}, \mathrm{q}, \mathrm{J}=8 \mathrm{~Hz}, \mathrm{AlCH}_{2} \mathrm{CH}_{3}\right)$. ### 4.0. Introduction

The coordination chemistry of the di-hydroxy-di-methoxy ligands 3 E and $3 \mathrm{Z}, E$ and Z-bis(2-benzyloxyphenyl)-bis(2-methoxyphenyl)ethene, was studied using Al(III), $\mathrm{Ti}(\mathrm{IV})$ and Mg (II) metal atoms, following the general direction of our research (Chapter 2). The synthesis, structural and spectroscopic features, and chemical behavior of metal complexes prepared from ligands 3 E and 3 Z are presented in this chapter.

Many discrete Al (III) and $\mathrm{Ti}(\mathrm{IV})$ complexes were obtained for the $E$-ligand $\mathbf{3 E}$, including hetero-polymetallic $\mathrm{Al} / \mathrm{Ti}$ species. The preliminary titanium chemistry of Z ligand 3Z, however, showed that this ligand is less suitable for creating discrete complexes. Only one Ti complex was structurally characterized for ligand 3Z. Neither 3E nor $3 Z$ gave discrete $\mathbf{M g}$ salts, in contrast to the ortho-propylated tetrahydroxy ligand 7, which provided well-defined tri-nuclear magnesium complexes and derivatives (Chapter 3).

In this chapter, mono- and dinuclear aluminum complexes derived from $\mathbf{3 E}$ and their chemical interconversions are discussed first. Coordinating solvents induced aluminum-abstraction chemistry to convert dinuclear complexes into mononuclear species. A similar chemistry was discussed for the aluminum complexes of ligand 7 (Chapter 3, Section 3.1.3). The aluminum chemistry of ligand 3E also showed the reverse of the aluminum abstraction when a second aluminum center was added to a mononuclear complex to form dinuclear species.

The titanium chemistry of ligands $\mathbf{3 E}$ and $3 Z$ is presented in the next section. Several mononuclear titanium complexes of 3 E were synthesized and structurally characterized. The Z-ligand 3Z, in contrast, exhibited poor chelating and organizing behavior in the formation of discrete complexes.

Our attempts to construct hetero-polymetallic species on the $\mathbf{3 E}$ system are described in the final section. Hetero-polymetallic targets were restricted to the combination of Al and Ti metal atoms. One $\mathrm{Al} / \mathrm{Ti}$ hetero-polymetallic complex was cleanly obtained and structurally characterized.

Figure 4.1 provides the list of compounds derived from ligand 3 E and discussed in Chapter 3. Those characterized by X-ray crystallography are indicated in the figure.

### 4.1. Al Complexes of Ligand 3E

Mononuclear and dinuclear aluminum complexes were prepared from ligand 3E and $\mathrm{Et}_{3} \mathrm{Al}$ or $\mathrm{Et}_{2} \mathrm{AlCl}$ with appropriate stoichiometry. The interconversions of the dinuclear and mononuclear aluminum complexes were investigated.

### 4.1.A. Adducts of $\mathrm{Et}_{3} \mathrm{Al}$

The addition of one or two equivalents of $\mathrm{Et}_{3} \mathrm{Al}$ to ligand 3 E in toluene resulted in the formation of the mononuclear ethylaluminum complex 47 and the dinuclear adduct 48 (Scheme 4.1). The structure of $\mathbf{4 8}$ is tentatively assigned (vide infra).

47

Scheme 4.1. Formation of 47 and 48 from the reaction between ligand $3 E$ and one or two equivalents of $\mathrm{Et}_{3} \mathrm{Al}$.
i) Mononuclear "AIEt" complex 47. The reaction that gave complex 47 was clean, and analytically pure crystals were obtained by simple crystallization from benzene. The structure of complex 47 was confirmed by X-ray crystallography (Figure 4.2).

Figure 4.2. X-ray crystallographic structure of 47.
Bond length $(\AA): \mathrm{Cl}-\mathrm{C} 2=1.345(3), \mathrm{Al}-\mathrm{Ol}=1.7883(13), \mathrm{Al}-\mathrm{O} 2=2.0956(14), \mathrm{Al}-\mathrm{O} 3$ $=1.7912(14), \mathrm{Al}-\mathrm{O} 4=2.0862(13), \mathrm{Al}-\mathrm{C} 3=1.9671(17)$. Interatomic angle (deg): $\mathrm{Ol}-$ $\mathrm{Al}-\mathrm{O} 2=87.60(6), \mathrm{Ol}-\mathrm{Al}-\mathrm{O} 3=148.47(6), \mathrm{Ol}-\mathrm{Al}-\mathrm{O} 4=85.01(5), \mathrm{Ol}-\mathrm{Al}-\mathrm{C} 3=$ $105.33(7), \mathrm{O} 2-\mathrm{Al}-\mathrm{O} 3=85.59(6), \mathrm{O} 2-\mathrm{Al}-\mathrm{O} 4=155.66(5), \mathrm{O} 2-\mathrm{Al}-\mathrm{C} 3=102.66(7)$, $\mathrm{O} 3-$ $\mathrm{Al}-\mathrm{O} 4=88.67(6), \mathrm{O} 3-\mathrm{Al}-\mathrm{C} 3=106.20(8), \mathrm{O} 4-\mathrm{Al}-\mathrm{C} 3=101.66(7)$. Torsional angle through $\mathrm{Cl}-\mathrm{C} 2$ bond (deg): $\mathrm{Cl1}-\mathrm{Cl}-\mathrm{C} 2-\mathrm{C} 31=172.56(15), \mathrm{C} 11-\mathrm{Cl}-\mathrm{C} 2-\mathrm{C} 41=$ $-1.4(3), \mathrm{C} 21-\mathrm{Cl}-\mathrm{C} 2-\mathrm{C} 31=-1.9(3), \mathrm{C} 21-\mathrm{Cl}-\mathrm{C} 2-\mathrm{C} 41=-175.89(15)$. Ring torsion angle against $\mathrm{C} 1-\mathrm{C} 2$ bond (deg): $\mathrm{C} 2-\mathrm{C1}-\mathrm{C11}-\mathrm{C1} 2=-65.6(2)$, $\mathrm{C} 2-\mathrm{C1}-\mathrm{Cl1}-\mathrm{Cl} 6=$ 112.8(2), $\mathrm{C} 2-\mathrm{C} 1-\mathrm{C} 21-\mathrm{C} 22=105.4(2), \mathrm{C} 2-\mathrm{C1}-\mathrm{C} 21-\mathrm{C} 26=-74.8(3), \mathrm{C} 1-\mathrm{C} 2-\mathrm{C} 31-\mathrm{C} 32$ $=-66.3(2), \mathrm{Cl}-\mathrm{C} 2-\mathrm{C} 31-\mathrm{C} 36=116.8(2), \mathrm{C} 1-\mathrm{C} 2-\mathrm{C} 41-\mathrm{C} 42=104.9(2), \mathrm{Cl}-\mathrm{C} 2-\mathrm{C} 41-$ C46 $=-75.2(3)$.

In the crystal structure, both of the methoxy groups are coordinated to the Al atom to form pseudo-square pyramidal geometry. The $\mathrm{O}_{4}$ plane is obviously not square, but diamond-shaped with two long and two short Al-O bonds. The Al atom is located above the $\mathrm{O}_{4}$ plane, with no indication of interaction with the olefin double bond. The four aryl rings are tilted in a helical way. The rings with phenolato oxygen donors ( $\mathrm{Cl} 1 \sim \mathrm{Cl}$ and C31~C36 rings) are tilted by ca. $25^{\circ}$ from the position perpendicular to the olefin ring. The other two rings with the methoxy groups are tilted by ca. $15^{\circ}$.

Chapter 4 4.1. Al Complexes page 173

The ${ }^{1} \mathrm{H}$ NMR spectroscopic features are all consistent with the crystallographic structure: all-sharp signals reflecting the rigid structure; symmetrical ligand framework; and slightly split (by $\sim \mathbf{2 H z}$ ) methylene proton signals of the ethyl group reflecting the diastereotopicity. The methoxy signal appears at 3.18 ppm , close to the methoxy signal in the starting material 3E ( 3.21 ppm ).

The ethyl group on the Al atom $\left(\mathrm{CH}_{3}: 1.68 \mathrm{ppm}\right.$ and $\left.\mathrm{CH}_{2}: 0.60 \mathrm{ppm}\right)$ is more downfield than is typical, roughly by 0.3 to $0.7 \mathrm{ppm} .^{.}$The position right above the central metal atom was found to be deshielded in the trinuclear magnesium complexes 25 to 29, as discussed in Chapter 3, Section 3.1.1 (Figure 4.3): the deshielding for the THF molecule at the central Mg atom was by over 1.4 ppm . The deshielding for the ethyl group in 47 is much weaker: the greater distance from the aryl rings (the central Al atom in 47 is more "above" than the Mg atom in 25) may be partly responsible. The tilting of the aryl rings may also orient the most effective deshielding region away from the ethyl group.

47

25

Figure 4.3. The position above the central metal atom: in 47 and 25.
ii) Dinuclear complex 48. An unsymmetrical dinuclear structure is tentatively assigned to 48, based on the analogy to the related dinuclear complex 50 (vide infra). The analytically pure product was obtained by rather quick crystallization/precipitation: adding hexane to a concentrated and already partly cloudy toluene solution, then cooling to $-30{ }^{\circ} \mathrm{C}$. The white, opaque but not crystalline precipitate showed the $\mathrm{C} / \mathrm{H}$ elemental analysis perfectly matching the expected values for a dinuclear product $\mathrm{C}_{28} \mathrm{H}_{22} \mathrm{O}_{4} \mathrm{Al}_{2} \mathrm{Et}_{4}$ $\left(\mathrm{C}_{28} \mathrm{H}_{22} \mathrm{O}_{4}=[3 \mathrm{E}-2 \mathrm{H}]\right)$.

[^12]Chapter 4 4.1. Al Complexes page 174
${ }^{1} \mathrm{H}$ NMR spectroscopy was not helpful in determining the structure of 48 . The ${ }^{1} \mathrm{H}$ NMR spectrum in $\mathrm{C}_{6} \mathrm{D}_{6}$ consists of broad and complicated signals at room temperature, although the integrals of the aromatic region, methoxy and ethylaluminum regions are consistent with the expected formula of 48. At $75^{\circ} \mathrm{C}$, the signals became sharp and simplified, showing a symmetrical, or completely averaged ligand framework.

Interestingly, slow crystallization of 48 yielded crystals of the aforementioned mononuclear complex 47 . When the analytically pure compound 48 was dissolved in toluene and recrystallized by layering on hexanes for slow diffusion, with simultaneous cooling to $-30^{\circ} \mathrm{C}$, a few big, clear prism crystals were formed in the hexanes layer overnight. The crystals turned out to be the mononuclear "AIEt" complex 47, confirmed by ${ }^{1} \mathrm{H}$ NMR spectroscopy and X-ray crystallography (the ORTEP provided in Figure 4.2 was actually from these crystals). The residue after removal of the volatiles from the mother liquid showed a broad and complicated ${ }^{\prime} \mathrm{H}$ NMR spectrum, but the pattern does not match that of 48.

The broadness of the ${ }^{1} H$ NMR signals of 48 and the formation of the mononuclear crystal 47 from the solution suggest that the dinuclear species 48 exists in equilibrium with 47 in solution (Scheme 4.2).

Scheme 4.2. Equilibrium between 48 and 47.

The equilibrium was confirmed by a reaction between 47 and one equivalent of $\mathrm{Et}_{3} \mathrm{Al}$ in $\mathrm{C}_{6} \mathrm{D}_{6}$ to produce 48 . The resulting mixture showed broad ${ }^{1} \mathrm{H}$ NMR signals very similar to those of $\mathbf{4 8}$. The mother liquor of the crystallization of $\mathbf{4 7}$ from a solution of $\mathbf{4 8}$ must have contained a higher stoichiometry of $\mathrm{Et}_{3} \mathrm{Al}$, affecting the equilibrating system and producing a different appearance.

### 4.1.B. Adducts of $E t_{2} A I C I$

The results from the addition of one or two equivalents of $\mathrm{Et}_{2} \mathrm{AlCl}$ to ligand $\mathbf{3 E}$ were mostly analogous to the addition of $\mathrm{Et}_{3} \mathrm{Al}$ described in the previous section. The one-equivalent addition resulted in a mononuclear " AlCl " complex 49, and the twoequivalent addition produced the dinuclear complex 50 (Scheme 4.3). The unsymmetrical structure of 50, confirmed by X-ray crystallography, provided useful information about the chemical behavior of the two-equivalent aluminum adducts 48 and 50.

49
('H NMR, MS)
$\xrightarrow[\text { toluene }]{2 \text { equiv. } \mathrm{Et}_{2} \mathrm{AlCl}}$ toluene

Scheme 4.3. Formation of 49 and 50 from the reaction between ligand $\mathbf{3 E}$ and one or two equivalents of $\mathrm{Et}_{2} \mathrm{AlCl}$.
i) Mononuclear adduct 49. The addition of one equivalent of $\mathrm{Et}_{2} \mathrm{AlCl}$ to 3 E in toluene resulted in the formation of a white precipitate. The high-resolution mass spectrometry of the precipitate showed a parent peak of $\mathrm{C}_{28} \mathrm{H}_{22} \mathrm{O}_{4} \mathrm{AICl}(100 \%)$. The ${ }^{1} \mathrm{H}$ NMR spectroscopy of a dilute solution in $\mathrm{CD}_{3} \mathrm{CN}$ cleanly showed a symmetrical ligand framework with no ethyl group. Both data are consistent with the proposed structure of 49 (Scheme 4.3). A concentrated solution of the precipitate in $\mathrm{CD}_{3} \mathrm{CN}$, however, showed a mixture of 49 and

Chapter 4 4.1. Al Complexes page 176
another unidentified species $(\mathbf{X}$ ) in about a $1: 1$ ratio. In the spectrum, compound $X$ showed the symmetrical ligand framework and relatively broad methoxy groups, a result suggesting a non-rigid structure. Why compound $X$ was not observed in the initial spectrum of the dilute solution is not clear.

Compound X was also found in the reaction of 3 E with two equivalents of $\mathrm{EtAlCl}_{2}$. This recipe was expected to give a dinuclear " $\mathrm{Al}_{2} \mathrm{Cl}_{4}$ " complex. The crude product, however, was a mixture of 49 and $X$ in a $\sim 1: 2$ ratio, according to ${ }^{\prime} H$ NMR spectroscopy in $\mathrm{CD}_{3} \mathrm{CN}$. Thus, compound X might have been the expected dinuclear " $\mathrm{Al}_{2} \mathrm{Cl}_{4}$ " complex. However, this hypothesis was not supported by the observation of $\mathbf{X}$ in the above-mentioned [ $\left.3 \mathrm{E}+1 \mathrm{Et}_{2} \mathrm{AlCl}\right]$ experiment (see Scheme 4.3), in which not enough chloride equivalents were provided. The identity of this symmetrical byproduct $\mathbf{X}$ thus remains unclear.
ii) Dinuclear complex 50. Addition of two equivalents of $\mathrm{Et}_{2} \mathrm{AlCl}$ to ligand 3 E gave the formally dinuclear " $(\mathrm{AIEtCl})_{2}$ " complex 50 as a major product, with a small amount of a mononuclear " AlCl " complex 49 as a byproduct ( 2 to $14 \%$ ). The formation of 49 is presumably the result of the $1: 1$ reaction between 3 E and $\mathrm{Et}_{2} \mathrm{AlCl}$. The $\mathrm{C} / \mathrm{H}$ elemental analysis of the crystallized portion of the product mixture showed the values expected for $\mathrm{C}_{28} \mathrm{H}_{22} \mathrm{O}_{4} \bullet \mathrm{Al}_{2} \bullet \mathrm{Et}_{2} \bullet \mathrm{Cl}_{2}\left(\mathrm{C}_{28} \mathrm{H}_{22} \mathrm{O}_{4}=[3 \mathrm{E}-2 \mathrm{H}]\right)$. The unsymmetrical structure of 50 was confirmed by X-ray crystallography (Figure 4.4). The structure may be described as a "core" mononuclear unit, equivalent to the "AlEt" complex 47, attached to one equivalent of $\mathrm{EtAlCl}_{2}$ at the second lone pair of one of the "ArO" groups coordinated to the central aluminum atom. One methoxy ether group remains as a spectator. It is interesting that the $\mathrm{EtAlCl}_{2}$ unit stays intact on the core molecule, with no dissociation.

Unlike the " $\mathrm{Al}_{2} \mathrm{Et}_{4}$ " analogue 48, complex 50 shows sharp ${ }^{\text {' }} \mathrm{H}$ NMR signals (in $\mathrm{C}_{6} \mathrm{D}_{6}$ ) at room temperature. The ${ }^{1} \mathrm{H}$ NMR spectrum is consistent with the unsymmetrical ligand framework shown in the crystal structure, with two inequivalent ethyl groups. The sixteen aromatic signals (from four different aryl rings) are widely spread between 7.73 and 6.11 ppm . The sharpness of the signals supports the conclusion that $\mathrm{EtAlCl}_{2}$ does not dissociate, but is tightly bound to the core. At $75{ }^{\circ} \mathrm{C}$, the signals become slightly broadened, possibly indicating partial dissociation of " $\mathrm{EtAlCl}_{2}$ " unit, but the unsymmetrical structure still being preserved.

Figure 4.4. X-ray crystallographic structure of 50.
Bond lengths $(\AA): \mathrm{Cl} 1-\mathrm{Al} 2=2.156(2), \mathrm{Cl} 2-\mathrm{Al} 2=2.142(3), \mathrm{All}-\mathrm{Ol}=1.852(4), \mathrm{All}-$ $\mathrm{O} 2=1.920(4), \mathrm{All}-\mathrm{O} 3=1.707(4), \mathrm{All}-\mathrm{C} 3=1.934(5), \mathrm{Al2}-\mathrm{Ol}=1.864(4), \mathrm{Al} 2-\mathrm{C} 5=$ 1.942(6), $\mathrm{Cl}-\mathrm{C} 2=1.328(8)$. Interatomic angles (deg): O1-Al1-O2 $=197.40(17)$, $\mathrm{Ol}-$ All-O3 = $1122.0(2), \mathrm{O} 1-\mathrm{All}-\mathrm{C} 3=1112.3(2), \mathrm{O} 2-\mathrm{All}-\mathrm{O} 3=1102.40(19), \mathrm{O} 2-\mathrm{All}-\mathrm{C} 3$ $=1101.1(2), \mathrm{O} 3-\mathrm{All}-\mathrm{C} 3=1116.3(2), \mathrm{Cl1}-\mathrm{Al} 2-\mathrm{Cl} 2=1107.44(10), \mathrm{Cl1}-\mathrm{Al} 2-\mathrm{Ol}=$ 1105.41(14), $\mathrm{Cl} 1-\mathrm{Al} 2-\mathrm{C} 5=1113.2(2), \mathrm{Cl} 2-\mathrm{Al} 2-\mathrm{Ol}=199.15(14), \mathrm{Cl} 2-\mathrm{Al} 2-\mathrm{C} 5=$ 1118.3(2), $\mathrm{Ol}-\mathrm{Al} 2-\mathrm{C} 5=1111.8(2)$. Torsional angles of olefin plane (deg): $\mathrm{Cl} 1-\mathrm{Cl}-$ $\mathrm{C} 2-\mathrm{C} 31=162.8(5), \mathrm{C} 11-\mathrm{C} 1-\mathrm{C} 2-\mathrm{C} 41 \mathrm{~A}=-2.3(11), \mathrm{C} 11-\mathrm{C} 1-\mathrm{C} 2-\mathrm{C} 41 \mathrm{~B}=-32.3(10)$, $\mathrm{C} 21-\mathrm{C} 1-\mathrm{C} 2-\mathrm{C} 31=-14.3(8), \mathrm{C} 21-\mathrm{C} 1-\mathrm{C} 2-\mathrm{C} 41 \mathrm{~A}=-179.4(7), \mathrm{C} 21-\mathrm{Cl}-\mathrm{C} 2-\mathrm{C} 41 \mathrm{~B}=$ 150.6(8). Ring torsion angles (deg): $\mathrm{C} 2-\mathrm{C} 1-\mathrm{Cl1}-\mathrm{Cl} 2=-70.0(7), \mathrm{C} 2-\mathrm{Cl}-\mathrm{Cl} 1-\mathrm{Cl} 6=$ 117.7(7), C2-C1-C21-C22 = 118.2(7), C2-C1-C21-C26 = -59.9(8), C1-C2-C31-C32 $=-61.1(8), \mathrm{C} 1-\mathrm{C} 2-\mathrm{C} 31-\mathrm{C} 36=119.3(7), \mathrm{C} 1-\mathrm{C} 2-\mathrm{C} 41 \mathrm{~A}-\mathrm{C} 42 \mathrm{~A}=-56.3(11), \mathrm{C} 1-\mathrm{C} 2-$ C41A-C46A $=124.3(11), \mathrm{C} 1-\mathrm{C} 2-\mathrm{C} 41 \mathrm{~B}-\mathrm{C} 42 \mathrm{~B}=141.5(13), \mathrm{C} 1-\mathrm{C} 2-\mathrm{C} 41 \mathrm{~B}-\mathrm{C} 46 \mathrm{~B}=$ -25(2).

The methylene protons of both ethyl groups, one on the central Al atom and the other in the terminal $\mathrm{AIEtCl}_{2}$ unit, are notably split, reflecting the highly unsymmetrical structure. The chemical shifts and appearance of these two ethyl groups are quite different: one is sharp and downfield-shifted compared to free $\mathrm{EtAlCl}_{2}$ (by 1.1 to 0.6 ppm), and the other is upfield-shifted (by 0.8 to 1 ppm ) and slightly broad. ${ }^{\text {b }}$ The former is assigned to the ethyl group on the central AI atom, from the similar chemical shift to the ethyl group in the mononuclear complex 47. The latter is therefore the ethyl group in the terminal " $\mathrm{AlEtCl}_{2}$ " unit. Its upfield-shift relative to free $\mathrm{EtAlCl}_{2}$ obviously comes from the additional dative coordination by the oxygen donor of the core complex. The broadness of the terminal ethyl signals comes most likely from the slow rotation around the $\mathrm{O}-\mathrm{AlEtCl}_{2}$ bond.

The formation of the dinuclear ( AIEt ) $\left(\mathrm{AlEtCl}_{2}\right)$ complex 50 may be explained as a stepwise reaction of 3 E with $\mathrm{Et}_{2} \mathrm{AlCl}$, as suggested in Scheme 4.4. In this scheme, the reaction of 3 E with the first equivalent of $\mathrm{Et}_{2} \mathrm{AlCl}$ gives 49, the mononuclear " AlCl " complex. The second equivalent of $\mathrm{Et}_{2} \mathrm{AlCl}$ first interacts at the second lone pair of an aryloxy oxygen, then replaces the chloride in 49 with an ethyl group to give 50 .

Scheme 4.4. Proposed mechanism for the formation of 50.

[^13]Chapter 4 4.1. Al Complexes page 179

The structure of 50 and the apparent intramolecular disproportionation strongly suggests that similar chemistry occurs to the two-equivalent adduct of $\mathrm{Et}_{3} \mathrm{Al}$ (48, see Scheme 4.1). The greatest difference is that the $\mathrm{Et}_{3} \mathrm{Al}$ moiety is not always intact in 48, but partly dissociates in solution (Scheme 4.5). $\mathrm{Et}_{3} \mathrm{Al}$ is less Lewis acidic than $\mathrm{EtAlCl}_{2}$, thus requiring less stabilization by the oxygen donor of the "core" complex 47. The dissociation of $\mathrm{Et}_{3} \mathrm{Al}$ allows the formation of mononuclear complex 47 in solution, which can be crystallized out by a slow crystallization process (Section 4.1.A-ii).

Scheme 4.5. Proposed structure of $\mathbf{4 8}$ and mechanism of the formation.

### 4.1.C. Aluminum Abstraction by Coordinating Solvent

When dissolved in a coordinating solvent, $\mathrm{CD}_{3} \mathrm{CN}$, the dinuclear complexes 48 and 50 both showed a mixture of mononuclear complex 47 and liberated $\mathrm{Et}_{3} \mathrm{Al}$ or EtAICl ${ }_{2}$, respectively, in the ${ }^{\prime} \mathrm{H}$ NMR spectroscopy (Scheme 4.6). $\mathrm{CD}_{3} \mathrm{CN}$ presumably stabilized the liberated $\mathrm{Et}_{3} \mathrm{Al}$ or $\mathrm{EtAlCl}_{2}$ moieties by coordination, preventing the reaction with 47 from going back to the dinuclear species. This behavior further supports the suggestion that the structure of 48 is an unsymmetrical ( AlEt )( $\mathrm{AlEt}_{3}$ ) species (analogous to that of 50 ), in which the $\mathrm{AlEt}_{3}$ unit is "ready" to dissociate.

Scheme 4.6. Aluminum abstraction by $\mathrm{CD}_{3} \mathrm{CN}$ from 48 and 50 .

### 4.1.D. From Mononuclear to Dinuclear

It was shown (Section 4.1.A-ii) that the addition of one equivalent of $\mathrm{Et}_{3} \mathrm{Al}$ to the mononuclear complex 47 in $\mathrm{C}_{6} \mathrm{D}_{6}$ produced the same ${ }^{1} \mathrm{H}$ NMR spectrum as that of the dinuclear complex 48 (Scheme 4.7 -a). This "reverse" formation of a dinuclear system from the core mononuclear complex was also successful in converting 47 into 50 (Scheme 4.7-b). The same approach but using $\mathrm{Et}_{2} \mathrm{AlCl}$ was used to produce a new dinuclear complex 51, which cannot be produced from the addition of two equivalents of an alkylaluminum reagent to ligand 3E (Scheme 4.7-c). The structure of 51 depicted in Scheme 4.7-c is tentatively assigned based on the unsymmetrical ligand framework observed in the 'H NMR spectrum, the appearance of three different ethyl groups, and by analogy to the other cases shown in the scheme.

The 'H NMR signals of 51 are all slightly broadened, suggesting some degree of dissociation of the " $\mathrm{AlEt}_{2} \mathrm{Cl}$ " unit in solution. The unsymmetrical framework, however, is kept reasonably intact. The degree of dissociation is obviously intermediate between complexes 48 and 50 , reflecting the intermediate Lewis acidity of the corresponding alkyl moiety $\mathrm{Et}_{2} \mathrm{AlCl}$.

(a)
(b)

(c)

Scheme 4.7. Addition of alkylaluminum reagent to 47.

### 4.2. Ti Complexes of Ligands 3E/3Z

The chemical behavior of ligands 3 E and 3 Z toward titanium reagents was quite different. The former showed its capability/preference to form chelating mononuclear complexes, such as " $\mathrm{TiCl}_{2}$ " complex 52, "CpTiCl" complex 54, and " $\mathrm{TiBn}_{2}$ " complex 55 (vide infra). The latter, in contrast, showed no preference for chelation or formation of discrete complexes.

### 4.2.A. $\mathrm{TICl}_{2}$ Complex of 3E

The mononuclear " $\mathrm{TiCl}_{2}$ " complex 52 was synthesized by adding one equivalent of $\mathrm{TiCl}_{4}$ to 3 E in toluene medium, with or without prior deprotonation by two equivalents of NaH (Scheme 4.8). The use of more than one equivalent of $\mathrm{TiCl}_{4}$ still resulted in the formation of 52, although use of a large excess (six equivalents) of the reagent increased byproduct formation. The formation of the chelated mononuclear complex in the presence of excess $\mathrm{TiCl}_{4}$ suggests that the ligand has a strong tendency to chelate one metal rather than to form dinuclear species or intermolecularly bridged aggregates.

Scheme 4.8. Preparation of complex 52.

The solid state structure of $\mathbf{5 2}$ was confirmed by X-ray crystallography (Figure 4.5). The Ti atom takes a pseudo-trigonal bipyramidal coordination geometry, having the two ArO groups and one chloride at the equatorial positions, and one methoxy group and the other chloride at the axial positions. The other methoxy group is not coordinated to the Ti atom, but is turned away from the coordination face, making a "three-up/one down" conformation of the ligand framework. The aryl rings are tilted from the position perpendicular to the olefin plane by approximately 25 to $28^{\circ}$, except for one ring that is off by only $-16^{\circ}$. This least-tilting ring is one of the rings with an anionic oxygen donor. The direction of the ring tilting is helical, like the other crystallographically characterized complexes 47 and 50.

Although the solid state structure of $\mathbf{5 2}$ revealed that the two methoxy groups are inequivalent, the ligand framework appeared symmetrical in solution phase (in $\mathrm{C}_{6} \mathrm{D}_{6}$ ) at room temperature, according to ${ }^{1} \mathrm{H}$ NMR spectroscopy. The single methoxy signal, however, was slightly broadened. The two methoxy groups, one coordinating to the metal center and one not, are presumably exchanging rapidly at room temperature.

Low temperature ${ }^{1} \mathrm{H}$ NMR spectroscopy (toluene $-\mathrm{d}_{8}$ ) showed the "frozen" unsymmetrical structure observed in the crystal state. As the temperature was lowered from $25^{\circ} \mathrm{C}$, the methoxy signal became further broadened, split at between $0^{\circ} \mathrm{C}$ and -20 ${ }^{\circ} \mathrm{C}$, and became sharp again at around $-60^{\circ} \mathrm{C}$. The methoxy signals broaden again below $-80^{\circ} \mathrm{C}$. (No attempt was made to quantify the dissociation energy.)

The reaction that gave complex 52 was reasonably clean, giving a purified yield of $\sim 70 \%$, but was often accompanied by minor byproducts. Mass spectrometry indicates that one byproduct has the formula [ $52-\mathrm{CH}_{3} \mathrm{Cl}$ ], suggesting that de-alkylation of the
coordinated methoxy residue. In an attempt to form this suspected byproduct independently, complex 52 was treated with $\mathrm{Et}_{4} \mathrm{NCl}$ in toluene- $\mathrm{d}_{8}$ at $80{ }^{\circ} \mathrm{C}$. This reaction was not clean, as was indicated by the emergence of at least four new methoxy signals and a very complicated aromatic region in the ${ }^{1} \mathrm{H}$ NMR spectrum. The spectrum, however, showed the emergence of a sharp singlet at 2.34 ppm , which was tentatively attributed to $\mathrm{CH}_{3} \mathrm{Cl}$ but not confirmed. Prolonged heating led to precipitation of a red solid, which gave a formula of $\mathrm{C}_{27} \mathrm{H}_{19} \mathrm{O}, \mathrm{TiCl}$ by high-resolution mass spectrometry, although no further confirmation of structure could be attained. Heating in THF, instead of toluene, may have resulted in a cleaner reaction, as Floriani et al. observed such a transformation with the calix[4]arene analogue.'

### 4.2.B. CpTiCI $_{n}$ Complexes of 3E

Although introduction of $\mathbf{C p}$ ligand to a titanium complex of $\mathbf{3 E}$ would not improve its potential as a olefin polymerization precatalyst, the reaction of ligand 3 E with $\mathrm{CpTiCl}_{3}$ was investigated to gain additional insight into the ligand's titanium coordination chemistry. Three separate reactions were performed between a salt of ligand 3E and one equivalent of $\mathrm{CpTiCl}_{3}$. One started with the in situ preparation of the sodium salt, and the other two started from the magnesium salt that had been separately prepared.

None of the three reactions gave a clean product. The ${ }^{1} \mathrm{H}$ NMR spectra of each crude product and the crystallized material showed a mixture containing several methoxy signals and several Cp signals. High resolution mass spectrometry of the products obtained from the magnesium salt showed a parent peak of $\mathrm{C}_{33} \mathrm{H}_{27} \mathrm{O}_{4} \mathrm{TiCl}$, which corresponds to the mononuclear "CpTiCl" complex 54 (Figure 4.6). Complex 54 is the expected product based on the stoichiometry of the reactions.

Figure 4.6. Mononuclear " CpTiCl complex 54.

X-ray crystallography on a crystal, which was obtained from one of the reactions using the magnesium salt, showed an unexpected structure 53 (Figure 4.7). This structure surprisingly contained one unreacted OH group. An attempt to reproduce this result, however, was not successful. Instead, 'H NMR spectroscopy of the crystallized product was more supportive of the chelating " CpTiCl " complex 54. None of the product mixtures, including the one that yielded the crystal of 53, showed an OH band by IR spectroscopy. We tentatively attribute the formation of complex 53 to incomplete deprotonation of the ligand and slow rotation, which brought the titanium center into reactive proximity to the hydroxy residue.

Figure 4.7. X-ray crystallographic structure of the " $\mathrm{CpTiCl}_{2} / \mathrm{OH}$ " complex 53.
Interatomic distances $(\AA): \mathrm{Ti}-\mathrm{Cl} 1=2.2670(16), \mathrm{Ti}-\mathrm{Cl} 2=2.2490(15), \mathrm{Ti}-\mathrm{Ol}=$ 1.787(3), $\mathrm{Ti}-\mathrm{C} 3=2.341(4), \mathrm{Ti}-\mathrm{C} 4=2.347(4), \mathrm{Ti}-\mathrm{C} 5=2.317(4), \mathrm{Ti} \mathrm{C} 6=2.319(4)$, $\mathrm{Ti}-\mathrm{C} 7=2.332(5), \mathrm{O} 4-\mathrm{H} 3 \mathrm{O}=2.05^{*}, \mathrm{C} 1-\mathrm{C} 2=1.353(5)$. Torsional angles of olefin plane (deg): C11-C1-C2-C31 = -178.6(4), C11-C1-C2-C41 = 1.9(6), C21-C1-C2-C31 = 2.4(6), C21-C1-C2-C41 =-177.1(3). Ring torsion angles (deg): C2-C1$\mathrm{C} 11-\mathrm{Cl} 2=-106.1(4), \mathrm{C} 2-\mathrm{C} 1-\mathrm{Cl1}-\mathrm{C} 16=70.9(5), \mathrm{C} 2-\mathrm{Cl}-\mathrm{C} 21-\mathrm{C} 22=-118.8(4), \mathrm{C} 2-$ $\mathrm{C} 1-\mathrm{C} 21-\mathrm{C} 26=61.2(5), \mathrm{C} 1-\mathrm{C} 2-\mathrm{C} 31-\mathrm{C} 32=72.7(5), \mathrm{C} 1-\mathrm{C} 2-\mathrm{C} 31-\mathrm{C} 36=-110.0(5), \mathrm{C} 1$, C2-C41-C42 = -98.7(4), C1-C2-C41-C46 = 83.2(5).

* Nonbonded distance.

### 4.2.C. $\mathrm{TIBn}_{2}$ Complex of 3 E

The 1:1 reaction of 3 E and $\mathrm{TiBn}_{4}$ produced the mononuclear " $\mathrm{TiBn}_{2}$ " complex 55 cleanly (Scheme 4.9). ${ }^{1} \mathrm{H}$ NMR spectroscopy of this product was consistent with the provided structure, showing a symmetric ligand framework with sharp signals and two identical benzyl groups per ligand. The benzylic methylene protons are split into an AB pattern, consistent with the diastereotopic environment. Crystallization of the product 55, however, was quite difficult, despite the cleanness of the reaction.

Scheme 4.9. Formation of " $\mathrm{TiBn}_{2}$ " complex 55.

The sharpness of the methoxy signal in the ${ }^{1} \mathrm{H}$ NMR spectrum suggests that neither of the two methoxy groups coordinate to the Ti atom, in contrast to the case of " $\mathrm{TiCl}_{2}$ " complex 52 (Section 4.2.A). The metal center has two large benzyl groups, leaving little room for extra dative coordination. The metal center is also more electronically fulfilled than in complex 52, because the benzyl groups are more electrondonating than simple chloride ligands. The relatively upfield chemical shift of the methoxy signal ( 2.82 ppm for $55,3.22 \mathrm{ppm}$ for 52 ) also suggests no coordination to titanium.

The addition of two equivalents of $\mathrm{TiBn}_{4}$ to $\mathbf{3 E}$ did not result in producing a dinuclear " $\left(\mathrm{TiBn}_{3}\right)_{2}$ " complex. Only the mononuclear product 55 and one equivalent of unreacted reagent was observed in the reaction mixture, confirming that the ligand framework of 3E prefers to chelate one metal atom, rather than forming a dinuclear complex.

Chapter 4 4.2. Ti Complexes page 187

Complex 55 may make an interesting cationic complex upon benzyl abstraction, although the possibility of de-methylation (Scheme 4.10) renders this species an unlikely polymerization catalyst.

55

Scheme 4.10. Proposed outcome of a reaction between 55 and $B\left(\mathrm{C}_{6} \mathrm{~F}_{5}\right)_{3}$.

### 4.2.D. TI Chemistry of Ligand $3 Z$

Small-scale reactions with $\mathrm{TiCl}_{4}, \mathrm{TiBn}_{4}$ and $\mathrm{CpTiCl}_{3}$ were performed in the preliminary studies of the coordination behavior of Z-ligand 3Z. The reactivity of the salt of 3 Z toward these titanium reagents was quite different from those of the $E$-isomer 3 E .
i) Reaction with $\mathrm{TiCl}_{4}$. The reaction of the Na salt of ligand 3 Z with one equivalent of $\mathrm{TiCl}_{4}$ resulted in a mixture of compounds. In the ${ }^{\mathbf{}} \mathbf{H}$ NMR spectrum, the major product, labeled 56, showed a symmetrical ligand framework with sharp signals, while the other product(s) showed only broad signals. Sharp signals for coordinated THF, approximately one equivalent per molecule of 56 , were also present.

The reaction with five equivalents of $\mathrm{TiCl}_{4}$, however, resulted in the formation of different products that showed rather broad signals in the ${ }^{1} \mathrm{H}$ NMR spectrum. The signals were not as broad as those of the minor products from the one-equivalent reaction were, nor did they overlap with them. The product was obviously a mixture, given that at least five methoxy signals were observed. The compound that gave the most significant methoxy and corresponding aromatic signals is assigned as 57 . There are approximately two equivalents of coordinated THF per molecule of 57.

Chapter 4 4.2. Ti Complexes page 188

Scheme 4.11 provides the suggested structures of 56 and 57. Compound 56 is drawn as a chelating mononuclear complex and 57 as a non-chelating dinuclear complex. Complex 57 is depicted as an alternating "up/down" structure, which would be a likely conformation to minimize steric crowding.

1 equiv.
$\mathrm{TiCl}_{4}$
$\mathrm{SiCl}_{4}$ equiv.

57

Scheme 4.11. Suggested structures of 56 and 57.

The fact that the additions of one-equivalent and excess $\mathrm{TiCl}_{4}$ gave different products alone suggests that the latter is probably a dinuclear species. Apparently, chelating to one Ti atom is not as favorable as doing so is in the case of ligand 3 E . The ligand geometry of $\mathbf{3 Z}$ is probably less suitable for stabilizing the chelated metal center by the additional coordination of the methoxy groups. This hypothesis is supported by the presence of coordinating THF corresponding to the expected number of titanium centers in both 56 and 57 . Ligand 3 E does not retain any THF under analogous reaction
conditions because it receives internal ether donation (Figure 4.8-a). However, 3Z presumably accepts external THF to stabilize the titanium center (Figure 4.8-b).
(a)

52
(b)

(not preferred)

(preferred)
56

Figure 4.8. Internal and external ether coordination in mononuclear $\mathrm{TiCl}_{2}$ complexes 52 ( $E$-ligand) and 56 ( $Z$-ligand).

The proposed dinuclear structure of $\mathbf{5 7}$ (Scheme 4.11) is further supported by the broadening of the ${ }^{1} \mathrm{H}$ NMR signals, which perhaps comes from the slow rotation of each aryl-ring moiety of the non-rigid structure of 57 . No further data, however, were obtained for 56 and 57 to confirm these suggested structures.
ii) Reaction with $\mathrm{CpTiCl}_{3}$. The reaction of the sodium salt of 3 Z with one equivalent of $\mathrm{CpTiCl}_{3}$ also resulted in a mixture of products, which consists of one major species, a second substantial species, and miscellaneous minor species. Crystallization of the product mixture yielded crystals of dinuclear complex 58, the structure of which was confirmed by X-ray crystallography (Figure 4.9; see Appendix A-22 for details). The ligand conformation is "alternating up/down" to minimize steric congestion.

Figure 4.9. X-ray crystallographic structure of 58.

The formation of dinuclear complex 58, when only one equivalent of $\mathrm{CpTiCl}_{3}$ was used, again suggests that the vicinal pair of hydroxy groups is not ideally situated for chelation. No further attempts were made to optimize the conditions to obtain this compound or to identify other components of the product mixture.
iii) Reaction with $\mathrm{TiBn}_{4}$. The reaction of ligand 3 Z with one equivalent of $\mathrm{TiBn}_{4}$ resulted in a product mixture only sparingly soluble in toluene. The addition of two equivalents of the reagent resulted in a mixture of products, from which mainly unreacted $\mathrm{TiBn}_{4}$ was triturated by toluene. The triturate also contained a small amount of nondiscrete species that showed broad signals in the ${ }^{1} H$ NMR spectrum. Probably intermolecular bridging dominated to form irregular aggregates.

In summary, the vicinal pair of hydroxy groups in $3 Z$ is not ideal to chelate about a single titanium atom to form discrete complexes, especially if the ancillary ligands on the metal fragment are big. No attempts to produce metal complexes of other metals were made for ligand $3 Z$ because of these undesirable coordination preferences and the poor activity obtained in ethylene polymerization reactions by metal derivatives of $\mathbf{3 Z}$ (Chapter 5).

### 4.3. Attempts to Prepare AI/Ti Complexes of Ligand 3E

Due to the unavailability of discrete magnesium complexes of ligand 3 E , attempts to prepare hetero-polymetallic derivatives were limited to the $\mathrm{A} / \mathrm{Ti}$ combination. The basic strategy was to start with the well-characterized Al or Ti species and apply Ti or Al reagents to them, respectively. Preliminary studies of the $\mathrm{Al} / \mathrm{Ti}$ mixed-metal chemistry on ligand 3 E are presented in this section.

### 4.3.A. Reactions of a TI Complex 52 with AI Reagents

The " $\mathrm{TiCl}_{2}$ " complex 52 was used as a starting titanium complex. Additions of $\mathrm{Et}_{3} \mathrm{Al}$ (one and two equivalents) and $\mathrm{Me}_{3} \mathrm{Al}$ (one equivalent) in toluene were performed, and the resulting product or product mixtures were analyzed by ${ }^{\prime} \mathrm{H}$ NMR spectroscopy.
i) Two-equivalent adduct of $\mathrm{Et}_{3} \mathrm{Al}$ : $\mathrm{Al} / \mathrm{Ti}(\mathrm{II})$ complex 59. Among the abovementioned combinations, only the addition of two equivalents of $\mathrm{Et}_{3} \mathrm{Al}$ to 52 resulted in the clean formation of the $\mathrm{Al} / \mathrm{Ti}$ hetero-polymetallic complex 59 (Scheme 4.12). The structure of complex 59 was determined by X-ray crystallography (Figure 4.10).

Scheme 4.12. AI/Ti hetero-polymetallic complex 59.

The titanium atom of complex 59 was formally reduced to Ti (II). The olefin double bond is quite distorted, due to backbonding from the formally $\mathrm{d}^{2} \mathbf{T i}$ atom. The olefin bond length (Cl-C2) is accordingly lengthened to $1.44 \AA$ by this backbonding. ${ }^{2}$

Figure 4.10. X-ray crystallographic structure of the complex 59 with different angle views.
Bond length $(\AA): \mathrm{Cl}-\mathrm{C} 2=1.439(5), \mathrm{Ti}-\mathrm{Cll}=2.6216(13), \mathrm{Ti}-\mathrm{Cl} 2^{*}=3.5064(14), \mathrm{Ti}-\mathrm{Ol}$ $=2.074(3), \mathrm{Ti}-\mathrm{O} 2=2.175(3), \mathrm{Ti}-\mathrm{O} 3=2.073(3), \mathrm{Ti}-\mathrm{O} 4=2.227(3), \mathrm{Ti}-\mathrm{Cl}=2.159(4)$, $\mathrm{Ti}-\mathrm{C} 2=2.150(4)$. Ring torsion angle against $\mathrm{Cl}-\mathrm{C} 2$ bond (deg): $\mathrm{C} 2-\mathrm{C} 1-\mathrm{Cl} 1-\mathrm{Cl} 2=-71.8(5)$, $\mathrm{C} 2-\mathrm{C} 1-\mathrm{C} 11-\mathrm{C} 16=106.1(4), \mathrm{C} 2-\mathrm{C} 1-\mathrm{C} 21-\mathrm{C} 22=112.6(4), \mathrm{C} 2-\mathrm{C} 1-\mathrm{C} 21-\mathrm{C} 26=-69.2(5)$, C1-C2-C31-C32 $=-69.2(5), \mathrm{C} 1-\mathrm{C} 2-\mathrm{C} 31-\mathrm{C} 36=108.8(4), \mathrm{C} 1-\mathrm{C} 2-\mathrm{C} 41-\mathrm{C} 42=114.4(4)$, C1-C2-C41-C46 $=-66.9(5) . \quad$ *Nonbonded distance.

Chapter 4 4.3. ALTi Complexes page 193

The titanium atom takes a pseudo-octahedral geometry, with the four oxygen donors at equatorial positions. The olefin double bond is located at one axial position, while the opposite axial position is filled with the Cl group from one of the terminal " $\mathrm{AlEt}_{2} \mathrm{Cl}$ " units. The $\mathrm{Ti}-\mathrm{Cll}$ interaction was apparently not permanent in solution, for the ${ }^{1} \mathrm{H} /{ }^{13} \mathrm{C}$ NMR spectra in $\mathrm{C}_{6} \mathrm{D}_{6}$ showed a completely symmetrical ligand framework at room temperature. The aryl rings in the solid state structure are tilted from the position perpendicular to the olefin plane, roughly by $15-30^{\circ}$ in a helical way.

With an exception of the Ti-olefin interaction, the structure of the complex 59 has much in common with the dinuclear ( AlEt$)\left(\mathrm{AlEtCl}_{2}\right)$ complex 50 (Figure 4.11). A "core" structure holds one central metal atom (Ti for 59, Al for 50) and one or two aluminum moieties are attached to the core complex at the second lone pair of the aryloxy ligands.

59

50

Figure 4.11. The comparison of the structural features of $\mathbf{5 9}$ and $\mathbf{5 0}$.

The two ethyl groups on each terminal aluminum moiety in 59 appear separately in the ${ }^{1} \mathrm{H}$ NMR spectrum, reflecting the diastereotopicity. The methylene protons on each ethyl group are also diastereotopic, as is reflected in the slightly split quartet signals from a $\mathrm{ABX}_{3}$ pattern. The chemical shifts of the ethyl signals are all close to the normal region for ethyl aluminum reagents (see Section 4.1.A-i). The chemical shifts are also similar to those of the terminal " $\mathrm{AlEtCl}_{2}$ " moiety in the structurally similar complex 50.

A sharp singlet from the two methoxy groups of 59 appears at 3.96 ppm , which is considerably more downfield than what was observed in other previously discussed complexes. For example, complex 52 (the starting material) shows a methoxy signal at 3.17 ppm ; at lower temperature, two differentiated methoxy signals are observed at 3.24 and $3.03 \mathrm{ppm}\left(-60^{\circ} \mathrm{C}\right)$, still in a "normal" region for the methoxy groups of the ligand
system. The structurally similar dinuclear aluminum complex $\mathbf{5 0}$ gives methoxy signals at 3.17 and 2.65 ppm .

The strongly downfield shift of the methoxy signal in complex 59 probably comes from stronger donation to the titanium atom. A comparison of the electron count of complexes 52 and 59 may provide a reasonable explanation (Table 4.1). While both formally count as fourteen-electron metal centers, complex 59 has fewer anionic donors and no $\pi$-donation of lone pair electrons from the aryloxy anions: these lone pairs are used to bind the aluminum units. The deficiency of electrons requires stronger donation from both neutral methoxy groups, as well as from the chloride bridge and the olefin $\pi$ electrons.

Table 4.1. Comparison of the electron counting for 52 and 59.

ii) Reaction of 52 with one equivalent of $\mathrm{Et}_{3} \mathrm{Al}$. The addition of only one equivalent of $\mathrm{Et}_{3} \mathrm{Al}$ to 52 resulted in a mixture of three compounds: $\mathrm{M}, \mathrm{N}$ and 59 in the ratio of $6: 1$ $: 0.9$. Because the ratio was determined by the relative integral of the methoxy signals in the ${ }^{1} H$ NMR spectrum $\left(C_{6} D_{6}\right)$, it reflects only soluble species. Some degree of cloudiness

Chapter 4 4.3. ALTi Complexes page 195
of the solution was noted in the preparation of the $\mathrm{C}_{6} \mathrm{D}_{6}$ solution, which eventually separated and precipitated. The real ratio of the components, therefore, may be different from the observed ratio.

The dominant product $\mathbf{M}$ is an unsymmetrical species with two different methoxy groups, both of which are quite downfield ( 4.16 \& 3.96 ppm ). Three different ethyl groups belong to $\mathbf{M}$. From these observations and the reaction condition, the plausible structure of $\mathbf{M}$ is suggested to be a $1: 1$ adduct of 52 and $E t_{3} \mathrm{Al}$, accompanied by a $\mathrm{Cl} / \mathrm{Et}$ exchange (Scheme 4.13). This same scheme portrays the addition of a second equivalent of $\mathrm{Et}_{3} \mathrm{Al}$ to M and the mechanism that results in the two-equivalent adduct 59 .

$\qquad$

Scheme 4.13. Proposed mechanism of the formation of 59.

In this proposed mechanism, as soon as the first molecule of $\mathrm{Et}_{3} \mathrm{Al}$ approaches complex 52, an exchange of the aluminum-bound ethyl for titanium-bound chloride occurs. The second $E t_{3} \mathrm{Al}$ molecule does the same: the resulting "Ti(IV)Et ${ }_{2}$ " species goes through a $\beta$-hydride elimination of ethene, followed by reductive elimination of ethane, to give 59. The driving force for the reductive elimination may be the steric crowding from the terminal " $\mathrm{AlEt}_{2} \mathrm{Cl}^{\prime}$ groups or simply the irreversible loss of volatile ethene and ethane. This mechanism involves the formation of gaseous ethene and ethane, although no gas evolution was observed in the actual reaction, probably due to the small scale (<10 mg of the starting material). Detection and quantification of the proposed byproducts were not pursued.

The minor byproduct N in the $1: 1$ reaction of 52 and $\mathrm{Et}_{3} \mathrm{Al}$ showed a symmetrical ligand framework in the ${ }^{1} \mathrm{H}$ NMR spectrum, to which two equivalent ethyl groups probably belong. Within each ethyl group, the signals are slightly split, indicating a diastereotopic environment. These ethyl groups are assigned to terminally attached aluminum moieties. The single methoxy signal is quite downfield ( 4.18 ppm ). The slight broadness of the methoxy group may suggest that one methoxy group coordinates to a metal atom, but exchanges reasonably fast with another on the NMR time scale. These spectroscopic features narrow down the possibilities for $\mathbf{N}$ to a few structures, such as $\mathbf{N}_{\mathbf{a}}$ and $\mathbf{N}_{\mathrm{b}}$, presented in Figure 4.12.
$\mathbf{N}_{\mathbf{a}}$ is analogous to the Ti (II) complex 59 , while $\mathbf{N}_{b}$ is analogous to the starting $\mathrm{Ti}(\mathrm{IV})$ complex 52. Considering the limited number of chlorides in the reaction system, $\mathbf{N}_{\mathbf{a}}$ may be the better candidate. The compound $\mathbf{N}_{\mathbf{a}}$ could form if the overreaction byproduct 59 (in 1:1 reaction) further exchanges its aluminum-bound ethyl groups with the titanium-bound chlorides of the unreacted starting material 52. Such AI-Et/Ti-Cl exchange should be favorable thermodynamically. If so, $\mathbf{5 2}$ must also be transformed into a mononuclear " $\mathrm{TiEt}_{2}$ " complex, although no such species has been detected. It is still possible, however, that the " $\mathrm{TiEt}_{2}$ " complex further decomposes to something insoluble and thus is not detected by ${ }^{1} \mathrm{H}$ NMR spectroscopy.

$\mathrm{N}_{\mathrm{a}}$

$\mathrm{N}_{\mathrm{b}}$

Figure 4.12. Suggested structures of $\mathbf{N}$.
Chapter 4 4.3. AUTi Complexes page 197
iv) Reaction of 52 with one equivalent of $\mathrm{Me}_{3} \mathrm{Al}$. The addition of $\mathrm{Me}_{3} \mathrm{Al}$ (one equivalent) to 52 was fairly clean, producing one major product $L$ with a symmetric ligand framework. The 'H NMR spectrum showed one titanium-bound methyl group ( 2.18 ppm ) and a broad methoxy signal in a normal region ( 3.03 ppm ).

One possibility is that $\mathbf{L}$ is a mononuclear " TiMeCl " complex, formed by exchange as illustrated Scheme 4.14. In this proposed mechanism, the terminal " $\mathrm{AlMe}_{2} \mathrm{Cl}$ " moiety in the stage $\mathrm{M}^{\prime}$, analogous to $\mathbf{M}$ in Scheme $\mathbf{4 . 1 3}$ does not remain bound to the core molecule. Once dissociated, $\mathrm{AlMe}_{2} \mathrm{Cl}$ self-aggregates so the reverse reaction does not compete. It is not certain, however, why the " $\mathrm{AlEt}_{2} \mathrm{Cl}^{\prime}$ moiety in $\mathbf{M}$ remained intact on the core molecule, while the " $\mathrm{AlMe}_{2} \mathrm{Cl}^{\prime}$ moiety in $\mathrm{M}^{\prime}$ did not.

Scheme 4.14. Proposed structure of $L$ formed from the reaction between 52 and $\mathrm{Me}_{3} \mathrm{Al}$.

### 4.3.B. Reactions of AI Complexes with $\mathrm{TiCl}_{4}$

$\mathrm{TiCl}_{4}$ was the only titanium reagent used in these attempts. The two aluminum complexes used were the mononuclear "AIEt" complex 47 and the ( AIEt )( $\mathrm{AlEt}_{3}$ ) complex 48 that partly dissociates in solution. The results of the reactions between 47 or 48 and $\mathrm{TiCl}_{4}$ (one or two equivalents) are summarized in Scheme 4.15.

Scheme 4.15. Reactions between 47 or 48 and $\mathrm{TiCl}_{4}$.

The addition of one equivalent of $\mathrm{TiCl}_{4}$ to the mononuclear "AIEt" complex 47 cleanly produced the previously characterized mononuclear " $\mathrm{TiCl}_{2}$ " complex 52 . No aluminum moiety remained intact.

Complex 48 was not the best choice as a starting material for further experiments, because of the dissociation behavior in solution (see Scheme 4.15). The addition of two equivalents of $\mathrm{TiCl}_{4}$ to $\mathbf{4 8}$ resulted in toluene-insoluble material. The solution in THF- $\mathrm{d}_{8}$

Chapter 4 4.3. ALTi Complexes page 199
or $\mathrm{CD}_{3} \mathrm{CN}$ provided only broad signals in ${ }^{1} \mathrm{H}$ NMR spectroscopy. No further investigation was done for this case.

The reaction of 48 with one equivalent of $\mathrm{TiCl}_{4}$, however, resulted in a mixture of three compounds: $\mathbf{N}, \mathbf{M}$ and $\mathbf{5 0}$ (compound $\mathbf{N}$ is depicted as $\mathbf{N}_{\mathbf{a}}$ in Scheme 4.15). The two major products $\mathbf{N}$ and $\mathbf{M}$ were also found in the previously discussed addition of $\mathrm{Et}_{3} \mathrm{Al}$ (one equivalent) to the titanium complex 52. The minor dialuminum complex 50 was crystallographically characterized and discussed in Section 4.1.B.

The proposed mechanism for the formation of these tentatively assigned species is presented in Scheme 4.16. The formation of $\mathbf{N}$ and $\mathbf{M}$ as major species suggests that the central aluminum atom is promptly replaced by a titanium atom. The minor product 50 can form if two of the ethyl groups on the terminal aluminum are simply replaced by the chlorides from $\mathrm{TiCl}_{4}$.

$\downarrow \mathrm{TiCl}_{4}$

Scheme 4.16. Proposed mechanism of the reaction between 48 and one equivalent of $\mathrm{TiCl}_{4}$.

### 4.4. Conclusion

The aluminum and titanium complexes derived from ligand 3E showed both mono- and polynuclear structures. Some common features were noted in the structurally characterized polymetallic species: (i) a central (core) metal atom, either Al or Ti , and (ii) when applicable, one or two terminal metal Al moieties attached via the lone pair of aryloxy anionic oxygen donors coordinated to the central metal atom.

The flexible role of the methoxy donor groups was also noteworthy. Depending on the demand from the metal at the central position and the steric environment, two, one, or none of the methoxy groups were used as required. When binding was unnecessary, they could rotate away to avoid steric crowding. The coordination of the methoxy groups also served to protect the otherwise exposed central metal atom, such as the $\mathrm{Ti}(\mathrm{II})$ atom in the hetero-polymetallic complex 59.

The comparison of $E$-ligand 3 E and $Z$-ligand $3 Z$ in coordination behavior showed that dialkylation of the tetrahydroxy system in the alternating pattern, as in 3 E , provided a good chelating dianionic ligand framework.

### 4.5. Experimental

Instrumental, General and Materials: see Chapter 3, Section 3.4 Experimental.

Note: " $E$ - or $\mathrm{Z}-\left\{\mathrm{C}_{28} \mathrm{H}_{22} \mathrm{O}_{4}\right\}$ " represents the fully deprotonated ligand 3 E or 3 Z i.e., $[3 \mathrm{E}$ $\mathbf{2 H}]$ or $[3 \mathrm{Z}-\mathbf{2 H}]$ (see below). The conformation is not restricted to the "all-up" form.

47: $E-\left\{\mathrm{C}_{\mathbf{2 8}} \mathrm{H}_{\mathbf{2 2}} \mathrm{O}_{4}\right\}$ (AlEt)

To a suspension of $E$-bis(2-hydroxyphenyl)-bis(2-methoxyphenyl)ethene (3E) $(0.0734 \mathrm{~g}$, $0.173 \mathrm{mmol})$ in 0.5 mL of toluene was slowly added $\mathrm{Et}_{3} \mathrm{Al}(0.0201 \mathrm{~g}, 0.176 \mathrm{mmol})$ dissolved in 1.5 mL of toluene at room temperature. The mixture became a solution within 2 min . Gas evolution was not obvious. After overnight, the volatiles were removed to give a partly crystalline residue. A small amount of toluene was added to dissolve the less crystalline material (but leaving some crystals undissolved), hexane was layered on top for slow diffusion, and the mixture was cooled to $-30{ }^{\circ} \mathrm{C}$ for crystallization. The crystals were removed from the mother liquor, washed with small amount of pentane, and dried in vacuo. The crystals amounted to $0.0597 \mathrm{~g}(72 \%)$. The mother liquor and the washings were collected and evaporated to leave a shiny crystalline residue, which was also quite pure product ( $0.0221 \mathrm{~g}, 27 \%$ ). ${ }^{1} \mathrm{H} \operatorname{NMR}\left(360 \mathrm{MHz}, \mathrm{C}_{6} \mathrm{D}_{6}\right): \delta 7.12(2 \mathrm{H}, \mathrm{br} \mathrm{d}, \mathrm{J}=$ $\sim 7 \mathrm{~Hz}), 7.07(2 \mathrm{H}$, slightly br dd, $J=7.5,1.8 \mathrm{~Hz}), 6.89(2 \mathrm{H}$, ddd, $J=8,7,1.8 \mathrm{~Hz}), 6.80$ ( $2 \mathrm{H}, \mathrm{dd}, J=8, \sim 1 \mathrm{~Hz}$ ), $6.72(2 \mathrm{H}$, slightly br td, $J=8, \sim 1.8 \mathrm{~Hz}), 6.65(2 \mathrm{H}, \mathrm{td}, J=7.5, \sim 1$

Anal. Calcd for $\mathrm{C}_{30} \mathrm{H}_{27} \mathrm{AlO}_{4}$ : C, 75.90; H, 5.69. Found: C, 75.49; H, 5.58. X-ray crystallography: see Appendix A-17. The X-ray analyzed crystals were obtained by slow crystallization of 48 from toluene-hexanes (slow diffusion, r.t. $\rightarrow-30^{\circ} \mathrm{C}$ ).

48: $E-\left\{\mathrm{C}_{28} \mathrm{H}_{22} \mathrm{O}_{4}\right\} \cdot \mathrm{Al}_{\mathbf{2}} \cdot \mathrm{Et}_{4}$

3E

To the stirred suspension of $E$-bis(2-hydroxyphenyl)-bis(2-methoxyphenyl)ethene (3E) ( $0.1254 \mathrm{~g}, 0.295 \mathrm{mmol}$ ) in 2 mL of toluene was added $\mathrm{Et}_{3} \mathrm{Al}(0.0741 \mathrm{~g}, 0.649 \mathrm{mmol})$ dissolved in 1 mL of toluene at room temperature. Gas evolution was observed within 1 min . and the mixture became a solution within 40 min . After 20 h , the solution was concentrated in vacuo until it became slightly cloudy. Hexane was layered on top and the two-phase mixture was cooled to $-30^{\circ} \mathrm{C}$. The white precipitate (not crystalline) was collected, washed with cold pentane, and dried in vacuo. The elemental analysis (C/H) was consistent with the composition of the dialuminum product 48: $\mathrm{C}_{28} \mathrm{H}_{22} \mathrm{O}_{4} \mathrm{Al}_{2}\left(\mathrm{C}_{2} \mathrm{H}_{5}\right)_{4}$. The ${ }^{1} \mathrm{H}$ NMR spectrum at room temperature showed broad signals. From the recrystallization of this material from layered toluene-hexanes at $-30^{\circ} \mathrm{C}$, clear prism crystals were produced on the vial wall in the hexane layer, as well as some noncrystalline solid between the solvent layers. The crystals were found to be the monoaluminum product 47 , confirmed by ${ }^{1} H$ NMR spectroscopy and X-ray crystallography. Complex 48 : ${ }^{1} \mathrm{H}$ NMR ( $400 \mathrm{MHz}, \mathrm{C}_{6} \mathrm{D}_{6}, 75^{\circ} \mathrm{C}$ ): $\delta 7.19(2 \mathrm{H}$, slightly br

## 49: $\boldsymbol{E}-\left\{\mathrm{C}_{28} \mathrm{H}_{22} \mathrm{O}_{4}\right\}(\mathrm{AlCl})$

$3 E$

To a suspension of $E$-bis(2-hydroxyphenyl)-bis(2-methoxyphenyl)ethene ( 3 E ) ( 0.0098 g , 0.023 mmol ) in 0.5 mL of toluene was quickly added $\mathrm{Et}_{2} \mathrm{AlCl}(0.0028 \mathrm{~g}, 0.023 \mathrm{mmol})$ dissolved in 1.5 mL of toluene at room temperature. Gas evolution was not obvious. The cloudy mixture became clear over 30 min . After overnight, the mixture became cloudy again. The volatiles were removed, and the residue was analyzed by ${ }^{1} H$ NMR spectroscopy in $\mathrm{CD}_{3} \mathrm{CN}$ and mass spectrometry. Both were consistent with the proposed structure of 49. When a more concentrated solution was prepared in $\mathrm{CD}_{3} \mathrm{CN}$ (as a supernatant with a considerable amount of undissolved portion), ${ }^{1} \mathrm{H}$ NMR spectroscopy showed a mixture of two symmetrical species ( 49 and X ).
49. 'H NMR ( $360 \mathrm{MHz}, \mathrm{CD}_{3} \mathrm{CN}$ ): $\delta 7.20(2 \mathrm{H}, \mathrm{dd}, J=7.8,1.8 \mathrm{~Hz}), 7.11(2 \mathrm{H}$, ddd, $J=$ $8 \sim 8.5,7.5,1.8 \mathrm{~Hz}), 7.10(2 \mathrm{H}, \mathrm{dd}, J=7.5,1.8 \mathrm{~Hz}), 6.94(2 \mathrm{H}, \mathrm{ddd}, J=8,7.5,1.8 \mathrm{~Hz}), 6.79$ $(2 \mathrm{H}, \mathrm{d}, J=8 \mathrm{~Hz}), 6.77(2 \mathrm{H}, \mathrm{dd}, J=7,1.2 \mathrm{~Hz}), 6.63(2 \mathrm{H}, \mathrm{td}, J=7.5,1.2 \mathrm{~Hz}), 6.60(2 \mathrm{H}$, dd, $J=7,1.2 \mathrm{~Hz}$ ), $3.72\left(6 \mathrm{H}, \mathrm{s}, \mathrm{OCH}_{3}\right)$. HRMS (EI) $\mathrm{m} / \mathrm{z}$ : Calcd for $\mathrm{C}_{28} \mathrm{H}_{22} \mathrm{AlClO}_{4}$ : 484.10220. Found: 484.10019 ( $100 \%$ ) [ $\left.\mathrm{M}^{+}\right]$.
X. 'H NMR ( $360 \mathrm{MHz}, \mathrm{CD}_{3} \mathrm{CN}$ ): $\sim 7.18(2 \mathrm{H}+2 \mathrm{H}$, overlapping), $\sim 7.10(2 \mathrm{H}) 6.98(2 \mathrm{H}, \mathrm{br})$, $\sim 6.96(2 \mathrm{H}, \mathrm{br}), 6.92(2 \mathrm{H}$, ddd, $J=8,7.3,1.8 \mathrm{~Hz}), 6.59(2 \mathrm{H}, \mathrm{td}, J=-7.5,1 \mathrm{~Hz}), 6.50(2 \mathrm{H}$, br d, $J=8 \mathrm{~Hz}$ ), 3.68 ( $6 \mathrm{H}, \mathrm{br} \mathrm{s}, \mathrm{OMe}$ ).

## 50: $E-\left\{\mathrm{C}_{38} \mathrm{H}_{2} \mathrm{O}_{4}\right\}(\mathrm{AlEt})\left(\mathrm{AlEtCl}_{2}\right)$

3E

toluene

To a suspension of $E$-bis(2-hydroxyphenyl)-bis(2-methoxyphenyl)ethene ( 3 E ) $\mathbf{( 0 . 0 3 8 6 \mathrm { g } \text { , }}$ $0.0909 \mathrm{mmol})$ in 0.5 mL of toluene was quickly added $\mathrm{Et}_{2} \mathrm{AlCl}(0.0220 \mathrm{~g}, 0.182 \mathrm{mmol})$ dissolved in 1.5 mL of toluene at room temperature. Gas evolution was not obvious. The cloudy mixture gradually turned clearer. After overnight, the volatiles were removed from the still slightly cloudy mixture. ${ }^{1} \mathrm{H}$ NMR spectroscopy of the crude product showed a mixture of 50 and 49 in a $7.4: 1$ ratio. The crude product was redissolved in toluene, filtered through a celite-packed pipette, and the filtrate warmed and then allowed to cool to room temperature. Some crystals formed. Pentane was layered on the toluene solution for slow diffusion, and the mixture was cooled to $-30^{\circ} \mathrm{C}$. The crystals that formed were removed from the mother liquor, washed with pentane, and dried in vacuo to give reasonably pure product ( $0.0404 \mathrm{~g}, 73 \%$ ). The ${ }^{1} \mathrm{H}$ NMR spectrum of the product showed a mixture of $50: 49$ in a $11: 1$ ratio ( $8 \%$ of 49 ). ${ }^{1} \mathrm{H}$ NMR ( $400 \mathrm{MHz}, \mathrm{C}_{6} \mathrm{D}_{6}$ ): $\delta 7.73$ ( 1 H , br d, $J=\sim 8 \mathrm{~Hz}$ ), $7.47(1 \mathrm{H}$, br d, $J=8 \mathrm{~Hz}) 7.22(1 \mathrm{H}, \mathrm{brd}, J=\sim 7 \mathrm{~Hz}), 7.09(1 \mathrm{H}$, br d, $J=$ $8 \mathrm{~Hz}), 6.92(1 \mathrm{H}, \mathrm{br} \mathrm{d}, J=\sim 7 \mathrm{~Hz}), 6.79 \sim 6.70(5 \mathrm{H}$, overlapping), 6.56~6.49(3H, overlapping), $6.29(1 \mathrm{H}, \mathrm{br} \mathrm{d}, J=8 \mathrm{~Hz}), 6.11(1 \mathrm{H}$, slightly br dd, $J=7.5,1.8 \mathrm{~Hz}), 3.13$ $\left(3 \mathrm{H}, \mathrm{s}, \mathrm{OCH}_{3}\right), 2.63\left(3 \mathrm{H}, \mathrm{s}, \mathrm{O}^{\prime} \mathrm{CH}_{3}\right), 1.50\left(3 \mathrm{H}, \mathrm{t}, J=8 \mathrm{~Hz}, \mathrm{AlCH}_{2} \mathrm{CH}_{3}\right), 1.23(1 \mathrm{H}, \mathrm{m}$, $\left.\mathrm{AlCH}_{4} \mathrm{H}_{\mathrm{b}} \mathrm{CH}_{3}\right), 1.2\left(3 \mathrm{H}\right.$, br $\left.\mathrm{t}, J=\sim 7.5 \mathrm{~Hz}, \mathrm{AlC}^{\prime} \mathrm{H}_{2} \mathrm{C}^{\prime} \underline{H}_{3}\right), 0.72\left(1 \mathrm{H}, \mathrm{m}, \mathrm{AlCH}_{2} \mathrm{H}_{\mathrm{k}} \mathrm{CH}_{3}\right)$, $\left.-0.62\left(1 \mathrm{H}, \mathrm{br}, \mathrm{AlC}^{2} \mathrm{H}_{2} \mathrm{H}_{6} \mathrm{C}^{\prime} \mathrm{H}_{3}\right),-0.86\left(1 \mathrm{H}, \mathrm{br}, \mathrm{AlC}^{\prime} \mathrm{H}_{2} \mathrm{H}_{\mathrm{R}} \mathrm{C}^{\prime} \mathrm{H}_{3}\right) .{ }^{13} \mathrm{C} \mathrm{NMR} \mathrm{(75MHz}, \mathrm{C}_{6} \mathrm{D}_{6}\right)$ : ס 156.4, 155.4, 153.7, 150.0, 141.3, 137.1, 135.1, 133.7, 133.5, 133.3, 133.0, 130.5, 130.4, 129.7, 129.3, 129.0, 128.7, 128.5, 126.7, 123.9, 121.7, 120.2, 120.0, 119.2, 117.6, $110.5,63.0(\mathrm{OMe}), 54.3(\mathrm{OMe}), 9.4\left(\mathrm{AlCH}_{2} \mathrm{CH}_{3}\right), 8.8\left(\mathrm{AlCH}_{2} \mathrm{CH}_{3}\right), 1.8\left(\mathrm{AlCH}_{2} \mathrm{CH}_{3}\right)$, $0.11\left(\mathrm{AlCH}_{2} \mathrm{CH}_{3}\right)$. 3E

53
(1) From the Mg salt -1. A magnesium salt, $E-\left\{\mathrm{C}_{28} \mathrm{H}_{22} \mathrm{O}_{4}\right\} \cdot \mathrm{Mg}$ ( $\mathrm{FW}=441$ ), was prepared by mixing $\mathbf{3 E}(0.1665 \mathrm{~g}, \mathbf{0 . 3 9 2 2} \mathrm{mmol})$ and $\mathrm{CH}_{3} \mathrm{MgCl}(0.3 \mathrm{M} / \mathrm{THF}, 2.6 \mathrm{~mL}, 0.78$ mmol ) in 1 mL of THF overnight, collecting the precipitate, washing with THF, and drying. The formula weight (FW) was calculated based on the C/H analysis (see Chapter 5, Section 5.4.B). The magnesium salt ( $0.0135 \mathrm{~g}, 0.0306 \mathrm{mmol}$ ) and $\mathrm{CpTiCl}_{3}(0.0053 \mathrm{~g}$, 0.024 mmol ) were mixed in 1.5 mL of toluene for two days. The bright orange, slightly cloudy solution was filtered through a celite-packed pipette, and the volatiles were removed from the filtrate in vacuo. ${ }^{1} \mathrm{H}$ NMR spectroscopy of the residue showed a mixture of many species, containing the signals assigned to 54 (see below). Crystallization of the residue from toluene-hexanes (r.t. $\rightarrow-30^{\circ} \mathrm{C}$ ) yielded orange-red prism crystals among powder with a lighter color. X-ray crystallography showed the structure of 53, but the HRMS result of the crude product was suggestive of 54. HRMS (EI): Calcd for $\mathrm{C}_{33} \mathrm{H}_{27} \mathrm{O}_{4} \mathrm{ClTi}$ : 570.10974 . Found: 570.10899 ( $31 \%$ ) [ $\left.\mathrm{M}^{+}\right]$, 505.06751 ( $100 \%$ ) $\left[\mathrm{M}-\mathrm{C}_{5} \mathrm{H}_{5}\right]^{+}$.
(2) From the $\mathbf{M g}$ salt -2. The magnesium salt ( $0.1002 \mathrm{~g}, 0.227 \mathrm{mmol}$ ) and $\mathrm{CpTiCl}_{3}$ ( $0.0507 \mathrm{~g}, 0.231 \mathrm{mmol}$ ) were mixed in 5 mL of toluene for four days. The bright orange, cloudy mixture was filtered through a celite-packed pipette, and the volatiles were removed from the filtrate in vacuo. The residue $(0.1252 \mathrm{~g})$ was crystallized from toluenehexanes (r.t. $\rightarrow-30^{\circ} \mathrm{C}$ ). The partly crystalline but mostly powdery solid was separated

Chapter 4 4.5. Experimental page 208
from the mother liquor and dried in vacuo ( $0.0462 \mathrm{~g}, 36 \%$ if it is exclusively 54 ). The powder showed the cleanest ${ }^{\mathbf{1}} \mathrm{H}$ NMR spectrum suggestive of 54 , not 53 . The HRMS result was similar to that of (1), also suggestive of 54.
(3) From the Na salt. The phenolic ligand 3 E ( $0.0295 \mathrm{~g}, 0.0695 \mathrm{mmol}$ ) was mixed with $\mathrm{NaH}(\mathbf{0 . 0 0 3 5} \mathrm{g}, 0.146 \mathrm{mmol})$ in 1 mL of THF. Gas evolution was not obvious. After 3.5 h of stirring, the volatiles were removed, then the residue was suspended in toluene ( 1 $\mathrm{mL})$. To this suspension was added $\mathrm{CpTiCl}_{3}(0.0226 \mathrm{~g}, 0.103 \mathrm{mmol})$ dissolved in 1 mL of toluene. The color turned to yellow-orange. After 1.5 h , the volatiles were removed in vacuo, then the residue was triturated with toluene, filtered through a celite-packed pipette, and the volatiles were removed from the filtrate. The residue showed a mixture of many species in the ${ }^{1} \mathrm{H}$ NMR spectrum $\left(\mathrm{C}_{6} \mathrm{D}_{6}\right)$, including signals assigned to 54.
53: X-ray crystallography: see Appendix A-20.
54 (impure): 'H NMR ( $360 \mathrm{MHz}, \mathrm{C}_{6} \mathrm{D}_{6}$ ): $\delta 7.07(2 \mathrm{H}, \mathrm{br} \mathrm{d}, J=8 \mathrm{~Hz}), 6.87(2 \mathrm{H}, \mathrm{dd}, J=8$, $1.5 \mathrm{~Hz}), 6.83(2 \mathrm{H}, ~ ' t d ', ~ J=$ unclear due to overlapping), $6.81(2 \mathrm{H}, \mathrm{d} ?, J=$ ?, 1.8 Hz$), 6.67$ ( $2 \mathrm{H}, \mathrm{td}, J=6.5,1 \mathrm{~Hz}$ ), $6.66(2 \mathrm{H}, \mathrm{br}), 6.27(2 \mathrm{H}, \mathrm{br} \mathrm{d}, J=8 \mathrm{~Hz}), 6.22(2.5 \mathrm{H}$ ?, s, the largest Cp signal, but not enough), $3.21\left(6 \mathrm{H}, \mathrm{s}, \mathrm{OCH}_{3}\right)$.

## 55: $E-\left\{\mathrm{C}_{23} \mathrm{H}_{22} \mathrm{O}_{4}\right\}\left(\mathrm{TiBn}_{2}\right)$

3E

55

To a suspension of $E$-bis(2-hydroxyphenyl)-bis(2-methoxyphenyl)ethene (3E) ( 0.1616 g , 0.3807 mmol ) in toluene ( 1 mL ) was added $\mathrm{TiBn}_{4}(0.1585 \mathrm{~g}, 0.3843 \mathrm{mmol})$ dissolved in 2 mL of toluene. After stirring the mixture overnight, the volatiles were removed in vacuo to leave dark brown-red residue. 'H NMR spectroscopy of the crude product showed clean 55 with a trace amount of $\mathrm{TiBn}_{4}$. Crystallization attempts from toluene or toluene-hexanes were not successful. The compound was too reactive to allow for mass spectrometric analysis. ${ }^{1} \mathrm{H}$ NMR ( $360 \mathrm{MHz}, \mathrm{C}_{6} \mathrm{D}_{6}$ ): $\boldsymbol{\delta} \sim 7.25$ ( 4 H , overlapping), 7.15~6.95 ( 14 H , overlapping), $6.69(4 \mathrm{H}, \mathrm{td}, J=7.5,1.2 \mathrm{~Hz}), 6.53(2 \mathrm{H}, \mathrm{td}, J=7.5,1 \mathrm{~Hz}), 6.15(2 \mathrm{H}$, dd, $J=8,1 \mathrm{~Hz}) 3.17(2 \mathrm{H}, \mathrm{d}, J=10.5 \mathrm{~Hz}$ ), $3.09(2 \mathrm{H}, \mathrm{d}, J=10.5 \mathrm{~Hz}), 2.82$ ( $6 \mathrm{H}, \mathrm{s}, \mathrm{OMe}$ ).

## 56: $\mathrm{Z}-\left\{\mathrm{C}_{25} \mathrm{H}_{22} \mathrm{O}_{4}\right\}\left[\mathrm{TiCl}_{2}\right.$ (thf)]? (impure)

To a solution of Z-bis(2-benzyloxyphenyl)-bis(2-methoxyphenyl)ethene (3Z) ( 0.0507 g , 0.119 mmol ) in 1 mL of THF was added $\mathrm{NaH}(0.0059 \mathrm{~g}, 0.25 \mathrm{mmol})$ suspended in 1 mL of THF. Gas evolution was observed immediately. The mixture became cloudier within several minutes. After stirring 4 h , the volatiles were removed in vacuo and the residue was suspended in 1 mL of toluene. $\mathrm{TiCl}_{4}(0.0257 \mathrm{~g}, 0.135 \mathrm{mmol})$ dissolved in 1 mL of toluene was then added. The color immediately turned dark red. After stirring overnight, the volatiles were removed in vacuo and the residue was triturated with toluene. The triturate was filtered through a celite-packed pipette and evaporated to dryness. The ${ }^{1} \mathrm{H}$ NMR spectrum of the residue showed a mixture of 56 and other material(s) that show broad signals. The structure of 56 was only tentatively assigned (see Section 4.2.D). ${ }^{1} \mathrm{H}$ NMR ( $360 \mathrm{~Hz}, \mathrm{C}_{6} \mathrm{D}_{6}$ ): $\boldsymbol{\delta} 7.31(2 \mathrm{H}$, br d, $J=\sim 7 \mathrm{~Hz}$ ), $6.90 \sim 6.87$ ( 4 H ?), 6.71 ( 2 H , dd, $J=$ $7.5,1.8 \mathrm{~Hz}), 6.69 \sim 6.63(6 \mathrm{H}$ ), 6.64 ( $2 \mathrm{H}, \mathrm{td}, J=7.3,1.5 \mathrm{~Hz}$ ), 6.36 ( 2 H , slightly br d, $J=8$ Hz ), 4.06 ( $4 \mathrm{H}, \mathrm{m}, \mathrm{THF}-\alpha$ ), 3.20 ( $6 \mathrm{H}, \mathrm{s}, \mathrm{OMe}$ ), 1.27 ( $4 \mathrm{H}, \mathrm{m}, \mathrm{THF}-\beta$ ).

## 57: $\mathrm{Z}-\left\{\mathrm{C}_{28} \mathrm{H}_{22} \mathrm{O}_{4}\right\}\left[\mathrm{TiCl}_{3} \text { (thf) }\right]_{2}$ ? (impure)

The procedure is the same as above, except for the quantity of the materials. 3 Z ( 0.0167 $\mathrm{g}, 0.0393 \mathrm{mmol}), \mathrm{NaH}(0.0020 \mathrm{~g}, 0.083 \mathrm{mmol})$ and $\mathrm{TiCl}_{4}(0.0369 \mathrm{~g}, 0.195 \mathrm{mmol})$ were used. The structure of 56 was only tentatively assigned (see Section 4.2.D). ${ }^{1} \mathrm{H}$ NMR spectroscopy of $57\left(360 \mathrm{~Hz}, \mathrm{C}_{6} \mathrm{D}_{6}\right)$ : aromatic region is unclear due to broadness of signals and overlapping; $\delta 3.82$ ( 8 H ?, br, THF- $\alpha$ ), 3.24 ( $6 \mathrm{H}, \mathrm{br} \mathrm{s}, \mathrm{OMe}$ ), 1.05 ( 8 H ?, br, THF- $\beta$ ). The dinuclear structure was tentatively proposed as one possibility consistent with the limited 'H NMR spectroscopic information (Section 4.2.D).

## 58: $\mathbf{Z}-\left\{\mathrm{C}_{28} \mathbf{H}_{\mathbf{2 2}} \mathrm{O}_{\mathbf{4}}\right\}\left(\mathrm{CpTiCl}_{2}\right)_{\mathbf{2}}$

Chapter 4 4.5. Experimental page 210

To a suspension of Z-bis(2-benzyloxyphenyl)-bis(2-methoxyphenyl)ethene (3Z) (0.0244 $\mathrm{g}, 0.0575 \mathrm{mmol}$ ) in 1 mL of toluene was added $\mathrm{NaH}(0.0031 \mathrm{~g}, 0.13 \mathrm{mmol})$ suspended in 1 mL of toluene. Immediate gas evolution was observed. The mixture became clear within 5 min , then turned cloudy again. After stirring for $2.5 \mathrm{~h}, \mathrm{CpTiCl}_{3}$ ( 0.0126 g , 0.0575 mmol ) was added in 1 mL of toluene. The color turned yellow-orange, as the mixture became almost homogeneous. After 3 h , the volatiles were removed in vacuo, the residue was triturated with toluene, filtered through a celite-packed pipette, and the filtrate was evaporated in vacuo to dryness. 'H NMR spectroscopy of this residue showed sharp signals of a mixture, with a $2: 1: 2: 1$ ratio of methoxy singlets. The residue was only partially soluble in toluene. Crystallization of the toluene-soluble portion from toluene yielded single crystals analyzed by X-ray crystallography as 58. The yield was not recorded. ${ }^{1} \mathrm{H}$ NMR spectroscopy of the major species $\left(360 \mathrm{~Hz}, \mathrm{C}_{6} \mathrm{D}_{6}\right): \boldsymbol{\delta} 7.84(1 \mathrm{H}, \mathrm{br})$, $7.55(2 \mathrm{H}, \mathrm{br} \mathrm{d}, J=\sim 7 \mathrm{~Hz}), 6.95 \sim 6.60(\mathrm{XH}$, unclear due to overlapping), $6.67(5 \mathrm{H}, \mathrm{s}, \mathrm{Cp})$, 6.43 ( 1 H ?, slightly br, d, $J=8 \mathrm{~Hz}$ ), 6.37 ( 1 H , slightly br, d, $J=8 \mathrm{~Hz}$ ), $5.86(5 \mathrm{H}, \mathrm{s}, \mathrm{Cp})$, 3.28 ( 3 H , slightly br s, OMe), 2.99 ( $3 \mathrm{H}, \mathrm{s}, \mathrm{OMe}$ ). Other methoxy signals: 3.27 ( $3 / 2 \mathrm{H}$ ), 3.17 ( $\mathbf{3} / 2 \mathrm{H}$ ). X-ray crystallography: see Appendix A-21.

## 59: $\boldsymbol{E}-\left\{\mathrm{C}_{28} \mathrm{H}_{22} \mathrm{O}_{4}\right\}(\mathrm{Ti})(\mathrm{AlEtCl})_{2}$

To a solution of $52(0.0087 \mathrm{~g}, 0.016 \mathrm{mmol})$ in 0.5 mL of toluene was added $\mathrm{Et}_{3} \mathrm{Al}$ ( $0.0037 \mathrm{~g}, 0.032 \mathrm{mmol}$ ) dissolved in 1 mL of toluene. The ruby-red color of the starting material immediately turned less reddish, more orange-brown in color. After overnight, the volatiles were removed in vacuo. In the process of removing the volatiles, some crystals were grown. The yield was $0.0109 \mathrm{~g}(96 \%)$. The 'H NMR spectrum showed a single clean compound. X-ray crystallography of the crystals revealed the structure of the product 59. ${ }^{1} \mathrm{H}$ NMR ( $360 \mathrm{MHz}, \mathrm{C}_{6} \mathrm{D}_{6}$ ): $\delta 7.09(2 \mathrm{H}$, slightly br d, $\sim 8 \mathrm{~Hz}$ ), $6.93(2 \mathrm{H}$, dd, J $=6.5 \sim 7, \sim 2.5 \mathrm{~Hz}), 6.86(2 \mathrm{H}, \mathrm{dd}, J=7.3,1.8 \mathrm{~Hz}), 6.72(2 \mathrm{H}, \mathrm{td}, J=8,1.8 \mathrm{~Hz}), 6.66 \sim 6.61$ ( $2 \mathrm{H}+2 \mathrm{H}+2 \mathrm{H}$, overlapping), $6.23(2 \mathrm{H}, \mathrm{dd}, J=\sim 7, \sim 2 \mathrm{~Hz}$ ), $3.96(6 \mathrm{H}, \mathrm{s}, \mathrm{OMe}), 1.43(6 \mathrm{H}, \mathrm{t}$, $\left.J=8 \mathrm{~Hz}, \mathrm{AlCH}_{2} \mathrm{CH}_{3}\right), 0.99\left(6 \mathrm{H}, \mathrm{t}, J=8 \mathrm{~Hz}, \mathrm{AlCH}_{2} \mathrm{CH}_{3}\right), 0.50\left(4 \mathrm{H}, \mathrm{m}, \mathrm{AlCH}_{4} \mathrm{H}_{\mathrm{R}} \mathrm{CH}_{3}\right)$,
$0.01\left(4 \mathrm{H}, \mathrm{m}, \mathrm{AlCH}_{3} \mathrm{H}_{\mathrm{l}} \mathrm{CH}_{3}\right)$. ${ }^{13} \mathrm{C}$ NMR ( $100 \mathrm{MHz}, \mathrm{C}_{6} \mathrm{D}_{6}$ ): 159.4, 158.1, 145.4, 137.4, 135.1, 133.9, 133.00, 132.97, 124.5, 123.7; one aromatic signal is not found; 69.3 (OMe), $20.6\left(\mathrm{AlCH}_{2} \mathrm{CH}_{3}\right), 20.0\left(\mathrm{Al}^{\prime} \mathrm{CH}_{2} \mathrm{CH}_{3}\right), 14.8\left(\mathrm{AlCH}_{2} \mathrm{CH}_{3}\right), 13.7\left(\mathrm{Al}^{\prime} \mathrm{CH}_{2} \mathrm{CH}_{3}\right) . \mathrm{X}$-ray crystallography: see Appendix A-21.

### 5.0. Introduction and Overview

The potential of selected metal derivatives described in the previous chapters to be ethene polymerization catalysts, upon activation, was examined, and the results are presented in this chapter. The titanium complexes derived from the preorganized aryloxy ligands are first evaluated and discussed (Section 5.1). Then magnesium-derived precatalysts, which were found to give high polymerization activity, are then discussed (Section 5.2).

Titanium complexes. As discussed in Chapter 2, some aryloxy-based titanium/zirconium complexes are known to give high activity in ethene polymerization. Accordingly, the titanium complexes prepared from the preorganized aryloxide-based ligands $E$ - and $Z$-bis(2-hydroxyphenyl)-bis(2-methoxyphenyl)ethene (3E/3Z), tetrakis(2-hydroxy-3-propylphenyl)ethene (7) and 2,7-bis(1,1-dimethylethyl)-9H-fluorene-1,8-diol (4) were evaluated for polymerization activity. Two of the most typical activation methods for Group 4 metal complexes ${ }^{1}$ were used to produce the cationic species that served as the actual catalysts. The first method is to activate the titanium halide complex with excess alkylaluminum reagents $\mathrm{R}_{3} \mathrm{Al}(\mathrm{R}=\mathrm{Me}$ or Et ) or M-MAO (modified methyl aluminoxane). ${ }^{2}$ The second method is to induce alkyl abstraction from an alkyltitanium precatalyst complex by an electrophilic boron reagent or by protonolysis by using a proton source with inert counterbase and counteranion. Among these trials, only the titanium complexes of the fluorene-diol ligand 4 showed promising levels of activity. Other titanium derivatives from 3E and 7, the tetraarylethene based ligands, failed to show comparable polymerization ability.

The magnesium effect. Verkerk observed high polymerization activity when a titanium complex was prepared in situ from the magnesium salt/complex of tetrakis(2hydroxyphenyl)ethene 2 and several simple chelating bisphenols upon mixing with $\mathrm{TiCl}_{4}{ }^{3}$ In contrast, the precatalysts similarly prepared from potassium salts of the same aryloxy ligands showed only poor activity. This phenomenon is termed the "magnesium effect," because the involvement of magnesium is crucial in giving high polymerization activity. We found a similar tendency for the magnesium salts of the above-mentioned ligands.

The magnesium effect, however, was not specific to the preorganized ligands, but was also observed for simpler magnesium phenoxides. The advantage of the preorganized ligand was manifest as a relatively narrower polydispersity of the product polymers and the robustness of the catalyst at higher temperature. The molecular weight of the polymer gained by the magnesium method is usually high, beyond the normal range for high temperature GPC analysis. High temperature experiments, as well as $\mathbf{H}_{2}$-incorporated experiments, were performed to lower the average molecular weight and obtain analyzable polyethene products.

In this research, we focused on the polymerization activity, using only ethene as a monomer. We did not focus on the polymerization of $\alpha$-olefins, ethene $/ \alpha$-olefin copolymerization, or control of polymer quality.

In the experimental section, preparation of the main-group metal salts/complexes and some titanium complexes, our analysis method for the composition of the magnesium salts, and detailed procedures for the polymerization reactions are described.

### 5.1. Titanium Precatalysts

The titanium complexes tested for ethene polymerization are listed in Figure 5.1. The synthesis and characterization of the titanium complexes from the tetraarylethenebased ligands 7 and 3E were described in Chapters 3 and 4. Because no discrete titanium complex was isolated for ligand 3 Z , only in situ prepared $\mathrm{TiCl}_{4}$ adducts of the magnesium salt were used. In situ preparation was also used for 30a and 30, the titanium chloride derivatives of ligand 7. Complexes 71 and 72, titanium derivatives of the fluorene-diol ligand 4, were prepared from the sodium and magnesium salts in toluene (the coordinated THF in 72 was carried through from the starting magnesium salt). Wuest et al. reported the preparation and crystal structure of the THF-free complex 71 in $1998 .{ }^{4}$ The crystal structure of the THF-coordinated analogue 72 was obtained during our research (see Appendix A-22). This structure is one of several results in this research that confirm the transfer of coordinated THF from Mg to Ti atom upon the reaction of a magnesium salt and $\mathrm{TiX}_{4}$.

Figure 5.1. Structures of the titanium complexes that appear in Table 5.1.

Overall, the titanium complexes from the tetraarylethene-based ligands 7 and $\mathbf{3 E}$ showed poor ethene-polymerization activity. The titanium derivatives of the fluorene-diol ligand 4, however, displayed promising polymerization activity. Table $\mathbf{5 . 1}$ summarizes the polymerization activity by the above-mentioned titanium complexes upon activation by co-catalysts. The data presented in entry 21 are from a control run, using $\mathrm{TiCl}_{4}$ alone, without any ligand support.

General conditions. Solvent: toluene, 5 to 8 mL ; catalyst amount: $1 \sim 8 \times 10^{-6} \mathrm{~mol}$; ethene pressure: $30 \mathrm{psig}(\sim 3 \mathrm{~atm})$; polymerization time : $5 \sim 30 \mathrm{~min}$.

[^16]Chapter 5 5.1. Ti Precatalysts page 217
i) Titanium complexes of ligand 7. As shown in Table 5.1, entries $1-15$, the titanium complexes derived from tetrakis(2-hydroxy-3-propylphenyl)ethene (7) exhibited only low ethene polymerization activity. The activity was typically below that of the control run ( $22 \mathrm{~kg} \mathrm{PE} \cdot \mathrm{hr}^{-1} \cdot \mathrm{~mol} \mathrm{Ti}^{-1} \cdot \mathrm{~atm}^{-1}$ ). Obviously, the preorganized tetraaryloxide platform does not provide a good catalytic titanium site from the geminal or vicinal "up/down" complexes $30 \mathrm{a}, 31,34$ and 35 , or from the $\mathrm{Ti} / \mathrm{Mg}$ and $\mathrm{Ti} / \mathrm{Al}$ complexes 45 and 46.

The first four complexes (entries 1-13) are in the "up/down" configurations, in which each bidentate chelating unit presumably acts individually. Unlike the bisphenol ligands known to form Ti or Zr complexes that show good polymerization activity (Chapter 2), the pairwise formation of titanium centers in these complexes probably do not provide enough steric protection to form effective catalysts. Replacing one Cl group on each " $\mathrm{TiCl}_{2}$ " fragment in complex 30 with a Cp ligand (34), however, did not improve the situation.

Entries 3-4, in which complexes $\mathbf{3 0 a}$ and 30 were prepared in situ from magnesium complex 25 or sodium salt 40 because both were difficult to isolate, showed relatively higher activities than those of the isolated titanium chloride complexes ( $\mathbf{3 1}$ and 34). These activities, however, are suspected to come from the involvement of the byproduct inorganic salts, $\mathrm{MgCl}_{2}(\text { (thf })_{\mathrm{n}}$ ( $\mathrm{n}=0$ or 1 ) for the former and NaCl for the latter (Scheme 5.1). The involvement of $\mathrm{MgCl}_{2}(\text { thf })_{\mathrm{n}}$ will be discussed in more detail later as the "magnesium effect."

The di-" $\mathrm{TiBn}_{2}$ " complex 35 was expected to form a discrete $\left[\mathrm{Ti}_{2}\right]^{+}$complex 36 (Scheme 5.2) upon reaction with $B\left(C_{6} F_{5}\right)_{3}$, which polymerized THF (see Section 3.1.2.F). However, low to no ethene polymerization was observed when using any of the boron or borate co-catalysts (entries 8-13). Only the conditions closest to those under which 36 was synthesized (entry 9) gave activity comparable to the control run (entry 21). It may be noted that despite the low activity, this was the only experiment that showed any polymerization activity without involvement of inorganic salts, among all titanium complexes of the tetraarylethene-based ligands 7, 3E, and 3Z.

25

30n

Scheme 5.1. In situ formation of 30a and $\mathbf{3 0}$ accompanied by the formation of inorganic salts.

Scheme 5.2. Reaction between 35 and $B\left(C_{6} F_{5}\right)_{3}$ and the proposed structure of 36 .

The two hetero-polymetallic complexes, 45 and 46, did not provide good catalysts, although such hetero-polymetallic species were expected to serve as surface models for heterogeneous Ziegler-Natta catalysts. These particular complexes do not provide suitable environments for catalysis: the titanium atom is surrounded by four oxygen donors in both cases, making three ionic and one dative bonds, probably providing too much electron density to the titanium atom. The pseudo-octahedral
coordination geometry is also apparently not suitable for polymerization, because this geometry does not allow for the creation of two adjacent vacant coordination sites, which are normally required for olefin polymerization. ${ }^{5}$
ii) Titanium complexes of ligand 3E. The mononuclear " $\mathrm{TiCl}_{2}$ " complex 52, in which one of the two methoxy groups are coordinated to the titanium atom to bring some level of steric and electronic protection to the metal, also does not give measurable polymerization (entries 16-17). This inertness, however, is well explained by the reactivity of this complex toward $\mathrm{Et}_{3} \mathrm{Al}$, as discussed in Chapter 4, Section 4.3.A. Addition of two equivalents of $\mathrm{Et}_{3} \mathrm{Al}$ led to the reduction of the $\mathrm{Ti}(\mathrm{IV})$ to $\mathrm{Ti}(\mathrm{II})$, resulting in the formation of complex 59 (Scheme 5.3). Formation of a cationic titanium center cannot be expected from this species, even in the presence of excess aluminum cocatalysts. Constructing hetero-polymetallic species was intended to be a potentially new way to introduce steric protection to the titanium center, but with the formation of 59, the aluminum coordination promotes the reduction of the titanium (see Section 4.3.A). Complex 59 also has a pseudo-octahedral geometry, which again may not be suitable for allowing for the creation of two adjacent vacant sites. The coordination of the olefin in the ligand to the titanium draws the metal "down" into an unsuitable geometry for olefin polymerization. The use of larger zirconium metal may avoid such interaction with the double bond and form a more favorable geometry.

59

Scheme 5.3. Formation of $\mathbf{5 9}$ from 52 and two equivalents of $\mathrm{Et}_{3} \mathrm{Al}$.

The $\mathrm{TiBn}_{2}$ complex 55 (Scheme 5.4) was not tested for ethene polymerization because the isolation of 55 in analytically pure form was not successful. Upon alkyl abstraction, however, both methoxy groups will presumably be strongly coordinated to the cationic titanium center, forming a pseudo-octahedral coordination geometry
(counting the olefin double bond as one ligand), again unsuitable for forming two adjacent vacant sites (Scheme 5.4).
 benzyl
abstraction

Scheme 5.4. A proposed 'dead end' cationic titanium from 55.

Although ligand 3E did not show a suitable environment for polymerization as titanium complexes, use of other metals with larger radii may result in forming a more preferable geometry in which the metal may lie out of the $\mathrm{O}_{4}$ plane. ${ }^{6}$
iii) Titanium derivatives of ligand 3Z. Only by in situ preparation from the magnesium salt of 3 Z and two equivalents of $\mathrm{TiCl}_{4}$ could polymerization be evaluated because discrete titanium complexes could not be prepared cleanly. The activity observed was low, on the level of the control run (entry 18). Still, the activity was relatively higher than that of most isolated titanium complexes that show no measurable activity. This activity is also presumably caused by the presence of the inorganic magnesium byproduct.
iv) Titanium derivatives of the 1,8 -fluorene-diol 4. The titanium complexes derived from the fluorene-diol ligand 4, dinuclear complexes 71 and 72, showed considerably higher activity (entries 19-20) than the catalysts derived from the tetraarylethene-based ligands. These activity values fall within the accepted criteria of "high" activity, according to a review of non-metallocene homogeneous catalysts. ${ }^{7}$

The THF-free complex 71 showed higher activity than THF-solvated 72. Without repetition of the experiments, ${ }^{3}$ it is difficult to say that the difference ( 226 vs .156 kg

[^17]Chapter 5 5.1. Ti Precatalysts page 221
$\mathrm{PE} \cdot \mathrm{hr}{ }^{-1} \cdot \mathrm{~mol} \mathrm{Ti}^{-1} \cdot \mathrm{~atm}^{-1}$ ) is statistically significant; for roughly $\mathbf{1 0}$ to $20 \%$ error is expected in typical polymerization procedures. Nevertheless, this observation is reasonable because THF is expected to deactivate a cationic titanium center. With excess co-catalyst, however, the effects of a small amount of THF may not be significant.

When the precatalyst was prepared in situ from the magnesium salt of 4, even higher activity was obtained than from the preformed titanium complexes. The highest value obtained by this method was $821 \mathrm{~kg} \mathrm{PE} \cdot h r^{-1} \cdot \mathrm{~mol} \mathrm{Ti}^{-1} \cdot \mathrm{~atm}^{-1}$, the record performance for all of the small-scale experiments in this research. This is a good example of the "magnesium effect." Table 5.2 summarizes the comparisons of different precatalysts (either preformed complexes or in situ-prepared) derived from the fluorene-diol ligand 4. The first two entries ( $l$ and 2 ) are the same as entries 19 and 20 of Table 5.1. This table also serves as an appropriate introduction to the general discussion of the magnesium effect, Section 5.2.

### 5.2. Magnesium Effect

### 5.2.A. Derivatives of the Fluorene-diol Ligand 4

As shown in Table 5.2, the in situ preparation of a titanium precatalyst from the magnesium salt of 4 (labeled 74, entries 4-13) gives considerably higher activity than does the use of discrete titanium complex 71 or 72 or the use of precatalysts prepared in situ from the corresponding sodium salt.

The magnesium salt 74 was prepared by mixing ligand 4 and two equivalents of $\mathrm{CH}_{3} \mathrm{MgCl}$ in THF overnight. Although crystallization of the THF-soluble product from toluene failed to yield crystals suitable for X-ray analysis, the composition of the resulting substance was calculated as $[4-2 \mathrm{H}] \cdot \mathrm{Mg}_{2.5}{ }^{\circ} \mathrm{Cl}_{3.0}{ }^{\circ}(\mathrm{thf})_{2.8}$ based on the elemental analysis (see Section 5.4.B). From the composition, the salt is tentatively assigned to be a di- $\mathrm{MgCl}($ thf) salt, as drawn in Table 5.2 (for entries 4-13), accompanied by approximately 0.5 equivalent of $\mathrm{MgCl}_{2}(\mathrm{thf})$.

Table 5.2. The different conditions to produce a catalyst from the metal derivatives of 4. Entries 1 and 2 are the same as entries 19 and 20 of Table 5.1).

| 12 |  | $+2 \mathrm{TiCl}_{4}(1 \mathrm{~min})$ | M-MAO 200 | 606 |
| 13 |  | $+2 \mathrm{TiCl}_{4}(28 \mathrm{~min})$ | M-MAO 200 | 51 |

Entries 7-9 and 12-13 are the results obtained from the precatalyst prepared in situ from the magnesium salt 74 and two equivalents of $\mathrm{TiCl}_{4}$ after a relatively short reaction time ("mixing time"), up to one hour. After prolonged mixing (such as several hours or

Chapter 5 5.2. The Magnesium Effect page 223
complex 72 as a precatalyst, because 72 was prepared in exactly this way. The in situ preparation, however, is accompanied by an insoluble byproduct $\mathrm{MgCl}_{2}$, which we assume would self-aggregate and precipitate out of the system after a long enough mixing time, remaining innocent in the polymerization reaction. However, $\mathrm{MgCl}_{2}$ may not be completely excluded from the system within a short mixing time, somehow incorporated into the newly formed titanium complex. We therefore suspect that the considerably higher polymerization activity obtained from the short-time mixture of the magnesium salt and $\mathrm{TiCl}_{4}$ arises from the involvement of magnesium chloride in the precatalyst.

This in situ preparation of the Ti precatalyst from a main-group metal salt was only effective with the magnesium salt. The use of sodium salt of ligand 4 (labeled 73, entry 3) resulted in an activity as low as that obtained from the control experiment lacking any ligand (entry 21, Table 5.1). This result indicates the superiority of the effect of magnesium over that of sodium in giving high polymerization activity. This comparison may not be totally fair, however, because only one set of conditions was evaluated for the sodium salt. The low activity of entry 3 may be due to the formation of a "coilapsed" final product as shown in Scheme 5.5. We have not, however, prepared and isolated such dimeric species to confirm the polymerization inertness or activity.

Scheme 5.5. Proposed structure of precatalyst produced in entry 3: the $1: 1$ adduct of $\mathrm{TiCl}_{4}$ and the sodium salt of ligand 4.

Nonetheless, the analogous $1: 1$ adduct of the magnesium salt and $\mathrm{TiCl}_{4}$, formed in situ (entries 4-6) gave considerably higher activity than that obtained from the sodium salt, supporting the superior effect of the magnesium involvement.

The magnesium effect was found to be considerably sensitive to the mixing time. The best polymerization activity was obtained from mixing times ranging from 1 minute to 1 hour, and typically a decrease in activity was observed after longer mixing time.

Chapter 5 5.2. The Magnesium Effect page 224

Interestingly, the optimal mixing time was greatly affected by the co-catalyst. With $\mathrm{Me}_{3} \mathrm{Al}$, the best activity was obtained after around one hour mixing time, both with one or two equivalents of $\mathrm{TiCl}_{4}$ per magnesium salt, while a mixing time as short as one minute gave the highest activity when the co-catalyst was M-MAO.

Similar magnesium effects were observed with other phenoxide and polyaryloxide ligand systems. In the next section, results from magnesium, sodium and aluminum salts of several other ligands systems are discussed in detail.

### 5.2.B. Generalization of the "Magnesium Effect"

The graphs and tables on the following several pages present the results of the polymerization activity obtained by in situ preparation of precatalyst complexes from salts of the ligand systems shown in Figure 5.2: the tetraarylethene-based ligands 7, 3E, and 3 Z as preorganized systems; along with phenol, 3,3'-dimethyl-4,4'-biphenol, and hydroquinone. The simpler phenoxide ligand systems provide a control for comparison with the preorganized systems. The non-chelating diols were chosen as a supplemental control template, for comparison with the magnesium effect in various chelating diols as studied by Verkerk. ${ }^{3}$

Chapter 5 5.2. The Magnesium Effect page 231

The dependence of the catalyst activity on mixing time was carefully examined for each system to record optimum performance and is summarized in graphs of activity vs. mixing time. The complete data on which the graphs are based are presented in the Experimental section (5.4.E). Results from sodium and aluminum salts were less rigorously evaluated and are given in table form.

Consistent reaction conditions were used: the standard small-scale procedure (detailed in Section 5.4.C) was used throughout, in toluene medium and under 30 psig of ethene pressure. Activation of the in situ-prepared titanium precatalyst was by $\mathrm{Me}_{3} \mathrm{Al}$ ( 100 equiv. $\mathrm{Al} / \mathrm{Ti}$ ), $\mathrm{Et}_{3} \mathrm{Al}$ ( 100 equiv. $\mathrm{Al} / \mathrm{Ti}$ ), or M-MAO (200 equiv. $\mathrm{Al} / \mathrm{Ti}$ ). Different ratios of [ligand : $\mathrm{TiCl}_{4}$ ] were evaluated for each system. Because of the small scale, an internal error of $10-20 \%$ is reasonably expected. Some salts displayed lower reproducibility than did others.

The formula weight and composition of the magnesium salts were calculated from C/H elemental analysis data (detailed in Section 5.4.B). The formula of the sodium salts was assumed to be "ArONa" when the salt was obtained from the reaction between ArOH and NaH , except for the sodium salt 40 , derived from tetrakis(2-hydroxy-3propylphenyl)ethene 7, which was crystallized and analyzed by C/H elemental analysis.

A summary of the noteworthy trends and results determined in this series of experiments appears below.
i) Typical activity. The polymerization activities obtained by the precatalysts prepared in situ from the magnesium salts and $\mathrm{TiCl}_{4}$ (presented in Charts 1-6) show that the magnesium effect is universal to all phenoxides, preorganized or simple. The optimal activity recorded for each magnesium salt was $400-600 \mathrm{~kg} \mathrm{PE} \cdot \mathrm{hr}^{-1} \cdot \mathrm{~mol} \mathrm{Ti}^{-1} \cdot \mathrm{~atm}^{-1}$, with few exceptions. Sodium salts, as well as aluminum complexes in some cases, were notably ineffective, similar to the control run level presented in Table 5.1, entry 21 ( -20 kg PE $\cdot \mathrm{hr}^{-1} \cdot \mathrm{~mol} \mathrm{Ti}^{-1} \cdot \mathrm{~atm}^{-1}$ ) or only slightly higher.
ii) Mixing time dependence. The optimal mixing time clearly varies with the ligand system used. The highest polymerization activities were often obtained after mixing times as short as 1~5 minutes for many precatalysts in the 7 series (see, e.g., Figure 5.3-c),
while a prolonged range of "good" mixing times was observed using simple phenol (Figure 5.5).

The best mixing time is also a function of titanium stoichiometry and the cocatalyst used. For many cases, however, the graphs show a maximum, and then the activity drops after a longer mixing time. Applying infinite mixing time is presumed to be equivalent to the use of titanium-only complexes, as for ligand 7 in the titanium complex series (Table 5.1, entries 3-4). Nevertheless, the diminished activity after a prolonged period of mixing time is still higher compared to that obtained from the use of titanium complexes only, which do not show any measurable activity, and is considered to come from the byproduct $\mathrm{MgCl}_{2}(\mathrm{thf})_{\mathrm{n}}$ combined with the titanium complexes.
iii) Reproducibility. The reproducibility of the magnesium method seems to depend mainly on the solubility of the starting aryloxymagnesium salt in toluene. Poor reproducibility manifests itself as different activities at a similar mixing time. One example is shown in Figure 5.4-b (Chart 2), at approximately 30 minutes of mixing time (in the series of two equivalents of $\mathrm{TiCl}_{4}$ per ligand in salt 75). Activity of 413 kg PEehr ${ }^{-1} \cdot \mathrm{~mol} \mathrm{Ti}^{-1} \cdot \mathrm{~atm}^{-1}$ was observed at one time, but only $164 \mathrm{~kg} \mathrm{PE} \cdot \mathrm{hr}^{-1} \cdot \mathrm{~mol} \mathrm{Ti}^{-1} \cdot \mathrm{~atm}^{-1}$ was observed in a different run. The toluene solubility of the magnesium salt in this series was poor, compared to that of the reasonably reproducible cases, such as both ligand 7 and phenol-derived catalysts.

The size of the particles/crystals of the magnesium salts also reflects on the reproducibility. The size mostly impacts the time of maximum activity: the best mixing times occur earlier using finer particles of the magnesium salt. For example, the best mixing time for crystals of magnesium complex 25 (from ligand 7) with two equivalents of $\mathrm{TiCl}_{4}$, activated by $\mathrm{Me}_{3} \mathrm{Al}$ (Figure 5.3-a), was approximately 20 minutes in this series, while in a separate series of experiments using finer crystals, the best mixing time optimized as early as $1-3$ minutes. The larger surface area of finer particles presumably increases the rate of dissolution in toluene, and in turn, the rate of reaction with $\mathrm{TiCl}_{4}$.
iv) Inert magnesium derivatives. Although the magnesium effect is typically observed across various aryloxymagnesium salts, consistently poor activity in certain cases was observed at any mixing time. The magnesium salt 76, derived from ligand $3 \mathbf{Z}$, in particular, was inert over wide range of mixing times, when either one or two equivalents of $\mathrm{TiCl}_{4}$ per ligand were used (Table 5.5). The initial reaction between the

Chapter 5 5.2. The Magnesium Effect page 233
salt and $\mathrm{TiCl}_{4}$ appeared to be unusually slow: the color of the mixture did not turn red clearly during the mixing time periods detailed in Table 5.5, while the corresponding reactions of the $E$ - analogue ( $\mathbf{7 5}$ from 3 E ) immediately turned red. The very poor solubility of the magnesium salt of ligand $\mathbf{3 Z}$ is possibly to blame, but if this is alone responsible, at least some correlation of activity and mixing time would be expected.

Another consistently low activity case is the [Ligand : $\mathbf{T i}=1: 1$ ] stoichiometry of the magnesium salt 25 derived from ligand 7 as shown in Figure 5.3-a and -b (Chart 1). It is plausible that the reaction at this stoichiometry resulted in the formation of the collapsed "sandwich" type complex 32 (see Chapter 3, Section 3.1.2.D), which is an unsuitable precatalyst.
v) Co-catalysts. Overall, both $\mathrm{Me}_{3} \mathrm{Al}$ and M -MAO functioned as co-catalysts, giving comparable polymerization activity. The fact that $\mathrm{Me}_{3} \mathrm{Al}$ is as effective as M-MAO suggests that the actual catalyst is functionally more similar to classic heterogeneous Ziegler-Natta catalysts than to metallocene-type homogeneous catalysts. The activity level, up to $600 \mathrm{~kg} \mathrm{PE}_{\mathrm{ehr}}{ }^{-1} \cdot \mathrm{~mol} \mathrm{Ti}^{-1} \cdot \mathrm{~atm}^{-1}$ (in large-scale experiments, the highest activity was over $1,000 \mathrm{~kg} \mathrm{PE} \cdot \mathrm{hr}{ }^{-1} \cdot \mathrm{~mol} \mathrm{Ti}^{-1} \cdot \mathrm{~atm}^{-1}$ ), is also similar to the activities reported for " $\mathrm{MgCl}_{2}$-supported $\mathrm{TiCl}_{4}$ " type heterogeneous catalysts. ${ }^{8}$

Meanwhile, for other systems, one of the co-catalysts $\left(\mathrm{Me}_{3} \mathrm{Al}\right.$ or M-MAO) gave consistently superior activities. For example, the use of $\mathrm{Me}_{3} \mathrm{Al}$ provides better activity for the magnesium salt 77 derived from simple phenol at [Ligand : $\mathrm{Ti}=1: 0.5$ ] (Figure 5.5a and -b, Chart 4), while M-MAO was clearly superior for the magnesium salt 78 derived from 3,3'-dimethyl-4,4'-biphenol at [Ligand : $\mathrm{Ti}=1: 2$ ] (Figure 5.6-a and -b, Chart 5). The co-catalyst also affected the optimal mixing time and the reproducibility. These observations suggest that the co-catalyst is somehow involved in the actual catalyst structure, affecting the solubility and aggregation tendency, if not the actual catalytic center.
vi) Molecular weight of the polyethene. The polymer products obtained from the magnesium precatalysts have a very high average molecular weight. Analysis by standard high-temperature GPC (gel permeation chromatography) was not possible because the polymer would not dissolve in $1,2,4$-trichlorobenzene at temperatures up to $130^{\circ} \mathrm{C}$. High crystallinity of the polymer produced is also suggested by this observation. Modified
polymerization procedures were therefore adopted to lower the molecular weight of the polyethene for analysis of the polydispersity (vide infra).

### 5.2.C. Possible Origins of the Magnesium Effect

Obviously, the direct involvement of magnesium in the catalytic active site is essential to optimize the observed polymerization activity for titanium precatalysts prepared in situ from magnesium salts. We suspect that the magnesium dichloride that is formally produced upon the reaction of the aryloxymagnesium salts with $\mathrm{TiCl}_{4}$ is intimately involved in the actual catalysts. Scheme $\mathbf{5 . 6}$ provides a proposed scenario for the reaction between magnesium aryloxide, represented by salt 77 derived from simple phenol, and one equivalent of $\mathrm{TiCl}_{4}$.

Scheme 5.6. Suggested $\mathrm{MgCl}_{2}$-incorporated phenoxytitanium chloride precatalysts produced from the reaction of 77 with $\mathrm{TiCl}_{4}$.

The $\mathrm{MgCl}_{2}$ is considered to be bridged via chlorides and phenolato-oxygens to the newly formed (ArO) $\mathrm{TiCl}_{4 \mathrm{x}}(\mathrm{x}=1$ or 2 ) right after the kinetic transmetallation.

Activation of this species by a co-catalyst then produces an active catalyst that still retains bridging magnesium. However, after a long mixing time, the dissociation of magnesium dichloride from the aryloxytitanium unit proceeds. $\mathrm{MgCl}_{2}$, as a THF-solvate, subsequently self-aggregates and precipitates out of the system, driving the thermodynamics and preventing re-association to the aryloxytitanium unit. In the scheme, the dissociation of titanium and magnesium units is depicted as being promoted by THFtransfer from magnesium to titanium, although it is not applicable for non-THF magnesium salts. The precipitated $\mathrm{MgCl}_{2}$ may still be capable of interacting with limited amount of titanium complexes on its surface to create some effective precatalysts, because the precatalyst mixture after long enough mixing time still give the polymerization activity higher than that of titanium-only complexes with no $\mathbf{M g C l}_{2}$ present.

The rate of this second step is expected to vary among the different aryloxy ligands. The simple phenoxide retained good activity over an exceptionally long mixing time range. Most other cases, however, showed high polymerization activity only for a short time period, between one and sixty minutes. The dissociation of magnesium chloride from the effective precatalyst stage is, apparently, quite fast for most aryloxy systems.

In some ways, these precatalysts prepared by mixing the magnesium salts and $\mathrm{TiCl}_{4}$ are a microscale version of $\mathrm{MgCl}_{2}$-supported $\mathrm{TiCl}_{4}$ heterogeneous Ziegler-Natta catalysts, in which $\mathrm{TiCl}_{4}$ is typically supported on fine particles of anhydrous $\mathrm{MgCl}_{2}$, or $\mathrm{Ti} / \mathrm{Mg}$ precatalysts deposited on silica supports. ${ }^{9}$ Small cluster particles or possibly molecular-level $\mathrm{MgCl}_{2}$ presumably exist for a short time period and serves to "support" the partly aryloxylated titanium chlorides. This system, therefore, may resemble the silica-supported $\mathrm{Ti} / \mathrm{Mg}$ chloride precatalysts, which are widely used in industry, with the aryloxide ligand replacing the silica structure.

### 5.2.D. Isolation of Magnesium-incorporated Titanium Precatalysts

Because the magnesium salt $77\left[\mathrm{PhOMgCl}(\text { (thf })_{2}\right]$ derived from phenol showed a minimal correlation of activity and mixing time, in contrast to most other aryloxymagnesium salts, the isolation of the magnesium-incorporated precatalysts was possible. The adducts of the magnesium salt 77 and both 0.5 and 1 equivalent of $\mathrm{TiCl}_{4}$ per ligand were prepared in hexanes ( 0.5 equiv.) or toluene ( 1 equiv.), and the products

Chapter 5 5.2. The Magnesium Effect page 236
were isolated as amorphous precipitates (labeled 84 and 85 , respectively). These precipitates showed ethene polymerization activities of 315 and $277 \mathrm{~kg} \mathrm{PE} \cdot \mathrm{hr}^{-1} \cdot \mathrm{~mol}$ $\mathrm{Ti}^{-1} \cdot \mathrm{~atm}^{-1}$, respectively, when activated by ca. 300 equivalents of $\mathrm{Et}_{3} \mathrm{Al}$. Attempts to crystallize these $\mathrm{Mg} / \mathrm{Ti}$ adducts from non-coordinating hydrocarbon medium were, unfortunately, not successful.

For comparison, the [77: $\mathrm{TiCl}_{4}=1: 2$ ] adduct (labeled 86) was prepared in hexanes by the same procedure. No in situ preparation of precatalysts in this ratio was evaluated to obtain the mixing-time correlation. This adduct showed an activity of only $22 \mathrm{~kg} \mathrm{PE} \cdot \mathrm{hr}^{-1} \cdot \mathrm{~mol} \mathrm{Ti}^{-1} \cdot \mathrm{~atm}^{-1}$. Two equivalents of titanium per aryloxy moiety are apparently not appropriate to produce effective catalysts.

### 5.2.E. Effects of halide and solvated THF/ether

To specify which part of the $\mathrm{MgCl}_{2}(\text { thf })_{n}$ was related to the origin of the high polymerization activity, the effects of halide and the solvate ligands (THF or $\mathrm{Et}_{2} \mathrm{O}$ ) were evaluated by comparing the chloro and bromomagnesium salts, and the THF and $\mathrm{Et}_{2} \mathrm{O}$ solvates. The halide effects were also evaluated by using both $\mathrm{TiCl}_{4}$ and $\mathrm{TiBr}_{4}$. The two ligand systems used in this study were the ortho-propylated ligand 7 and phenol.
i) Halide influences. The aryloxymagnesium chlorides and bromides derived from ligand 7 and phenol (Table 5.8), all THF-solvated, were compared for polymerization activity by the preparation of precatalysts with $\mathrm{TiCl}_{4}$ or $\mathrm{TiBr}_{4}$. The composition and/or structure of the MgCl and MgBr salts are identical for both ligands, a factor that enabled a fair comparison. For both ligands, the stoichiometry of titanium was adjusted so one equivalent of titanium was provided per two aryloxide moieties. The results are summarized in Figures 5.8 (for the salts derived from ligand 7) and 5.9 (for the salts derived from phenol) as a function of the mixing time. The co-catalyst is $\mathrm{Me}_{3} \mathrm{Al}(100$ equiv. $\mathrm{Al} / \mathrm{Ti}$ ) for all cases.

Table 5.8. Composition of the magnesium salts evaluated for the influence of halides on the magnesium effect.

|  | Salt of ligand 7 | Salt of phenol |
| :---: | :---: | :---: |
| $\mathrm{Mg} / \mathrm{Cl} /$ (thf) salt | $\begin{gathered} {[7-4 \mathrm{H}] \mathrm{Mg}_{3} \mathrm{Cl}_{2}(\mathrm{thf})_{3}} \\ (25) \end{gathered}$ | $\mathrm{C}_{6} \mathrm{H}_{5} \mathrm{OMgCl}(\mathrm{thf})_{2}$ <br> (77) |
| $\mathbf{M g / B r} /($ thf) salt | $[7-4 \mathrm{H}] \mathrm{Mg}_{3} \mathrm{Br}_{2}(\mathrm{thf})_{3}$ <br> (26) | $\begin{gathered} \mathrm{C}_{6} \mathrm{H}_{5} \mathrm{OMgBr}(\mathrm{thf})_{2} \\ (82) \end{gathered}$ |

Different halides in the starting magnesium salts had a minimal effect on the polymerization activity and the mixing-time dependence when $\mathrm{TiBr}_{4}$ was used as a titanium source (Figure 5.8-b and 5.9-b). With $\mathrm{TiCl}_{4}$, however, the behavior of MgCl and MgBr salts was quite different. The MgBr salt of ligand 7 gave better activities with $\mathrm{TiCl}_{4}$ (Figure $5.8-\mathrm{a}$ ), while the MgBr salt of phenol formed an inefficient precatalyst (Figure 5.9-a).

To explain this observation, one hypothesis is that the aryloxytitanium halide (ArO)TiX ${ }_{2}(\text { thf })_{n}$ can be active only when incorporated with a certain $\mathrm{MgXX}^{\prime}$ salt. The trends shown in Figures 5.8 and 5.9 suggest that to be an effective catalyst, (ArO) $\mathrm{TiCl}_{2}(\mathrm{thf})_{\mathrm{n}}$ must be combined with $\mathrm{MgCl}_{2}$, not $\mathrm{MgBr}_{2}$ or MgClBr , while (ArO) $\mathrm{TiBr}_{2}\left(\mathrm{thf}_{\mathrm{n}}\right.$ can be an active catalyst with either $\mathrm{MgBr}_{2}$ or $\mathbf{M g B r C l}$. Schemes $\mathbf{5 . 7}$ and 5.8 provide a summary of the aryloxytitanium halides and magnesium halides resulting from the precatalyst-preparation reactions. In these schemes, the combination of the MgBr salt of phenol and $\mathrm{TiCl}_{4}$ (Scheme $5.8-\mathrm{c}$ ), which gave poor polymerization activities, does not provide a magnesium salt with the halide matching those of the $(\mathrm{ArO})_{2} \mathrm{TiCl}_{2}$. The bromide ion, larger in size than chloride, may interfere with the interaction between magnesium and titanium via $\mu$-halide or $\mu$-oxo bridges. With the $(\mathrm{ArO})_{2} \mathrm{TiBr}_{2}$, on the other hand, the bromide on the magnesium salt may be able to provide the necessary bridging ligand (Scheme 5.7-b).

Although how the different halides bridge or interfere with the structure of the precatalysts is not clear, the influences of mixed-halide systems are another implication that titanium and magnesium interact via $\mu$-halide bridges in the active catalysts.

Figure 5.8. Ethene polymerization activity by the precatalysts prepared in situ from $\mathrm{Mg} / \mathrm{Cl}$ (thf) salt (25) and $\mathrm{Mg} / \mathrm{Br} /($ thf $)$ salt (26), derived from ligand 7, with 2 equiv. of $\mathrm{TiX}_{4}$. Co-catalyst: $\mathrm{Me}_{3} \mathrm{Al}(100 \mathrm{Al} / \mathrm{Ti})$.

Figure 5.9. Ethene polymerization activity by the precatalysts prepared in situ from $\mathrm{Mg} / \mathrm{Cl} /($ thf) salt (77) and $\mathrm{Mg} / \mathrm{Br} /($ thf $)$ salt (82) of phenol with 0.5 equiv. of $\mathrm{TiX}_{4}$. Co-catalyst: $\mathrm{Me}_{3} \mathrm{Al}(100 \mathrm{Al} / \mathrm{Ti})$.

Chapter 5 5.2. The Magnesium Effect page 240
ii) Coordination Solvent Influences. The comparison of THF and $\mathrm{Et}_{2} \mathrm{O}$ solvates was possible using ligand system 7 because a matching pair of magnesium salts, [7$4 \mathrm{H}] \mathrm{Mg}_{3} \mathrm{Cl}_{2}(\mathrm{thf})_{3}(25)$ and $[7-4 \mathrm{H}] \mathrm{Mg}_{3} \mathrm{Cl}_{2}\left(\mathrm{OEt}_{2}\right)_{3}(27)$, was obtained (Table 5.9). For the simple phenol system, however, a desirable match " $\mathrm{PhOMgCl}\left(\mathrm{OEt}_{2}\right)_{2}$ " for salt 77 $\left[\mathrm{PhOMgCl}(t h f)_{2}\right]$ was not obtained from the reaction of PhOH with one equivalent of BnMgCl in $\mathrm{Et}_{2} \mathrm{O}$. Instead, the product of this reaction had the composition of $\mathrm{PhO} \cdot \mathrm{Mg}_{0.6}{ }^{\circ} \mathrm{Cl}_{0.2} \cdot\left(\mathrm{OEt}_{2}\right)_{0.1}(83)$ This formula suggests a mixture of $(\mathrm{PhO})_{2} \mathrm{Mg}$ and 0.1 equiv. of $\mathrm{MgCl}_{2}\left(\mathrm{OEt}_{2}\right)$. Approximately 0.9 equiv. of $\mathrm{MgCl}_{2}\left(\mathrm{OEt}_{2}\right)$ was presumably removed from the product during washing with diethyl ether. Nevertheless, this salt 83 serves as an example of a magnesium salt with no solvation.

Table 5.9. Composition of the magnesium salts evaluated for the influence of solvating molecules on the magnesium effect.

|  | Salt of ligand 7 | Salt of phenol |
| :---: | :---: | :---: |
| $\mathrm{Mg} / \mathrm{Cl} /$ (thf) salt | $\begin{gathered} {[7-4 \mathrm{H}] \mathrm{Mg}_{3} \mathrm{Cl}_{2}(\mathbf{t h f})_{3}} \\ (25) \end{gathered}$ | $\mathrm{C}_{6} \mathrm{H}_{5} \mathrm{OMgCl}(\text { thf })_{2}$ <br> (77) |
| $\mathbf{M g} / \mathrm{Cl} /\left(\mathrm{OEt}_{2}\right)$ salt | $[7-4 \mathrm{H}] \mathrm{Mg}_{3} \mathrm{Cl}_{2}\left(\mathrm{OEt}_{2}\right)_{3}$ <br> (27) | $\mathrm{C}_{6} \mathrm{H}_{5} \mathrm{OMg}_{0.6} \mathrm{Cl}_{0.2}\left(\mathrm{OEt}_{2}\right)_{0.1}$ <br> (83) |

Figure 5.10 provides the comparison of magnesium salts 25 and 27 in the catalysts derived from two equivalents of $\mathrm{TiX}_{4}$. The data of $\mathbf{2 5}$ are the same as those used in Figure 5.8.

It is notable that the ether-solvated salt 27 retained a high level of activity over a prolonged mixing time, compared to that of the THF-solvate 25 , with both $\mathrm{TiCl}_{4}$ and $\mathrm{TiBr}_{4}$. Having $\mathrm{Et}_{2} \mathrm{O}$ as a solvate, instead of THF, presumably slows the dissociation of the $\mathrm{MgX}_{2}$ (solv) $\mathbf{n}^{\text {moiety }}$ from the $\mathrm{Mg}-\mathrm{Ti}$ incorporated precatalyst compared to the more basic THF. With less efficient coordination by less basic $\mathrm{Et}_{2} \mathrm{O}$, the $\mathbf{M g X}_{\mathbf{2}}$ unit is presumably more strongly coordinated by the $\mu$-heteroatoms between magnesium and titanium in the effective precatalyst (Scheme 5.9, step $\mathbf{b} \rightarrow \mathbf{d}$ ), slowing the dissociation of the $\mathbf{M g X}_{2}$ unit.

Figure 5.10. Ethene polymerization activity by the precatalysts prepared from $\mathrm{Mg} / \mathrm{Cl} /\left(\right.$ thf) salt (25) and $\mathrm{Mg} / \mathrm{Cl} /\left(\mathrm{OEt}_{2}\right)$ salt(27), derived from ligand 7, and $\mathrm{TiX}_{4}$. The data from 25 are the same as those used in Figure 5.8. Co-catalyst: $\mathrm{Me}_{3} \mathrm{Al}$ ( 100 $\mathrm{Al} / \mathrm{Ti}$ ).

(d)
$\mathrm{MgX}_{2}$ (solv)
dissociated

Scheme 5.9. The suggested transfer-steps of solvate molecules (solv) in the $\mathbf{M g} / \mathrm{Ti}$ precatalyst.

Chapter 5 5.2. The Magnesium Effect page 242

The precatalysts prepared from the non-solvated magnesium salt 83 did not show high polymerization activity, as shown in Figure 5.11. The lack of solvating ether may affect the solubility of the magnesium salt and/or the precatalyst in toluene.

Figure 5.11. Ethene polymerization activity by the precatalysts prepared from $(\mathrm{PhO})_{2} \mathbf{M g}(83)+0.1 \mathrm{MgCl}_{2} \bullet\left(\mathrm{OEt}_{2}\right)$ and $\mathrm{TiX}_{4}$. Co-catalyst: $\mathrm{Me}_{3} \mathrm{Al}(100 \mathrm{Al} / \mathrm{Ti})$.

The absence of halide in the starting magnesium salt 83 should not be the problem, because halides are provided by the $\mathrm{TiX}_{4}$. The stoichiometry of $\mathrm{MgX}_{2}$ relative to titanium is obviously affected, but a $1: 1$ ratio of $\mathrm{MgX}_{2}$ and Ti functions well for many other salts.

The presence of different halides and solvates clearly affected the stability of the precatalysts, but the activity of the catalysts remained at the typical magnesium-effect level. Therefore, it may be concluded that halides and solvate molecules are involved in the precatalysts prepared in situ from the aryloxymagnesium salts and $\mathrm{TiX}_{4}$ and have secondary influences on the catalyst activity.

Chapter 5 5.2. The Magnesium Effect page 243

### 5.2.F. In Situ Precatalyst Generation Using AI/Mg complexes: Importance of $\mathrm{Mg} / \mathrm{Ti}$ Ratio

The $\mathrm{Al} / \mathrm{Mg}$ hetero-polymetallic complexes 41 and 42 (Figure 5.12) also exhibit high polymerization activity when the precatalysts are generated by analogous in situ methods. Although the presence of aluminum is distinctive, we attribute the high activity to the magnesium effect, based on a similar dependence on mixing-time (effective catalysts are formed only within a short mixing period), similar activity range, and confirmed inertness of the final $\mathrm{Al} / \mathrm{Ti}$ product 46 (see Table 5.1), that forms after a prolonged mixing time.

41

42

25

Figure 5.12. Structures of 41, 42 and 25.

The polymerization activities at various ligand : titanium ratios and mixing times are summarized in Table $\mathbf{5 . 1 0}$ and 5.11. A short mixing time of 1 minute was evaluated in all series, with the longer mixing time checked only for limited cases. The co-catalyst used was M-MAO in all cases.

Table 5.10. Ethene polymerization activity by the precatalysts prepared from 41 and $\mathrm{TiCl}_{4}$.

| Entry | Ligand:Ti | Mix. time (min) | Activity (kg PE: $\mathrm{hr}^{-10}$ $\mathrm{mol} \mathrm{Ti}^{1} \mathrm{oarm}^{-1}$ ) |
| :---: | :---: | :---: | :---: |
| 121 | 1:1 | 1 | 335 |
| 122 |  | 80 | 31 |
| 123 | 1:2 | 1 | 518 |
| 124 |  | 81 | 43 |
| 125 | 1:3 | I | 445 |
| 126 | 1:4 | 1 | 425 |

Table 5.11. Ethene polymerization activity by the precatalysts prepared from 42 and $\mathrm{TiCl}_{4}$.

| Entry | Ligand:Ti | Mix. time (min) | Activity <br>  mol $\pi^{\top}$ oatm ${ }^{-1}$ ) |
| :---: | :---: | :---: | :---: |
| 131 | 1:1 | 1 | 715 |
| 132 |  | 63 | 75 |
| 133 | 1:2 | 1 | 659 |
| 134 |  | 60 | 324 |
| 135 |  | 43 hr | 61 |
| 136 | 1:3 | 1 | 443 |
| 137 | 1:4 | 1 | 354 |

The highest activity catalyst derived from the $\mathrm{Al} / \mathrm{Mg} / \mathrm{Mg}$ complex 41 was observed for the ligand : Ti ratio of $1: 2$, whereas for the $\mathrm{Al} / \mathrm{Mg} / \mathrm{Al}$ complex 42 , the ligand : Ti ratio was $1: 1$. For the analogous trinuclear magnesium complex 25 (see Figure 5.12), the highest activity with M-MAO was observed at a ligand : Ti stoichiometry of $1: 4$.

We suspect that the best stoichiometry of $\mathrm{TiCl}_{4}$ is not based on the ratio of ligand : Ti, but instead on the ratio of $\mathbf{M g}: \mathbf{T i}$. The best ligand : Ti ratios for precatalysts $\mathbf{2 5}, 41$ and 42 convert to $\mathrm{Mg}: \mathrm{Ti}$ ratios of $1: 1.3,1: 1$ and $1: 1$, respectively. In this series of $\mathbf{M g}$ and $\mathrm{Al} / \mathrm{Mg}$ derivatives from ligand 7, it thus appears that the ideal ratio of $\mathrm{Mg}: \mathrm{Ti}$ is about 1:1.

The magnesium salt of phenol, $77\left[\mathrm{PhOMgCl}(\mathrm{thf})_{2}\right]$, also showed the highest activity at a similar Mg : Ti ratio: at $1: 1$ returning $485 \mathrm{~kg} \mathrm{PE} \cdot \stackrel{ }{ }{ }^{-1} \cdot \mathrm{~mol} \mathrm{Ti}^{-1} \cdot a \mathrm{~atm}^{-1}$ vs. 282 kg PE $\bullet \mathrm{hr}^{-1} \cdot \mathrm{~mol} \mathrm{Ti}^{-1} \bullet \mathrm{~atm}^{-1}$ for a Mg : Ti ratio of $2: 1$ (co-catalyst: M-MAO). Using $\mathrm{Me}_{3} \mathrm{Al}$ as a co-catalyst, the relative activity was inverted, with higher activity for the greater ratio of $\mathrm{Mg}: \mathrm{Ti}(2: 1)$ than for the equimolar case, although the maximum activity was nearly comparable ( 550 vs. $484 \mathrm{~kg} \mathrm{PE} \cdot \mathrm{hr}^{-1} \cdot \mathrm{~mol} \mathrm{Ti}{ }^{-1} \cdot \mathrm{~atm}^{-1}$ ). The maximum activity was also more comparable for the "isolated" phenoxide $\mathrm{Mg} / \mathrm{Ti}$ precatalyst series $\mathbf{8 4}, \mathbf{8 5}$, and 86 (Section 5.2.D) activated by $\mathrm{Et}_{3} \mathrm{Al}$. The optimal activities for 25, 41, 42, and 77 (both
from in situ preparation of precatalysts and isolated $\mathbf{M g} / \mathrm{Ti}$ precatalysts) at various $\mathbf{M g}$ : Ti ratios are compared in the graph of activity vs. Ti/Mg ratio, provided in Figure 5.13.

Figure 5.13. Polymerization activity vs. $\mathrm{Ti} / \mathrm{Mg}$ ratio: from precatalysts prepared in situ from $41,42,25$ or 77 with $\mathrm{TiCl}_{4}$, and the isolated precatalysts [77+ $\mathrm{nTiCl}_{4}$ ] ( $\mathrm{n}=0.5,1$ and $2: 84,85$, and 86 respectively). Co-catalyst is M-MAO, except for the isolated precatalysts, for which $\mathrm{Et}_{3} \mathrm{Al}$ was used.

### 5.2.G. Advantages of Preorganization

### 5.2.G.1. Polydispersity

It has thus been shown that in the magnesium effect, the aryloxide ligand structure is only of secondary importance, mainly affecting the precatalyst solubility and the best mixing time. One specific advantage of the preorganized ligand system, however, was found to be the narrower molecular weight distribution of the product polyethene.

Because the polyethene product from the magnesium precatalyst method generally had very high molecular weights, both high-temperature polymerization and $\mathbf{H}_{2}$-incorporated polymerization reactions were performed to shift the average molecular weight to lower values. ${ }^{10}$

Chapter 5 5.2. The Magnesium Effect page 246
i) Results from high temperature polymerization. The polymer obtained from higher temperature conditions $\left(86-87{ }^{\circ} \mathrm{C}\right.$ ) lowered the molecular weight sufficiently to enable the GPC analysis. "The data for the polymer from the magnesium salt of ligand 7 (25) and from the magnesium phenoxide 77 (as isolated precatalyst 85) are summarized in Table 5.12. Polymerization reactions were performed following the "large-scale" procedure (Section 5.4.D), to provide better control of the temperature and to monitor the temperature change and ethene consumption. The conditions used were selected from the optimized small-scale series of experiments conducted for each magnesium salt. The activity values of each reaction will be discussed in more detail in a later section (5.2.G.2).

Table 5.12. GPC analyses of the polyethene from high temperature polymerization reactions I and II. Analysis was repeated twice for each sample.

| Reaction | Activity <br> (kg PEohrio mol $\left.\pi^{1 \text { eamm }}{ }^{-1}\right)$ | $M_{\mathrm{n}}$ | $M_{w}$ | $M_{W} / M_{\text {n }}$ |

| II | 275 | $3.94 \times 10^{4}$ | $1.98 \times 10^{5}$ | 5.04 |
|  |  | $3.96 \times 10^{4}$ | $1.99 \times 10^{5}$ | 5.03 |

Reaction I: $\quad 25+4 \mathrm{TiCl}_{4}(5 \mathrm{~min}) ; \mathrm{M}-\mathrm{MAO}(200 \mathrm{Al} / \mathrm{Ti}) ; 87^{\circ} \mathrm{C}$.
Reaction II: $\quad\left[77+1 \mathrm{TiCl}_{4}\right.$ (isolated precatalyst 85$\left.)\right] ; \mathrm{Et}_{3} \mathrm{Al}(120 \mathrm{Al} / \mathrm{Ti}) ; 85^{\circ} \mathrm{C}$.
Definitions: ${ }^{12}$
$M_{\mathrm{n}}=$ number average molecular weight
$M_{w}=$ weight average molecular weight $M_{w} / M_{\mathrm{n}}$ : polydispersity

The polyethene from the preorganized ligand system (Reaction $I$ ) has polydispersity clearly narrower than that from the simple phenoxide (Reaction II). However, the polydispersity of $>3$ is not narrow enough to indicate the formation of a single site catalyst, the ultimate goal of this ligand design investigation. The difference in polydispersity between these cases probably arises from the reduced degree of randomness imposed by the preorganized aryloxide ligand framework, as compared to the non-organized simple phenoxide.
ii) Results from $\mathbf{H}_{\mathbf{2}}$-incorporated polymerization. Hydrogen-incorporation experiments were done by using the small-scale procedure, which allowed the performance of many reactions in order to obtain a more thorough comparison. Table 5.13 summarizes the precatalyst/co-catalyst combinations and the data from GPC analyses. Entries 1-8 present the results from the precatalyst prepared from the magnesium salts 25 and 77 with $\mathrm{TiCl}_{4}$. The partial pressure of hydrogen and ethene was 0.13 and 3 atm , respectively.

${ }^{2.6}$ Average of four runs. The \% Error (a) or standard deviation (b) is given in parentheses.
${ }^{\mathbf{c}}$ Re-evaluation of the same polymer product obtained from Reaction I/ in Table 5.10.

Entry 9 is the repetition of the GPC analysis of the polymer obtained from Reaction II of Table 5.12, to calibrate the reproducibility of the GPC analysis. Note that this polyethene showed a polydispersity of $\sim 6$, broader than that obtained from the

Chapter 5 5.2. The Magnesium Effect page 248
previous analysis by $20 \%$. GPC analysis is affected by machine conditions and the way the baseline is determined. ${ }^{13}$

Under hydrogen partial pressure, the difference between the preorganized system (25) and the simple phenoxide (77) is not as clear as the difference determined under the high temperature conditions. The polydispersity of the polymer obtained from 25 and both M-MAO and $\mathrm{Me}_{3} \mathrm{Al}$ was narrower than that obtained from 77, while the polydispersity of the polymer obtained from 25 and $\mathrm{Et}_{3} \mathrm{Al}$ gave a broader polydispersity.

The presence of hydrogen affected the polymerization performance in these reactions, although the effect is greatly dependent on the co-catalyst used. Table 5.14 is the summary of polymerization activity obtained in the presence and absence of hydrogen as a function of the co-catalyst. Activity generally diminished for all cases when hydrogen was incorporated, but the extent of the effect for the magnesium salt 25 was most significant when using $\mathrm{Et}_{3} \mathrm{Al}$ as a co-catalyst (entries 5-6).
$\mathrm{Et}_{3} \mathrm{Al}$ thus has a negative effect on both polymerization activity and polydispersity. While it is not certain if a correlation exists between the causes of each effect, this sensitivity toward the co-catalyst nevertheless suggests the co-catalyst's involvement in the structure of the actual catalytic species. The reasons why $\mathrm{Et}_{3} \mathrm{Al}$ exerts a more profound influence than either $\mathrm{Me}_{3} \mathrm{Al}$ or $\mathrm{M}-\mathrm{MAO}$ are not well understood at this time.

Table 5.14. Activity of ethene polymerization reactions in the presence and absence of hydrogen partial pressure.

${ }^{\text {a }}$ The mixing time for the non $-\mathrm{H}_{2}$ experiment is different from the corresponding $\mathrm{H}_{2}$ incorporation experiment for these cases.

### 5.2.G.2. Thermal Robustness of the Catalyst

The magnesium salt 25 from the preorganized ligand system 7 showed a second advantage: high thermal robustness. Both magnesium salts 25 and 77 provided long catalyst lifetimes, but the former retained a high reaction rate at elevated temperature.

Figures 5.14 and 5.15 provide the temperature and ethene flow-rate ${ }^{14}$ profiles of polymerization reactions catalyzed by the precatalysts prepared from magnesium salts 25 (derived from ligand 7) or 77 (derived from phenol), by using the large-scale procedure (Section 5.4.D). The stoichiometry, co-catalyst, and mixing time were selected from the corresponding small-scale series for optimal performance. Each catalyst was evaluated at

Chapter 5 5.2. The Magnesium Effect page 250
two external temperatures: $31-32^{\circ} \mathrm{C}$ and $86-87^{\circ} \mathrm{C}$. The higher temperature experiment using precatalyst 25 is the same one used for the determination of polydispersity, as discussed in 5.2.G.1-i (Reaction I, Table 5.12).

At $31-32{ }^{\circ} \mathrm{C}$, both catalysts maintained strong ethene flow-rates for at least 30 minutes (Figures 5.14-a for 25 and Figure 5.15-a for 77). The relative rate of ethene uptake was higher for the former catalyst over the measured period. The higher rate is also reflected in the total activity value over the entire reaction time ( 640 vs .548 kg $\mathrm{PE} \cdot \mathrm{hr}^{-1} \cdot \mathrm{~mol} \mathrm{Ti}^{-1} \cdot \mathrm{~atm}^{-1}$ ). The rate decreased more rapidly, however, was faster for the former catalyst than that of the latter during the polymerization reaction. The catalyst lifetime was longer for the simple phenoxide 77, which maintained a steady reaction rate for over four hours. The increase in the ethene flow-rate observed after 3 hours is tentatively attributed to the growth in the polymer particles, which absorbed most of the solvent and exposed the catalysts directly to the ethene atmosphere.

At $86-87^{\circ} \mathrm{C}$, despite the expected decrease of ethene solubility in toluene at elevated temperature, the polymerization activity by the catalyst derived from 25 was considerably higher than at $31-32{ }^{\circ} \mathrm{C}$. The activity was $841 \mathrm{~kg} \mathrm{PE} \cdot \mathrm{hr}^{-1} \cdot \mathrm{~mol} \mathrm{Ti}^{-1} \cdot \mathrm{~atm}^{-1}$ over 40 minutes at $86-87{ }^{\circ} \mathrm{C}$ (Figure 5.14-b) while the value of $640 \mathrm{~kg} \mathrm{PE} \cdot \mathrm{hr}^{-1} \cdot \mathrm{~mol}$ $\mathrm{Ti}^{-1} \cdot \mathrm{~atm}^{-1}$ was recorded at $31-32{ }^{\circ} \mathrm{C}$. In contrast, the catalyst prepared from simple phenoxide 77 experienced decreased activity at higher temperature ( $548 \mathrm{~kg} \mathrm{PE} \cdot \mathrm{ehr}{ }^{-1} \cdot \mathrm{~mol}$ $\mathrm{Ti}^{-1} \cdot \mathrm{~atm}^{-1}$ at $32{ }^{\circ} \mathrm{C}$ vs. 241 kg PEehr ${ }^{-1} \cdot \mathrm{~mol} \mathrm{Ti}{ }^{-1} \cdot \mathrm{~atm}^{-1}$ at $86^{\circ} \mathrm{C}$ ). At high temperature, the preorganized ligand system must contribute to the preservation of active catalytic species, while simple phenoxide does not. The lifetime of the catalyst, however, was again longer for the simple phenoxide system: the rate, although lower, did not drop over a one-hour reaction period, while the rate gradually decreased in polymerization reactions using in the preorganized precatalyst system.

Figures 5.14 ( $\mathbf{a} \& \mathbf{b}$ ). Temperature/flow-rate profiles of the catalyst prepared from $[7-4 \mathrm{H}] \mathrm{Mg}_{3} \mathrm{Cl}_{2}(\text { thf })_{2}(25)$ and 4 equiv. of $\mathrm{TiCl}_{4}$; Mixing time 5 min ; with co-catalyst M-MAO (200 Al/Ti).

(a) Base temperature : $31.5^{\circ} \mathrm{C}$.

Polymerization time: 60 min .
Quantity of $\mathrm{Ti}: 1.07 \times 10^{-5}$ moles.
Activity : $\mathbf{6 4 0} \mathbf{~ k g ~ P E \bullet h r}{ }^{-1} \cdot \mathrm{~mol} \mathrm{Ti}^{-1} \cdot \mathrm{~atm}^{-1}$.

(b) (Reaction I in Table 5.12)

Base temperature : $87{ }^{\circ} \mathrm{C}$.
Polymerization time: 40 min .
Quantity of Ti : $9.06 \times 10^{-6}$ moles.
Activity : $841 \mathrm{~kg} \mathrm{PE} \cdot \mathrm{hr}{ }^{-1} \cdot \mathrm{~mol} \mathrm{Ti}{ }^{-1} \cdot \mathrm{~atm}^{-1}$.

Figures 5.15 (a \& b). Temperature/flow-rate profiles of the catalyst prepared from $\mathrm{C}_{6} \mathrm{H}_{5} \mathrm{OMgCl}(\text { thf })_{2}(77)+0.5 \mathrm{TiCl}_{4}$; Mixing time 10 min ; with co-catalyst $\mathrm{Me}_{3} \mathrm{Al}(500 \mathrm{Al} / \mathrm{Ti})$

1. Base temperature : $32^{\circ} \mathrm{C}$.

Polymerization time: 4 hr 04 min .
Quantity of $\mathrm{Ti}: 7.58 \times 10^{-6}$ moles.
Activity : 548 kg PE $\cdot \mathrm{hr}^{-1} \cdot \mathrm{~mol} \mathrm{Ti}^{-1} \cdot \mathrm{~atm}^{-1}$.

1. Base temperature : $86^{\circ} \mathrm{C}$

Polymerization time: 54 min .
Quantity of $\mathrm{Ti}: 7.71 \times 10^{-6}$ moles.
Activity : $\mathbf{2 4 1} \mathbf{~ k g ~ P E \cdot h r}{ }^{-1} \cdot \mathrm{~mol} \mathrm{Ti}^{-1} \cdot \mathrm{~atm}^{-1}$.

Chapter 5 5.2. The Magnesium Effect page 253

It should be noted that the activity values obtained from large-scale experiments were generally improved over the corresponding polymerization reactions done at smallscale. A separate large-scale experiment using the conditions reported in Figure 5.14-a gave an activity of $1,030 \mathrm{~kg} \mathrm{PE}_{\mathrm{Ph}}{ }^{-1} \cdot \mathrm{~mol} \mathrm{Ti}^{-1} \cdot \mathrm{~atm}^{-1}$. This exceptional activity, however, was partly a function of the unusually short polymerization period ( 11.5 minutes) necessitated by the approximately threefold increase in the quantity of the catalyst ( 3.20 x $10^{-5}$ moles of Ti ) compared to that in the other large- and small-scale experiments, and the quick rise in temperature (from $31^{\circ} \mathrm{C}$ to $76^{\circ} \mathrm{C}$ within 7.5 minutes) caused by the high exothermicity of the polymerization.

### 5.3. Conclusion

Tetraarylethene-based Preorganized Polyaryloxide Ligand Systems. The titanium complexes of the tetraarylethene-based preorganized ligands (7, 3E and 3Z) were ineffective precatalysts for ethene polymerization. The $\mathrm{Mg} / \mathrm{Ti}$ and $\mathrm{Al} / \mathrm{Ti}$ heteropolymetallic complexes developed from ligand 7 were also inert. These systems do not seem to be promising templates for constructing model systems for Ziegler-Natta catalysts based on titanium alone. Other metals with different valencies, such as the Group 3 metals, Ti(III), Group 5, and Group 6 metals in appropriate oxidation states, may be useful for future work. Because the ligand system is oxygen-based, modeling other silica-supported catalysts, such as the chromium-based Phillips catalyst, ${ }^{15}$ may be a reasonable subject for future research.

Oxygen atoms as donor groups may also not be ideal to create catalytic species. Nitrogen-based donor groups are used in latest non-metallocene homogeneous catalysts, such as amides and imines, ${ }^{16}$ which can give 1,000 -fold higher ethene polymerization activities than those of classic heterogeneous Ziegler-Natta catalysts. ${ }^{17,18}$ Imine-based ligands are particularly useful for late-group metals, often as neutral catalytic species. ${ }^{172}$ Introduction of donor heteroatoms other than oxygen into the tetraarylethene framework may create different binding sites more suitable for high-activity polymerization catalysts.

Magnesium Effect. The characteristics of the magnesium effect suggest that the actual catalyst formed from magnesium precatalysts resembles the $\mathbf{M g C l}_{2}$-supported $\mathbf{T i C l}_{\mathbf{4}}$ heterogeneous Ziegler-Natta catalysts. It is unfortunate that the effective precatalysts have too short a lifetime for isolation, structural characterization, and further investigation as models for such heterogeneous systems. Isolation of the magnesiumincorporated precatalysts was possible for the simple phenoxide system, but structural analyses of the isolated precatalysts were not possible.

Preorganization of multiple phenoxide units contributed to the narrower polydispersity of the polymer and the thermal robustness of the catalyst, but the desired "single-site" behavior was not attained. Preorganization presumably functions to reduce the uncontrolled aggregation of the precatalysts or catalysts, compared to that of the simple phenoxide system.

The Fluorene-Based Ligand System. The titanium complexes from the fluorene-diol ligand 4 showed promising catalytic activity without assistance from magnesium. Further research is warranted to determine if the dinuclear titanium structure is involved in creating the catalytic site and if this system can serve as a model for heterogeneous catalysts. Although the difficulty in synthesizing the ligand discouraged further research, an alternative dibenzofuran-diol system with the same basic structure of the fluorenyl system is currently under investigation.

### 5.4. Experimental

Instrumental, General and Materials: see Chapter 3, Section 3.4 Experimental.

Instrumental (additional): Gel permeation chromatography (GPC) analysis of polyethene samples were performed at the Department of Chemical and Materials Engineering (Professor Wanke's lab) on Alliance GPCV 2000 using a refractive index detector using $1,2,4$-trichlorobenzene as a solvent at a flow-rate of $1 \mathrm{~mL} / \mathrm{min}$. and $140^{\circ} \mathrm{C}$. Polymer samples were dissolved in trichlorobenzene at $160^{\circ} \mathrm{C}$ before injection.

General (additional): All preparations of the metal derivatives were performed in the drybox. The solutions or suspensions for the polymerization reactions were prepared in the drybox, and the polymerization reactions were performed out of the drybox under the purified ethene atmosphere (see below).

Materials (additional): Ethene and hydrogen gases were purchased from Praxair and purified by passage through a gas purification unit, which consists of columns of copper deoxygenation catalyst and of 13X and 3A molecular sieves. M-MAO as a solution in toluene ( $7.1 \mathrm{wt} \% \mathrm{Al}$ ) was purchased from Akzo-Nobel and stored in the drybox in the original metal cylinder. Toluene for polymerization experiments was kept "ethereal-solvent-free" as described in Chapter 3, 3.4. Experimental. The synthesis of 2,7-bis(1,1-dimethylethyl)-9H-fluorene-1,8-diol 4 is described in Chapter 1 .

### 5.4.A. Preparation of Metal Derivatives

The preparation of the following derivatives were described in earlier chapters: Ti complexes 31,34 and $35, \mathrm{Mg} / \mathrm{Ti}$ complex 45 , $\mathrm{Al} / \mathrm{Ti}$ complex $46, \mathrm{Mg}$ complexes $\mathbf{2 5}, 26$ and 27, Na salt 40 and $\mathrm{Mg} / \mathrm{Al}$ complexes 41 and 42 (Chapter 3); Ti complex 52 and AI complexes 47, 48 and 50 (Chapter 4).

## 71: $\left.\left[2,7 \text {-di-f-butylfluorene-1,8-( } \mathrm{OTCC}_{3}\right)_{2}\right]^{4}$

To the solution of 2,7 -bis(1,1-dimethylethyl)-9H-fluorene-1,8-diol (4) $(0.0245 \mathrm{~g}, 0.0789$ mmol ) in 0.5 mL of toluene was added $\mathrm{NaH}(0.0102 \mathrm{~g}, 0.425 \mathrm{mmol})$ suspended in 1 mL
of toluene. After $0.5 \mathrm{~h}, \mathrm{TiCl}_{4}(0.30 \mathrm{~g}, 1.6 \mathrm{mmol})$ dissolved in toluene ( 2 mL ) was added to the mixture. The color immediately turned dark red. After 0.5 h , the volatiles were removed in vacuo, the residue was triturated with pentane to remove excess $\mathrm{TiCl}_{4}$, then triturated with toluene. The pentane triturate, after slow evaporation, resulted in prism crystals. The toluene triturate resulted in semi-crystalline material. Both were identified as 71 by ${ }^{1} \mathrm{H}$ NMR spectroscopy, identical to the data reported by Wuest et al. ${ }^{4}$ The yields were not recorded.

## 72: [2,7-di-t-butyIfluorene-1,8-\{OTiCl $\left.\mathbf{3}^{(t h f)}\right\}_{2}$ ]

To the suspension of magnesium salt 74 (prepared the same way as presented below, but not analyzed; formula weight was assumed to be $572 ; 0.020 \mathrm{~g}, 0.035 \mathrm{mmol}$ ) in 3 mL of toluene was added $\mathrm{TiCl}_{4}(0.05 \mathrm{~mL}, 0.46 \mathrm{mmol})$. The mixture turned dark red immediately. After 1 h , the mixture was filtered through Celite-packed pipette, and the volatiles were removed from the filtrate in vacuo. The residue was triturated with pentane, filtered, and crystallized from toluene-hexanes (slow evaporation). Large prism crystals of very dark red color were formed. X-ray crystallographic analysis of the crystals revealed the structure of 72 as a THF solvate, with no involvement of magnesium. The yield was not recorded. X-ray crystallography: see Appendix A-23.

## 74: $\mathbf{M g} / \mathrm{CV} /($ thf) salt of 4

After mixing 2,7-bis(1,1-dimethylethyl)-9H-fluorene-1,8-diol (4) ( $0.0234 \mathrm{~g}, 0.0754$ mmol ) and $\mathrm{CH}_{3} \mathrm{MgCl}(0.3 \mathrm{M} / \mathrm{THF}, 0.51 \mathrm{~mL}, 0.81 \mathrm{mmol})$ in THF ( 1 mL ) overnight, the volatiles were removed from the clear solution in vacuo, and the residue was crystallized from toluene (r.t. $-30^{\circ} \mathrm{C}$ ). The white solid produced was, however, not very crystalline. The solid was collected, washed with pentane and dried in vacuo ( $0.0395 \mathrm{~g}, 77 \%$ ). Anal. Found (average of two runs): C, $56.93( \pm 0.60) ; H, 6.88( \pm 0.08)$. Formula: $\mathrm{C}_{21} \mathrm{H}_{24} \mathrm{O}_{2} \cdot \mathrm{Mg}_{2.5}{ }^{\circ} \mathrm{Cl}_{3.0}{ }^{\circ}(\text { thf })_{2.8}$. Formula weight: 679. For calculation of formula and formula weight, see Section 5.4.B.

General preparation procedure for magnesium salts 75, 76, 77, 78, 79, 82, and 83.
The general form of the magnesium salts of phenolic ligands prepared for this investigation is $\left[\mathrm{Ar}(\mathrm{O})_{o}\right] \cdot \mathrm{Mg}_{m} \cdot \mathrm{X}_{n} \cdot(\text { solv })_{p}$, in which $\left[\mathrm{Ar}(\mathrm{O})_{0}\right]$ is the deprotonated ligand, o is the number of aryloxy donors per ligand molecule, $m, n$ and $p$ are the stoichiometry of $\mathrm{Mg}, \mathrm{X}$ (either Cl or Br ) and coordinating solvent (either THF or $\mathrm{Et}_{2} \mathrm{O}$ ) per ligand. $\left[\operatorname{Ar}(\mathrm{O})_{o}\right] \cdot \mathrm{Mg}_{m} \cdot \mathrm{X}_{n} \cdot(\text { solv })_{p}$ is prepared from a phenolic ligand $\left[\operatorname{Ar}(\mathrm{OH})_{0}\right]$ by adding $o$ equivalent(s) of Grignard reagent $\mathrm{RMgX} /($ solv) to the ligand dissolved in the same
solvent, or in some cases toluene, at room temperature for several hours to overnight. The precipitate produced in the reaction was collected, washed with the same reaction solvent to remove excess reagent or ligand, followed by pentane to remove less volatile solvents, and dried in vacuo. The formula and formula weight are calculated from the elemental analysis by the method described in the following section (5.4.B).

## 75: $\mathbf{M g} / \mathrm{Cl}$ salt of 3 E

After mixing $E$-bis(2-hydroxyphenyl)-bis(2-methoxyphenyl)ethene (3E) ( 0.1665 g , 0.3922 mmol ) and $\mathrm{CH}_{3} \mathrm{MgCl}(0.3 \mathrm{M} / \mathrm{THF}, 2.6 \mathrm{~mL}, 0.78 \mathrm{mmol}$ ) in THF ( 1 mL ) for overnight, the white precipitate was collected, washed and dried as described in the general procedure. The particles were so tiny, some went through the glass-fritted funnel during the filtration and washing. Yield is not recorded. Anal. Found: C, 74.75; H, 5.00. Formula: $\mathrm{C}_{26} \mathrm{H}_{22} \mathrm{O}_{4} \bullet \mathrm{Mg}_{1.1} \bullet \mathrm{Cl}_{0.1}$ (THF content was calculated as below 0.1 equiv.). Formula weight: 452.

## 76: $\mathbf{M g} / \mathrm{Cl}$ (thf) salt of $\mathbf{3 Z}$

After mixing Z-bis(2-hydroxyphenyl)-bis(2-methoxyphenyl)ethene (3Z) ( $0.0582 \mathrm{~g}, 0.137$ mmol ) and $\mathrm{CH}_{3} \mathrm{MgCl}(0.3 \mathrm{M} / \mathrm{THF}, 0.92 \mathrm{~mL}, 0.28 \mathrm{mmol}$ ) in toluene ( 1 mL ) for overnight, the white precipitate was collected, washed and dried as described in the general procedure ( $0.045 \mathrm{~g}, 65 \%$ ). Anal. Found (average of two runs): C, 67.43 ( $\pm 0.18$ ); H, 4.54 $( \pm 0.04)$. Formula: $\mathrm{C}_{26} \mathrm{H}_{22} \mathrm{O}_{4} \cdot \mathrm{Mg}_{1.3} \cdot \mathrm{Cl}_{0.6}{ }^{\circ}(\text { thf })_{0.7}$. Formula weight: 505.

## 77: $\mathbf{M g} / \mathrm{Cl} /($ thf) salt of phenol

After mixing phenol ( $0.462 \mathrm{~g}, 4.91 \mathrm{mmol}$ ) and $\mathrm{CH}_{3} \mathrm{MgCl}$ ( $3 \mathrm{M} / \mathrm{THF}, 1.7 \mathrm{~mL}, 5.1 \mathrm{mmol}$ ) in THF ( 5 mL ) for overnight, the white precipitate was collected, washed and dried as described in the general procedure ( $1.09 \mathrm{~g}, 73 \%$ ). Anal. Found: C, 55.96; H, 7.08. Formula: $\mathrm{C}_{6} \mathrm{H}_{5} \mathrm{O} \cdot \mathrm{Mg}_{1.05}{ }^{\bullet} \mathrm{Cl}_{1.1}(\text { thf })_{2.1}$. Formula weight: 306 . A small amount of the product was recrystallized from THF (r.t. $\rightarrow-30{ }^{\circ} \mathrm{C}$ ). Preliminary X-ray analysis of the crystals revealed the dimeric structure (Figure 5.16). ${ }^{19}$

Figure 5.16. Preliminary X-ray crystallographic structure of 77.

78: $\mathbf{M g} / \mathrm{CL} /($ thf $)$ salt of $\mathbf{3 , 3} \mathbf{3}^{\prime}$-dimethyl-4,4'-biphenol
After mixing 3,3'-dimethyl-4,4'-biphenol ( $0.0459 \mathrm{~g}, 0.214 \mathrm{mmol}$ ) and $\mathrm{CH}_{3} \mathbf{M g C l}$ ( $3 \mathrm{M} / \mathrm{THF}, 0.18 \mathrm{~mL}, 0.54 \mathrm{mmol}$ ) in THF ( 4 mL ) for overnight, the white precipitate was collected, washed and dried as described in the general procedure. Yield is not recorded. Anal. Found (average of two runs): C, 55.23 ( $\pm 0.32$ ); H, $6.13( \pm 0.08)$. Formula: $\mathrm{C}_{14} \mathrm{H}_{12} \mathrm{O}_{2} \cdot \mathrm{Mg}_{1.3} \cdot \mathrm{Cl}_{0.6}$ (thf) $)_{2.4}$. Formula weight: 514.

## 79: $\mathbf{M g} / \mathrm{Cl}($ (thf) salt of $\mathbf{4 , 4}$ '-hydroquinone

After mixing 4,4'-hydroquinone ( $0.1204 \mathrm{~g}, 1.09 \mathrm{mmol}$ ) and $\mathrm{CH}_{3} \mathrm{MgCl}$ (3M/THF, 0.76 $\mathrm{mL}, 2.3 \mathrm{mmol}$ ) in THF ( 6 mL ) for overnight, the white precipitate was collected, washed with THF and dried in vacuo. Yield is not recorded. Anal. Found: C, 41.33; H, 5.17. Formula: $\mathrm{C}_{6} \mathrm{H}_{4} \mathrm{O}_{2}{ }^{\bullet} \mathrm{Mg}_{2.1} \bullet \mathrm{Cl}_{2.2}(\mathrm{thf})_{1.4}$. Formula weight: 342 .

## 82: $\mathbf{M g} / \mathbf{B r} /($ thf $)$ salt of phenol

After mixing phenol ( $0.3891 \mathrm{~g}, 4.13 \mathrm{mmol}$ ) and $\mathrm{CH}_{2}=\mathrm{CHCH}_{2} \mathrm{MgBr}\left(1 \mathrm{M} / \mathrm{Et}_{2} \mathrm{O}, 4.45 \mathrm{~mL}\right.$, 4.45 mmol ) in THF ( 10 mL ) for overnight, the white precipitate was collected, washed with THF and dried in vacuo ( $1.1244 \mathrm{~g}, 76.5 \%$ ). Anal. Found: C, $48.75( \pm 0.10) ; \mathrm{H}, 6.20$ ( $\pm 0.07$ ). Formula: $\mathrm{C}_{6} \mathrm{H}_{5} \mathrm{O} \bullet \mathrm{Mg}_{1.0}{ }^{\circ} \mathrm{Cl}_{\mathrm{I} .1}(\text { thf })_{2.1}$. Formula weight: 356 .

## 83: $\mathbf{M g} / \mathrm{Cl}$ salt of phenol

After mixing phenol ( $0.752 \mathrm{~g}, 7.99 \mathrm{mmol}$ ) and $\mathrm{BnMgCl}\left(1,0 \mathrm{M} / \mathrm{Et}_{2} \mathrm{O}, 4.45 \mathrm{~mL}, 4.45\right.$ mmol ) in $\mathrm{Et}_{2} \mathrm{O}(10 \mathrm{~mL})$ for overnight, the white precipitate was collected, washed with
$\mathrm{Et}_{2} \mathrm{O}$, and dried in vacuo ( $0.4676 \mathrm{~g}, 48 \%$ ). Anal. Found (average of two runs): C, 63.96 ( $\pm 0.62$ ); $\mathrm{H}, 5.11( \pm 0.08)$. Formula: $\mathrm{C}_{6} \mathrm{H}_{5} \mathrm{O} \cdot \mathrm{Mg}_{0.58}{ }^{\circ} \mathrm{Cl}_{0.16}\left(\mathrm{OEt}_{2}\right)_{0.12}$. Formula weight: 121.

General preparation of sodium salts $\mathbf{7 3}, 80$ and 81. Sodium salts $\mathbf{7 3}, 80$ and 81 were prepared by mixing the phenolic ligand $\left[\mathrm{Ar}(\mathrm{OH})_{o}\right]$ and $o$ equivalent of NaH in toluene. THF was used as a co-solvent only when immediate gas evolution was not observed. The precipitate was collected, washed with toluene, followed by pentane, and dried in vacuo. The formula of the product is assumed as $\left[\operatorname{Ar}(\mathrm{ONa})_{o}\right]$. The formula weight provided is based on this formula.

## 73: Na salt of 4

After mixing 2,7-bis(1,1-dimethylethyl)-9H-fluorene-1,8-diol (4) ( $0.0090 \mathrm{~g}, 0.029 \mathrm{mmol}$ ) and $\mathrm{NaH}(0.0014 \mathrm{~g}, 0.058 \mathrm{mmol})$ in toluene ( 2 mL ) for overnight, co-solvent THF ( 1 mL ) was added and the mixture was stirred again overnight. The slightly pink precipitate was collected, washed and dried as described in the general procedure. The yield was not recorded. Formula (assumed): $\mathrm{C}_{21} \mathrm{H}_{24} \mathrm{O}_{2} \bullet \mathrm{Na}_{2}$. Formula weight (assumed): 354.

## 80: Na salt of phenol

After mixing phenol ( $0.263 \mathrm{~g}, 2.80 \mathrm{mmol}$ ) and $\mathrm{NaH}(0.0654 \mathrm{~g}, 2.73 \mathrm{mmol})$ in toluene ( 6 mL ) for overnight, the white precipitate was collected, washed and dried as described in the general procedure ( $0.2632 \mathrm{~g}, 84 \%$ ). Formula (assumed): $\mathrm{C}_{6} \mathrm{H}_{5} \mathrm{O} \cdot \mathrm{Na}$. Formula weight (assumed): 116.

## 81: Na salt of 4,4'-hydroquinone.

After mixing 4,4'-hydroquinone ( $0.1845 \mathrm{~g}, 1.676 \mathrm{mmol}$ ) and $\mathrm{NaH}(0.0804 \mathrm{~g}, 3.35 \mathrm{mmol})$ in toluene ( 5 mL ) for overnight, co-solvent THF ( 3 mL ) was added and the mixture was stirred again overnight. The gray precipitate was collected, washed and dried as described in the general procedure. The yield was not recorded. Formula (assumed): $\mathrm{C}_{6} \mathrm{H}_{4} \mathrm{O}_{2} \cdot \mathrm{Na}_{2}$. Formula weight (assumed): 154.

## 84: Isolated $\mathbf{M g}$ Ti precatalyst of phenoxide ligand ( $\mathbf{M g}: \mathbf{T i}=2: 1$ )

To the suspension of magnesium salt 77 ( $0.141 \mathrm{~g}, 0.461 \mathrm{mmol}$ ) in 4 mL of hexanes was added $\mathrm{TiCl}_{4}(0.0440 \mathrm{~g}, 0.232 \mathrm{mmol})$ dissolved in 4 mL of hexanes. The color turned orange immediately. After 6 h , the orange precipitate was collected, washed with hexanes, and dried in vacuo ( 0.1750 g ). The supernatant and washings were combined,

Chapter 5 5.4. Experimental page 260
and the residue after removal of the volatiles in vacuo weighed 0.0061 g . It is thus assumed that the starting materials were mostly transformed into the precipitate. The yield is $\mathbf{9 7 \%}$, assuming the formula of the adduct to be $\left(\mathrm{C}_{6} \mathrm{H}_{5} \mathrm{O}\right)_{2}{ }^{2} \mathbf{M g}_{2}{ }^{\circ} \mathbf{T i}^{-} \mathrm{Cl}_{6}{ }^{\circ}(\text { (thf })_{4}$ (calc. formula weight: 784). Anal. Calc. for $\mathrm{C}_{28} \mathrm{H}_{42} \mathrm{Cl}_{6} \mathrm{Mg}_{2} \mathrm{O}_{6}$ Ti: C. 42.91; H. 5.40. Found (average of two runs): C, $41.60( \pm 0.17) ; \mathrm{H}, 5.27( \pm 0.06)$.

## 85: Isolated $\mathbf{M g} / \mathrm{Ti}$ precatalyst of phenoxide ligand ( $\mathbf{M g}: \mathbf{T i}=1: \mathbf{1}$ )

To the suspension of magnesium salt $77(0.0854 \mathrm{~g}, 0.285 \mathrm{mmol})$ in 3 mL of toluene was added $\mathrm{TiCl}_{4}(0.0546 \mathrm{~g}, 0.288 \mathrm{mmol})$ dissolved in 1 mL of toluene. The color turned red immediately. After 6 h , the precipitate with brick-red color was collected, washed with toluene, and dried in vacuo ( 0.1466 g ). The supernatant and washings were combined, and the residue after removal of the volatiles in vacuo weighed 0.0071 g . It is thus assumed that the starting materials were mostly transformed into the precipitate. The yield is $\mathbf{9 7 \%}$, assuming the formula of the adduct to be $\mathrm{C}_{6} \mathrm{H}_{5} \mathrm{O} \cdot \mathrm{Mg}^{\circ} \mathrm{Ti}^{\circ} \cdot \mathrm{Cl}_{5}{ }^{\circ}(\text { (thf })_{2}$ (calc. formula weight: 487). Anal. Calc. for $\mathrm{C}_{14} \mathrm{H}_{21} \mathrm{Cl}_{5} \mathrm{MgO}_{3} \mathrm{Ti}$ : C. 34.55; H. 4.35. Found (average of two runs): C, $39.26( \pm 0.17) ; \mathrm{H}, 4.84$ ( $\pm 0.04$ ).

## 86: Isolated $\mathbf{M g}$ Ti precatalyst of phenoxide ligand ( $\mathbf{M g}: \mathbf{T i}=\mathbf{1 : 2}$ )

To the suspension of magnesium salt $77(0.125 \mathrm{~g}, 0.408 \mathrm{mmol})$ in 3 mL of hexanes was added $\mathrm{TiCl}_{4}(0.1584 \mathrm{~g}, 0.8350 \mathrm{mmol})$ dissolved in 2 mL of hexanes. The color turned orange immediately, then red-orange. After overnight, the precipitate with brickred/brown color was collected, washed with hexanes, and dried in vacuo ( 0.2317 g ). The supernatant and washings were combined, and the residue after removal of the volatiles in vacuo weighed 0.0086 g . It is thus assumed that the starting materials were mostly transformed into the precipitate. The yield is $84 \%$, assuming the formula of the adduct to be $\mathrm{C}_{6} \mathrm{H}_{5} \mathrm{O} \cdot \mathrm{Mg}^{\circ} \cdot \mathrm{Ti}_{2} \cdot \mathrm{Cl}_{9} \bullet(\text { thf })_{2}$ (calc. formula weight: 676). Anal. Calc. for $\mathrm{C}_{14} \mathrm{H}_{21} \mathrm{Cl}_{9} \mathrm{MgO}_{3} \mathrm{Ti}_{2}$ : C. 24.86; H. 3.13. Found (average of two runs): C, $27.75( \pm 0.06) ; \mathrm{H}$, $3.35( \pm 0.01)$.

### 5.4.B. Composition of Mg salts: Calculations based on Elemental Analysis

The compositions of the magnesium salts were calculated from the carbon/hydrogen elemental analysis data and theoretical charge balance of ions, using the general formulae described below.

For a salt $\mathrm{C}_{c} \mathrm{H}_{\mathrm{h}} \mathrm{O}_{0} \cdot \mathrm{Mg}_{m} \cdot \mathrm{X}_{n} \cdot\left(\mathrm{C}_{4} \mathrm{H}_{y} \mathrm{O}\right)_{p}$ with formula weight FW :
$\mathrm{C}_{\mathrm{c}} \mathrm{H}_{\mathrm{h}} \mathrm{O}_{\mathrm{o}}$ is the ligand, deprotonated form.
$\mathrm{c}, \mathrm{h}$ and o are integers specific to the ligand. For example, in deprotonated phenol $\left(\mathrm{C}_{6} \mathrm{H}_{5} \mathrm{O}\right), c=6, h=5$ and $\mathrm{o}=1$; in deprotonated ligand 7, $\mathrm{c}=38, h=$ 40 and $o=4$.
$y$ is an integer specific to the coordinating solvent: $y=8$ for THF, $y=10$ for diethyl ether.
X is halogen atom, either Cl or Br .
$m$ and $n$ are the ratio of Mg and X atoms per ligand.
$p$ is the ratio of the coordination solvent (THF or ether) per ligand.
$p, m, n$ and FW are the unknown values to be calculated.

$$
\underline{\mathrm{FW}} \text { of } \mathrm{C}_{c} \mathrm{H}_{\mathrm{h}} \mathrm{O}_{0} \bullet \mathrm{Mg}_{m} \bullet X_{n} \bullet\left(\mathrm{C}_{4} \mathrm{H}_{y} \mathrm{O}\right)_{\mathrm{p}}=(\mathrm{c}+4 \mathrm{p}) \mathrm{C} \bullet(\mathrm{~h}+\mathrm{yp}) \mathrm{H} \bullet(\mathrm{o}+\mathrm{p}) \mathrm{O} \bullet m \mathrm{Mg} \bullet \mathrm{n} \mathbf{X}
$$

Thus:

$$
\begin{equation*}
\underline{\mathrm{FW}}=\mathrm{M}_{\mathrm{C}}(\mathrm{c}+4 p)+\mathrm{M}_{\mathrm{H}}(\mathrm{~h}+\mathrm{y} p)+\mathrm{M}_{\mathrm{o}}(0+p)+2 \mathrm{M}_{\mathrm{M}_{\mathrm{g}}} m+\mathrm{M}_{\mathrm{x}} n \tag{Eq.5-1}
\end{equation*}
$$

$\mathrm{M}_{\mathrm{C}}, \mathrm{M}_{\mathrm{H}}$ and $\mathrm{M}_{\mathrm{O}}$ and $\mathrm{M}_{\mathrm{Mg}}$ are atomic weights of $\mathrm{C}, \mathrm{H}$ and $\mathrm{O} . \mathrm{M}_{\mathrm{c}}=12.011, \mathrm{M}_{\mathrm{H}}$ $=1.008$ and $\mathrm{M}_{\mathrm{O}}=15.995$.
$\mathrm{M}_{\mathrm{x}}$ is an atomic weight of the corresponding halogen atom: $\mathrm{Mx}=34.453$ for Cl , and $\mathrm{Mx}=\mathbf{7 9 . 9 0 4}$ for Br .

$$
\mathrm{FW}=12.011(\mathrm{c}+4 p)+1.008(\mathrm{~h}+\mathrm{yp})+15.999(\mathrm{o}+p)+24.305 m+\mathrm{M}_{\mathrm{x}} n
$$

Thus:
$1=12.011(\mathrm{c}+4 p) / \mathrm{FW}+1.008(\mathrm{~h}+\mathrm{yp}) / \mathrm{FW}+15.999(\mathrm{o}+p) / \mathrm{FW}+24.305 \mathrm{~m} / \mathrm{FW}+$ 35.453n/FW

Chapter 5 5.4. Experimental page 262

The first two terms of the right side are related to C/H elemental analysis data as follows.

$$
\begin{align*}
& 12.011(\mathrm{c}+4 p) / \mathrm{FW}=[\text { C EA } \%] / 100  \tag{Eq.5-2}\\
& 1.008(\mathrm{~h}+\mathrm{yp}) / \mathrm{FW}=[\mathrm{H} \text { EA } \%] / 100 \tag{Eq.5-3}
\end{align*}
$$

[C EA \%] and [H EA \%] are the \% elemental compositions of C and H , as determined by combustion analysis.

From Eqs. 5-2 and 5-3,

$$
\begin{align*}
& p=\left([\mathrm{HEA} \%] \cdot 12.011{ }^{\circ} \mathrm{C}-[\mathrm{CEA} \%] \cdot 1.008 \cdot \mathrm{~h}\right)  \tag{Eq.5-4}\\
& \text { ([C EA \%]-1.008॰y - [H EA \%]-12.011•4) } \\
& F W=\underline{12.011(c+4 p) \cdot 100}=\underline{1.008(h+y p) \cdot 100}  \tag{Eq.5-5}\\
& \text { [C EA \%] [HEA \%] }
\end{align*}
$$

To obtain $m$ and $n$ from FW, $\boldsymbol{p}$ and mass/charge balances,
$[$ Mass of $\mathrm{Mg}+\mathrm{X}]=\underline{\mathrm{FW}}-$ [mass of deprotonated ligand $]-\mathrm{M}_{\mathbf{s}} \bullet \boldsymbol{p}$
[Mass of $\mathrm{Mg}+\mathrm{X}$ ] is the portion of Mg plus X in the formula weight of the salt.
$\mathbf{M}_{s}$ is the molecular weight of the coordinating solvent: $\mathbf{M}_{s}=72.11$ for THF ; and $M_{s}=74.12$ for diethyl ether.
[Mass of $\mathrm{Mg}, \mathrm{X}]=\mathbf{2 4 . 3 0 m}+\mathrm{M}_{5} \boldsymbol{n}$
$2 m=0+n$

Eq. 5-7 reflects the mass balance of the Mg and X portions in the formula.
Eq. 5-8 reflects the charge balance of the anions (the deprotonated ligand and halide) and the cation (magnesium ion).

### 5.4.C. Small-Scale Polymerization Experiments

Precatalysts, either Ti complexes or hetero-polymetallic precatalysts prepared in situ, were first examined for ethene polymerization reactivity in the small-scale trials: typically, titanium complexes or main-group metal salts in combination with appropriate stoichiometry of $\mathrm{TiCl}_{4}$, both with Ti content of $1-7 \times 10^{-6} \mathrm{~mol}$, were used as precatalysts, along with $5-7 \mathrm{~mL}$ of toluene as a solvent. The pressure of ethene was 30 psig for all experiments, including hydrogen-incorporation experiments. The initial temperature was ambient and was uncontrolled during the polymerization reaction. The temperature rises substantially within minutes for very active catalysts. The polymerization time was up to 10 minutes, but when the catalyst was very active, the reaction was terminated after a few minutes to avoid stirring problems.

The pressure-tight reaction vessels purchased from Lab Glass ( 20 mL , LG-3922-100) were used for all small-scale polymerization reactions. Fitting gaskets and crown caps were used to seal the vessels. Gaskets were wrapped with Teflon tape by at least threefold to avoid poisoning of the precatalysts. Lubricant-free plastic syringes, purchased from Aldrich (Z23,072-3), were used to convey, measure, and inject toluene-solutions of $\mathrm{TiX}_{4}$ and aluminum co-catalysts. The co-catalyst was either $\mathrm{Me}_{3} \mathrm{Al}(100 \mathrm{Al} / \mathrm{Ti}), \mathrm{Et}_{3} \mathrm{Al}$ ( $100 \mathrm{Al} / \mathrm{Ti}$ ), or M-MAO ( $200 \mathrm{Al} / \mathrm{Ti}$ ), used as a toluene solution. Purified ethene and hydrogen gases are introduced to the reaction vessel via a gas line equipped with syringeneedle terminals.

Three general procedures are provided in the following: (1) polymerization reaction using Ti complexes as precatalysts; (2) polymerization reaction using precatalysts prepared in situ from main group metal salts and $\mathrm{TiX}_{4}$; and (3) hydrogen-incorporated polymerization reactions. The complete data, including quantities of the precatalysts, the stoichiometry, and the activity of the polymerization catalysis that appear in this chapter will be provided in Section 5.4.E.
(1) Polymerization reaction using Ti complexes or isolated $\mathbf{M g} / \mathrm{Ti}$ precatalysts. In the drybox, a solution/suspension of the titanium complex (1 to 5 mg ) in 5 mL of toluene was prepared in a pressure-tight reaction vessel which contained a magnetic rod for stirring, and sealed with a gasket and a crown cap. Out of the drybox, ethene ( 30 psig ) was introduced into the reaction vessel via a needle terminal while the
suspension/solution was vigorously stirred. The nitrogen gas was purged by repeatedly pressurizing with ethene to 30 psig and releasing the pressure at least five times. The solution of co-catalyst in toluene was injected into the mixture via syringe to initiate the polymerization. After 10 minutes, or when the mixture became thick with polymer particles to the point stirring became difficult, the reaction vessel was isolated from the ethene source, the pressure was released via a syringe needle through the gasket, and a solution of conc. $\mathrm{HCl} / \mathrm{EtOH}$ ( $1 / 40$ ratio, 2 mL ) was injected immediately. The polymer was collected, washed with the $\mathrm{HCl} / \mathrm{EtOH}$ solution, and dried under reduced pressure at $40^{\circ} \mathrm{C}$ overnight.
(2) Polymerization reaction using precatalysts prepared in situ from main-group metal salts and TiX 4 . In the drybox, a solution/suspension of the main-group metal salt (ca. 1 to 4 mg ) in 5 mL of toluene was prepared in a pressure-tight reaction vessel which contained a magnetic rod for stirring, and sealed with a gasket and a crown cap. Out of the drybox, ethene ( 30 psig ) was introduced to the reaction vessel via a needle terminal while the suspension/solution was vigorously stirred. The nitrogen gas was purged by repeating pressurizing with ethene to 30 psig and venting the pressure at least five times. A solution of $\mathrm{TiX}_{4}$ in toluene, prepared and measured in the drybox in a lubricant-free disposable syringe, was then injected for a designated mixing time. ${ }^{2}$ The solution of co-catalyst in toluene was then injected to the mixture via syringe to initiate the polymerization. After 10 minutes, or when the mixture gets thick with polymer particles to the point that stirring is difficult, the reaction vessel was isolated from the ethene source, the pressure was released via a syringe needle through the gasket, and the solution of conc. $\mathrm{HCl} / \mathrm{EtOH}$ ( $1 / 40$ ratio, 2 mL ) was injected immediately. The polymer was collected, washed with the $\mathrm{HCl} / \mathrm{EtOH}$ solution, and dried under reduced pressure at $40^{\circ} \mathrm{C}$ ovemight.
(3) Hydrogen-incorporated polymerization reaction. In the drybox, a solution/suspension of the main-group metal salt (ca. 1 to 4 mg ) in 5 mL of toluene was prepared in a pressure-tight reaction vessel which contained a magnetic rod for stirring, and sealed with a gasket and a crown cap. Out of the drybox, ethene ( 30 psig ) was introduced to the reaction vessel via a needle terminal while the suspension/solution was vigorously stirred. The nitrogen gas was purged by repeating pressurizing with ethene to $(30+p)$ psig ( $p=$ designated partial pressure of hydrogen) and venting the pressure at

[^18]Chapter 5 5.4. Experimental page 265
least five times. The ethene pressure was released to 0 psig, the stopcock between the reaction vessel and the gas line was closed, then the gas line was filled with hydrogen at the designated pressure ( $\boldsymbol{p}$ psig). The hydrogen was introduced by opening the stopcock between the vessel and the gas line, while the mixture was vigorously stirred. The stopcock was closed again, the gas line was flushed with ethene at $(30+p)$ psig, and the vessel was pressurized by opening the stopcock. A solution of $\mathrm{TiX}_{4}$ in toluene, prepared and measured in the drybox in a lubricant-free disposable syringe, was then injected to the hydrogen-capped mixture for the designated mixing time. The solution of co-catalyst in toluene was then injected to the mixture via syringe to initiate the polymerization. After 10 minutes, or when the mixture became thick with polymer particles to the point the stirring was difficult, the reaction vessel was isolated from the ethene source, the pressure was released via a syringe needle through the gasket, and the solution of conc. $\mathrm{HCl} / \mathrm{EtOH}(1 / 40 \mathrm{v} / \mathrm{v}, 2 \mathrm{~mL}$ ) was injected immediately. The polymer was collected, washed with the $\mathrm{HCl} / \mathrm{EtOH}$ solution, and dried under reduced pressure at $40{ }^{\circ} \mathrm{C}$ overnight.

### 5.4.D. Large-Scale Polymerization Experiments

Large-scale experiments were performed for selected catalyst conditions, to obtain temperature and ethene flow-rate profiles and to investigate the catalyst lifetime over a prolonged period. All experiments were to evaluate the precatalysts prepared from selected magnesium salts ( 25 and 77), under 30 psig of ethene, at a semi-controlled external temperature of either $31-32{ }^{\circ} \mathrm{C}$ or $86-87^{\circ} \mathrm{C}$. The external temperature was regulated in an ethylene glycol bath, connected to the Neslab Circulating Cooler RTE211. These reactions involved the use of similar quantities of precatalysts as used in the small-scale reactions, but using ca. 170 mL of solvent. The reaction vessel was purchased from Andrews Glass Co., equipped with a Lab Crest 110-900-0012 multiported stirring assembly mounted with a type J thermocouple, injection port, vacuum/gas release port combined with a safety valve. To perform polymerization reactions, the reaction vessel was equipped with a pressure-tight addition funnel that can be connected to the reaction vessel via a Swagelok quick-connector fitting and a Parr 4841 controller assembly with mechanical stirrer and temperature control/monitoring devices. The glass container, the stirring blades, and the thermocouple terminal of the reaction vessel were rinsed with neat tri-iso-butylaluminum, followed by polymerization-quality toluene in the drybox, prior to
use. Ethene flow-rate (uncalibrated) was detected by an ethene mass flowmeter (Teledyne-Hastings-Raydist) connected to a recorder (Fisher recordall series 5000).

A general procedure is provided below, followed by the specific descriptions of the largescale polymerization experiments discussed in this chapter.

## General procedure of large-scale experiments.

In the drybox, the solution of the designated amount of the co-catalyst in 160 mL of toluene was prepared in the reaction vessel, which was then sealed with the stirring assesmbly. The pressure-tight addition funnel was also charged with the solution/suspension of the magnesium salt in $6-11 \mathrm{~mL}$ of toluene (see specific descriptions below). Out of the drybox, the reaction vessel was equipped with the addition funnel the reaction vessel was placed under ethene pressure ( 30 psig ), and nitrogen gas was purged by repeating pressurizing with ethene and venting the pressure at least five times. The atmosphere of the addition funnel was also flushed with ethene. At the same time, the reaction vessel was placed in the temperature-adjusted ethylene glycol bath. The temperature of the reaction mixture was monitored using the type $J$ thermocouple. When the temperature was equilibrated, the solution of $\mathrm{TiCl}_{4}$ in toluene, prepared and measured in the drybox in a lubricant-free disposable syringe, was injected to the suspension/solution of the magnesium salt in the addition funnel. Occasional swirling was applied during the designated mixing time. The content of the addition funnel was then added to the co-catalyst solution in the reaction vessel to initiate the polymerization by release the pressure of the vessel slightly and repressurize from the top of the addition funnel. The pressure of the main reactor was regained immediately. The addition funnel was rinsed with 4 mL of fresh toluene, and the rinsing was also added to the reaction vessel by the same procedure. The ethene flow-rate and temperature were recorded during the polymerization, typically over 0.5 h . The reaction was terminated by isolating the reaction vessel from the ethene source, releasing the pressure, and injecting 5 mL of conc. $\mathrm{HCl} / \mathrm{EtOH}(1 / 40, \mathrm{v} / \mathrm{v})$. The polymer was collected, washed with the $\mathrm{HCl} / \mathrm{EtOH}$ solution, and dried under reduced pressure at $40^{\circ} \mathrm{C}$ overnight.

Polymerization by [ $25+4 \mathrm{TiCl}_{4}\left(5 \mathrm{~min}\right.$ of mixing time)], M-MAO, $87{ }^{\circ} \mathrm{C}$ (Table 5.12, Reaction I).
To the solution of M-MAO ( $2.31 \times 10^{-3} \mathrm{~mol} \mathrm{Al} / \mathrm{mL}$ toluene, $0.78 \mathrm{~mL}, 1.8 \times 10^{-3} \mathrm{~mol}$ ) in toluene ( 160 mL ) in the reaction vessel, vigorously stirred at $87^{\circ} \mathrm{C}$ under ethene pressure ( 30 psig ), was added the precatalyst suspension that was prepared by mixing magnesium

Chapter 5 5.4. Experimental page 267
salt 25 ( $\mathrm{FW}=965,0.0022 \mathrm{~g}, 2.3 \times 10^{-6} \mathrm{~mol}$ ) and $\mathrm{TiCl}_{4}(3.35 \mathrm{~mol} / \mathrm{mL}$ toluene, 0.27 mL , $9.1 \times 10^{-6} \mathrm{~mol}$ ) in 6 mL of toluene for 5 min in the addition funnel. The addition funnel was rinsed with 4 mL of toluene and the rinsing was added to the reaction mixture. The polymerization reaction was quenched after 40 min by releasing the pressure and injecting the solution of conc. $\mathrm{HCl} / \mathrm{EtOH}(2 \mathrm{~mL}$ ). The yield of the product polymer was 15.23 g . The polymerization activity was $841 \mathrm{~kg} \mathrm{PE} \cdot \mathrm{hr}^{-1} \cdot \mathrm{~mol} \mathrm{Ti}^{-1} \cdot a \mathrm{~atm}^{-1}$.

## Polymerization by [25 + 4TiCl 4 ( 5 min of mixing time)], M-MAO, $31.5{ }^{\circ} \mathrm{C}$ (Figure 5.14-a).

To the solution of M-MAO ( $2.31 \times 10^{-3} \mathrm{~mol} \mathrm{Al} / \mathrm{mL}$ toluene, $0.93 \mathrm{~mL}, 2.1 \times 10^{-3} \mathrm{~mol}$ ) in toluene ( 160 mL ) in the reaction vessel, vigorously stirred at $31.5^{\circ} \mathrm{C}$ under ethene pressure ( 30 psig ), was added the precatalyst suspension that was prepared by mixing magnesium salt 25 ( $\mathrm{FW}=965,0.0022 \mathrm{~g}, 2.3 \times 10^{-6} \mathrm{~mol}$ ) and $\mathrm{TiCl}_{4}(3.35 \mathrm{~mol} / \mathrm{mL}$ toluene, $0.32 \mathrm{~mL}, 1.1 \times 10^{-5} \mathrm{~mol}$ ) in 11 mL of toluene for 5 min in the addition funnel. The addition funnel was rinsed with 4 mL of toluene and the rinsing was added to the reaction mixture. The polymerization reaction was quenched after 60 min by releasing the pressure and injecting the solution of conc. $\mathrm{HCl} / \mathrm{EtOH}(2 \mathrm{~mL})$. The yield of the product polymer was 20.53 g . The polymerization activity was $640 \mathrm{~kg} \mathrm{PE} \cdot \mathrm{hr}^{-1} \cdot \mathrm{~mol} \mathrm{Ti}^{-1} \cdot \mathrm{~atm}^{-1}$.

## Polymerization by [25 $+4 \mathrm{TiCl}_{4}\left(5 \mathrm{~min}\right.$ of mixing time)], M-MAO, $31.5^{\circ} \mathrm{C}$ (Section

 5.2.G.2).To the solution of M-MAO ( $7.1 \mathrm{wt} \% \mathrm{Al}, 2.4443 \mathrm{~g}, 6.4 \times 10^{-3} \mathrm{~mol}$ ) in toluene ( 163 mL ) in the reaction vessel, vigorously stirred at $31{ }^{\circ} \mathrm{C}$ under ethene pressure ( 30 psig ), was added the precatalyst suspension that was prepared by mixing magnesium salt 25 ( $\mathrm{FW}=939$, $\left.0.0075 \mathrm{~g}, 8.0 \times 10^{-6} \mathrm{~mol}\right)$ and $\mathrm{TiCl}_{4}\left(3.33 \times 10^{-5} \mathrm{~mol} / \mathrm{mL}\right.$ toluene, $\left.0.96 \mathrm{~mL}, 3.2 \times 10^{-5} \mathrm{~mol}\right)$ in 10 mL of toluene for 10 min in the addition funnel. The addition funnel was rinsed with 4 mL of toluene and the rinsing was added to the reaction mixture. Significant rise in temperature up to $66^{\circ} \mathrm{C}$ was observed within 7 min , accompanied by rapid formation of polymer particles. The reaction had to be quenched after 11.5 min , because the mixture became think with polymer particles. The yield of the product polymer was 18.98 g . The polymerization activity was $1,030 \mathrm{~kg} \mathrm{PE} \cdot h r^{-1} \cdot \mathrm{~mol} \mathrm{Ti}^{-1} \cdot \mathrm{~atm}^{-1}$.

## Polymerization by Isolated precatalyst $85\left[77+\mathrm{TiCl}_{4}\right], \mathrm{Et}_{3} \mathrm{Al}, 85{ }^{\circ} \mathrm{C}$ (Table 5.12, Reaction II).

To the solution of $\mathrm{Et}_{3} \mathrm{Al}\left(1.11 \times 10^{-3} \mathrm{~mol} \mathrm{Al} / \mathrm{mL}\right.$ toluene, $\left.0.58 \mathrm{~mL}, 6.4 \times 10^{-3} \mathrm{~mol}\right)$ in toluene ( 160 mL ) in the reaction vessel, vigorously stirred at $87.5^{\circ} \mathrm{C}$ under ethene pressure ( 30 psig ), was added the precatalyst suspension of $85\left(0.0026 \mathrm{~g}, 5.3 \times 10^{-6} \mathbf{~ m o l}\right.$ )
in 11 mL of toluene. The addition funnel was rinsed with 4 mL of toluene and the rinsing was added to the reaction mixture. The polymerization reaction was quenched after 60 $\min$ by releasing the pressure and injecting the solution of conc. $\mathrm{HCl} / \mathrm{EtOH}(2 \mathrm{~mL})$. The polymerization activity was $275 \mathrm{~kg} \mathrm{PE}_{\mathrm{P}} \mathrm{Pr}^{-1} \cdot \mathrm{~mol} \mathrm{Ti}^{-1} \cdot \mathrm{~atm}^{-1}$.

## Polymerization by [77 + 0.5TiCl $\mathbf{4}_{4}\left(10 \mathrm{~min}\right.$ of mixing time) , $\mathrm{Me}_{3} \mathrm{Al}, 32^{\circ} \mathrm{C}$ (Figure 5.15-a).

To the solution of $\mathrm{Me}_{3} \mathrm{Al}\left(0.277 \mathrm{~g}, 3.85 \times 10^{-3} \mathrm{~mol}\right)$ in toluene $(160 \mathrm{~mL})$ in the reaction vessel, vigorously stirred at $32{ }^{\circ} \mathrm{C}$ under ethene pressure ( 30 psig ), was added the precatalyst suspension that was prepared by mixing magnesium salt $77(0.0045 \mathrm{~g}, 1.5 \mathrm{x}$ $10^{-6} \mathrm{~mol}$ ) and $\mathrm{TiCl}_{4}\left(8.33 \times 10^{-6} \mathrm{~mol} / \mathrm{mL}\right.$ toluene, $\left.0.91 \mathrm{~mL}, 7.6 \times 10^{-6} \mathrm{~mol}\right)$ in 11 mL of toluene for 10 min in the addition funnel. The addition funnel was rinsed with 4 mL of toluene and the rinsing was added to the reaction mixture. The polymerization reaction was quenched after 244 min by releasing the pressure and injecting the solution of conc. $\mathrm{HCl} / \mathrm{EtOH}$ ( 2 mL ). The yield of the product polymer was 49.87 g . The polymerization activity was $548 \mathrm{~kg} \mathrm{PE} \cdot \mathrm{hr}^{-1} \cdot \mathrm{~mol} \mathrm{Ti}^{-1} \cdot \mathrm{~atm}^{-1}$.

## Polymerization by [77 $+\mathbf{0 . 5 T i C l} 4$ ( 10 min of mixing time)]; $\mathrm{Me}_{3} \mathrm{Al}, 86{ }^{\circ} \mathrm{C}$ (Figure 5.15-b).

To the solution of $\mathrm{Me}_{3} \mathrm{Al}\left(0.279 \mathrm{~g}, 3.86 \times 10^{-3} \mathrm{~mol}\right)$ in toluene ( 160 mL ) in the reaction vessel, vigorously stirred at $86{ }^{\circ} \mathrm{C}$ under ethene pressure ( 30 psig ), was added the precatalyst suspension that was prepared by mixing magnesium salt $77(0.0045 \mathrm{~g}, 1.5 \mathrm{x}$ $10^{-6} \mathrm{~mol}$ ) and $\mathrm{TiCl}_{4}\left(3.35 \times 10^{-5} \mathrm{~mol} / \mathrm{mL}\right.$ toluene, $\left.0.23 \mathrm{~mL}, 7.7 \times 10^{-6} \mathrm{~mol}\right)$ in 11 mL of toluene for 10 min in the addition funnel. The addition funnel was rinsed with 4 mL of toluene and the rinsing was added to the reaction mixture. The polymerization reaction was quenched after 54 min by releasing the pressure and injecting the solution of conc. $\mathrm{HCl} / \mathrm{EtOH}$ ( 2 mL ). The yield of the product polymer was 5.01 g . The polymerization activity was $241 \mathrm{~kg} \mathrm{PE} \cdot \mathrm{hr}^{-1} \cdot \mathrm{~mol} \mathrm{Ti}^{-1} \cdot \mathrm{~atm}^{-1}$.

### 5.4.E. Complete Data of Polymerization Reactions

This section provides the specific conditions and activity values of all the small-scale polymerization reactions that were presented in this chapter, in the order of appearance. The general procedures were provided in Section 5.4.C. The ethene pressure was consistently 30 psig, which was converted to ca. 45 psia, thus to 3 atm .
(1) Conditions and results for the polymerization reactions in Table 5.1. The first column corresponds to the entries in Table 5.1.

Chapter 5 5.5. page 282

[^20]
## General Conclusion

The modified tetrakis(2-hydroxyphenyl)ethene-based ligands were found to be promising templates for the construction of various discrete mononuclear and polynuclear metal complexes. The ortho-propylated derivative, tetrakis(2-hydroxy-3propylphenyl)ethene (7), showed diverse coordination patterns for polynuclear complexes of $\mathrm{Mg}(\mathrm{II}), \mathrm{Ti}(\mathrm{IV})$ and Al (III). The coordination patterns were largely determined by the metal species, probably most affected by the valency of the metal atoms. The dialkylated analogue, $E$-bis(2-hydroxyphenyl)-bis(2-methoxyphenyl)ethene $(3 E)$, provided several mononuclear Ti and Al complexes, as well as dinuclear and trinuclear species, which posess a mononuclear core attached to extra metal fragment(s) on the periphery. Comparison with the $Z$-analogue of the ligand, $3 Z$, showed the advantages of trans-dialkylation in the formation of discrete complexes.

Although the titanium derivatives of these ligands do not show potential as ethene polymerization catalysts, the ligands' capacity as an oxo-surface model merits further exploration. Floriani has investigated potential oxo-surface model chemistry of various transition metal complexes derived from the calix[4]arene ligand system. ${ }^{1}$ Very different chemical behavior, however, can be expected from the tetraarylethene-based systems, based on the ability to form polynuclear complexes on a single ligand. The reduced tendency to form collapsed 'sandwich-type' structure in ortho-propylated ligand 7 will be particularly advantageous, because such dimerization is a problem often encountered in calix[4]arene systems.

The potential of the divalent $E$-dialkylated ligand $\mathbf{3 E}$ as an alternative ancillary ligand for metallocenes, especially for Group 4 metals, may also be an interesting topic. Little is known about the extent to which the ancillary ligand determines reactivity in organometallic chemistry of the Group 4 metals. ${ }^{2}$ Floriani, et. al., has shown that zirconium complexes of the dialkylated calix-[4]-arene ligand exhibit different reactivity than simple zirconocene complexes in the insertion chemistry of dialkylzirconium complexes ${ }^{3}$ and butadiene complexes. ${ }^{2}$ The similar but different tetraarylethene framework in ligand 3E may provide a platform for divergent chemical behavior as well.

The possibilities for coordination chemistry widen upon introduction of other heteroatom binding sites into the tetraarylethene template. The easiest approach is to modify the hydroxy termini with nitrogen- or phsphorous-containing groups, which will be suitable for late transition-metal binding, as recently demonstrated done for calixarene systems. ${ }^{4}$

The newly developed tetrakis(2-hydroxyphenyl)ethene template and metal derivatives may serve as new oxo-surface model templates, as well as new support ligands for various metals in exploratory organometallic chemistry and catalysis.

A-2: 13. Cis-4b,9b-Dihydro-4b,9b-bis(2-hydroxyphenyl)benzofuro(3,2b)benzofuran

- Chapter I -

SDL Code: JMS9902
Date: 13 April 1999
Compound: $\quad\left\{\mathrm{C}\left(\mathrm{C}_{6} \mathrm{H}_{4}-2-\mathrm{OH}\right)\left(\mathrm{C}_{6} \mathrm{H}_{4}-2-\mathrm{O}-\right)\right\}_{2}{ }^{-} \mathrm{Et}_{2} \mathrm{O}$
Formula: $\quad \mathrm{C}_{30} \mathrm{H}_{28} \mathrm{O}_{5}\left(\mathrm{C}_{26} \mathrm{H}_{18} \mathrm{O}_{4}{ }^{\circ} \mathrm{C}_{4} \mathrm{H}_{10} \mathrm{O}\right)$

Figure 2. Alternate view showing the intra- $(\mathrm{Ol} \cdots \mathrm{H} 4=1.86 \AA)$ and intermolecular ( $\mathrm{O} 1 \mathrm{~S} \cdots \mathrm{H} 2=1.86 \AA$ ) hydrogen-bonded interactions within and between the $\left\{\mathrm{C}\left(\mathrm{C}_{6} \mathrm{H}_{4}-2\right.\right.$ $\left.\mathrm{OH})\left(\mathrm{C}_{6} \mathrm{H}_{4}-2-\mathrm{O}-\right)\right\}_{2}$ molecule and the solvent diethyl ether molecule.

> $0.807\left[F_{0}^{2} \geq-3 \sigma\left(F_{0}^{2}\right)\right]$
${ }^{a}$ Obtained from least-squares refinement of 1532 centered reflections.
${ }^{b}$ Programs for diffractometer operation, data collection, data reduction and absorption correction were those supplied by Bruker.
${ }^{\text {c S Sheldrick, G. M. Acta Crystallogr. 1990, A46, 467-473. }}$
${ }^{d}$ Sheldrick, G. M. SHELXL-93. Program for crystal structure determination. University of Göttingen, Germany, 1993. Refinement on $F_{0}{ }^{2}$ for all reflections (all of these having $F_{0}^{2} \geq-3 \sigma\left(F_{0}^{2}\right)$ ). Weighted $R$-factors $w R_{2}$ and all goodnesses of fit $S$ are based on $F_{0}^{2}$; conventional $R$-factors $R_{1}$ are based on $F_{0}$, with $F_{0}$ set to zero for negative $F_{0}^{2}$. The observed criterion of $F_{0}^{2}>2 \sigma\left(F_{0}^{2}\right)$ is used only for calculating $R_{1}$, and is not relevant to the choice of reflections for refinement. $R$-factors based on $F_{0}{ }^{2}$ are statistically about twice as large as those based on $F_{0}$, and $R$-factors based on ALL data will be even larger.
${ }^{e}$ No absorption correction was applied due to the small crystal size and low value of the linear absorption coefficient $(\mu)$.
$f S=\left[\Sigma w\left(F_{0}^{2}-F_{c^{2}}^{2}\right)^{2 /(n-p)}\right]^{1 / 2}(n=$ number of data; $p=$ number of parameters varied; $w$ $=\left[\sigma^{2}\left(F_{0}^{2}\right)+(0466 P)^{2}\right]^{-1}$ where $\left.P=\left[\operatorname{Max}\left(F_{0}^{2}, 0\right)+2 F_{\mathrm{c}}^{2}\right] / 3\right)$.
$g R_{1}=\Sigma| | F_{0}\left|-\left|F_{\mathrm{c}}\right|\right| \Sigma\left|F_{\mathrm{o}}\right| ; w R_{2}=\left[\Sigma w\left(F_{0}^{2}-F_{\mathrm{c}^{2}}\right)^{2} / \Sigma w\left(F_{0}^{4}\right)\right]^{1 / 2}$.

## A-3: Complex 26. $\left[\mathrm{C}_{38} \mathrm{H}_{40} \mathrm{O}_{4}\right]\{\mathrm{Mg}($ thf $)\}\{\mathrm{MgBr}(\text { thf })\}_{2}$

- Chapter 3 -

XCL Code: JMS0007
Date: $\quad 15$ March 2000
Compound: $\left[\mathrm{C}_{2}\left\{\mathrm{C}_{6} \mathrm{H}_{3}(3-\mathrm{nPr})(2-\mathrm{O}-)\right\}_{4}\right]\left\{\mathrm{Mg}\left(\mathrm{OC}_{4} \mathrm{H}_{8}\right)\right\}\left\{\mathrm{MgBr}\left(\mathrm{OC}_{4} \mathrm{H}_{8}\right)\right\}_{2}$
Formula: $\quad \mathrm{C}_{50} \mathrm{H}_{64} \mathrm{Br}_{2} \mathrm{Mg}_{3} \mathrm{O}_{7}$

Figure 1. Perspective view of the $\left[\left\{\mathrm{C}_{2}\left(\mathrm{C}_{6} \mathrm{H}_{3}\left\{{ }^{n} \mathrm{Pr}\right\}\{\mathrm{O}-\}\right)_{4}\right\} \mathrm{Mg}_{3} \mathrm{Br}_{2}\left(\mathrm{OC}_{4} \mathrm{H}_{8}\right)_{3}\right]$ molecule/ion showing the atom labelling scheme. Non-hydrogen atoms are represented by Gaussian ellipsoids at the $20 \%$ probability level. Hydrogen atoms are not shown. Primed atoms are related to unprimed ones via the crystallographic twofold rotational axis ( $0, y, 1 / 4$ ) passing through $\mathrm{MgI}, \mathrm{O}$, and the centers of the $\mathrm{Cl}-\mathrm{Cl}^{\prime}$ and $\mathrm{C} 32-\mathrm{C} 32$ ' bonds.

cSheldrick, G. M. Acta Crystallogr. 1990, A46, 467-473.
${ }^{d}$ Sheldrick, G. M. SHELXL-93. Program for crystal structure determination. University of Göttingen, Germany, 1993. Refinement on $F_{0}^{2}$ for all reflections (all of these having $F_{0}^{2} \geq-3 \sigma\left(F_{0}^{2}\right)$ ). Weighted $R$-factors $w R_{2}$ and all goodnesses of fit $S$ are based on $F_{0}^{2}$; conventional $R$-factors $R_{1}$ are based on $F_{0}$, with $F_{0}$ set to zero for negative $F_{0}^{2}$. The observed criterion of $F_{0}^{2}>2 \sigma\left(F_{0}^{2}\right)$ is used only for calculating $R_{1}$, and is not relevant to the choice of reflections for refinement. $R$-factors based on $F_{0}{ }^{2}$ are statistically about twice as large as those based on $F_{\mathrm{o}}$, and $R$-factors based on ALL data will be even larger.
e Distances within the disordered $n$-propyl group were given fixed idealized values: $\mathrm{d}(\mathrm{C} 27-\mathrm{C} 28 \mathrm{~A})=\mathrm{d}(\mathrm{C} 28 \mathrm{~A}-\mathrm{C} 29 \mathrm{~A})=\mathrm{d}(\mathrm{C} 27-\mathrm{C} 28 \mathrm{~B})=\mathrm{d}(\mathrm{C} 28 \mathrm{~B}-\mathrm{C} 29 \mathrm{~B})=1.54 \AA$.
$f F_{\mathrm{c}}{ }^{*}=k F_{\mathrm{c}}\left[1+x\left\{0.001 F_{\mathrm{c}}^{2} \lambda^{3} / \sin (2 \theta)\right\}\right]^{-1 / 4}$ where $k$ is the overall scale factor.
$s S=\left[\Sigma w\left(F_{0}^{2}-F_{\mathrm{c}}^{2}\right)^{2 /(n-p)}\right]^{1 / 2}(n=$ number of data; $p=$ number of parameters varied; $w$ $=\left[\sigma^{2}\left(F_{0}^{2}\right)+(0.2000 P)^{2}\right]^{-1}$ where $\left.P=\left[\operatorname{Max}\left(F_{0}^{2}, 0\right)+2 F_{\mathrm{c}}^{2}\right] / 3\right)$.
${ }^{h} R_{1}=\Sigma| | F_{0}\left|-\left|F_{\mathrm{c}}\right|\right| \Sigma\left|F_{\mathrm{o}}\right| ; w R_{2}=\left[\Sigma w\left(F_{\mathrm{o}}^{2}-F_{\mathrm{c}}{ }^{2}\right)^{2 / \Sigma} w\left(F_{\mathrm{o}}{ }^{4}\right)\right]^{1 / 2}$.

## A-4: Complex 28. $\left[\mathrm{C}_{\mathbf{3 8}} \mathrm{H}_{\mathbf{4 0}} \mathrm{O}_{\mathbf{4}}\right]\{\mathrm{Mg}($ thf $)\}\{\mathrm{MgMe}(\mathrm{thf})\}_{\mathbf{2}}$

- Chapter 3 -

XCL Code: JMSO045
Date: 13 February 2001
Compound: $\left[\mathrm{C}_{2}\left\{\mathrm{C}_{6} \mathrm{H}_{3}(3-n \mathrm{Pr})(2-\mathrm{O}-)\right\}_{4}\right]\left(\mathrm{Mg}\left(\mathrm{OC}_{4} \mathrm{H}_{8}\right)\right\}\left(\mathrm{Mg}\left(\mathrm{CH}_{3}\right)\left(\mathrm{OC}_{4} \mathrm{H}_{8}\right)\right\}_{2}$
Formula: $\quad \mathrm{C}_{52} \mathrm{H}_{70} \mathrm{Mg}_{3} \mathrm{O}_{7}$

Figure 1. Perspective view of the $\left[\left(\mathrm{C}_{2}\left\{\mathrm{C}_{6} \mathrm{H}_{3}\left({ }^{( }{ }^{\mathrm{Pr}}\right) \mathrm{O}\right\}_{4}\right)\left\{\mathrm{Mg}\left(\mathrm{OC}_{4} \mathrm{H}_{8}\right)\right\}\left(\mathrm{MgMe}\left(\mathrm{OC}_{4} \mathrm{H}_{8}\right)\right)_{2}\right]$ molecule showing the atom labelling scheme. Non-hydrogen atoms are represented by Gaussian ellipsoids at the $20 \%$ probability level. Hydrogen atoms are not shown. Primed atoms are related to unprimed ones via the crystallographic twofold rotational axis $(0,0, z)$, upon which the $\mathrm{Mgl}-\mathrm{O} 3$ bond is situated.

${ }^{a}$ Obtained from least-squares refinement of 7006 centered reflections.
${ }^{b}$ Programs for diffractometer operation, data collection, data reduction and absorption correction were those supplied by Bruker.
${ }^{c}$ Sheldrick, G. M. Acta Crystallogr. 1990, A46, 467-473.
${ }^{d}$ Sheldrick, G. M. SHELXL-93. Program for crystal structure determination. University of Göttingen, Germany, 1993. Refinement on $F_{0}{ }^{2}$ for all reflections (all of these having $F_{0}^{2} \geq-3 \sigma\left(F_{0}^{2}\right)$ ). Weighted $R$-factors $w R_{2}$ and all goodnesses of fit $S$ are based on $F_{0}{ }^{2}$; conventional $R$-factors $R_{1}$ are based on $F_{0}$, with $F_{0}$ set to zero for negative $F_{0}^{2}$. The observed criterion of $F_{0}^{2}>2 \sigma\left(F_{0}^{2}\right)$ is used only for calculating $R_{1}$, and is not relevant to the choice of reflections for refinement. $R$-factors based on $F_{0}{ }^{2}$ are statistically about twice as large as those based on $F_{0}$, and $R$-factors based on ALL data will be even larger.
${ }^{e}$ Flack, H. D. Acta Crystallogr. 1983, A39, 876-881. The Flack parameter will refine to a value near zero if the structure is in the correct configuration and will refine to a value near one for the inverted configuration.
$f_{S}=\left[\Sigma w\left(F_{0}^{2}-F_{\mathrm{c}}^{2}\right)^{2 /(n-p)}\right]^{1 / 2}(n=$ number of data; $p=$ number of parameters varied; $w$ $=\left[\sigma^{2}\left(F_{0}^{2}\right)+(0.0960 P)^{2}\right]^{-1}$ where $\left.P=\left[\operatorname{Max}\left(F_{0}^{2}, 0\right)+2 F_{c^{2}}^{2}\right] / 3\right)$.
$g_{R_{1}}=\Sigma| | F_{0}\left|-\left|F_{c}\right|\right| \Sigma\left|F_{0}\right| ; w R_{2}=\left[\Sigma w\left(F_{0}^{2}-F_{c^{2}}\right)^{\left.2 / \Sigma w\left(F_{0}^{4}\right)\right]^{1 / 2} .}\right.$

Primed atoms are related to unprimed ones via the crystallographic twofold axis $(0,0, z)$.

Table 6. Least-Squares Planes

| Plane |  | Coefficients $^{a}$ |  |  | Defining Atoms with Deviations $(\AA)^{b}$ |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| I | 0.0 | 0.0 | $15.6366(18)$ | $2.4229(12)$ |  |  |  |  |
|  |  |  |  | O1 | $-0.0042(11)$ | O2 | $0.0042(11)$ |  |
|  |  |  |  | O1' | $-0.0042(11)$ | O2' | $0.0042(11)$ |  |
|  |  |  |  |  |  | Mg1 | $0.1471(17)$ |  |
|  |  |  |  | Mg2 | $0.6881(15)$ |  |  |  |

${ }^{a}$ Coefficients are for the form $a x+b y+c z=d$ where $x, y$ and $z$ are crystallographic coordinates.
${ }^{b}$ Underlined atoms were not included in the definition of the plane.

## A-5: Co-crystal of 30a and 32. $\left[\mathrm{C}_{38} \mathrm{H}_{40} \mathrm{O}_{4}\right]$-gem-anti- $\left\{\mathrm{TiCl}_{2}(\text { (thf })\right\}_{2} /$ $\left[\mathrm{C}_{38} \mathrm{H}_{40} \mathrm{O}_{4}\right]_{2} \mathrm{Ti}_{\mathbf{2}}$

- Chapter 3 -

XCL Code: JMS0020
Date: 5 April 2001
Compound: $\quad\left[\mathrm{C}_{2}\left\{\mathrm{C}_{6} \mathrm{H}_{3}(3-n \mathrm{Pr})(2-\mathrm{O}-)\right\}_{4}\right]$-gem- anti- $\left\{\mathrm{TiCl}_{2}\left(\mathrm{OC}_{4} \mathrm{H}_{8}\right)\right\}_{2}{ }^{-1} / 2\left[\mathrm{C}_{2}\left\{\mathrm{C}_{6} \mathrm{H}_{3}(3-\right.\right.$ $\left.\left.\left.{ }^{n} \mathrm{Pr}\right)(2-\mathrm{O}-)\right\}_{4}\right]_{2} \mathrm{Ti}_{2}$ cocrystallite, hemitoluene solvate
Formula: $\quad \mathrm{C}_{87.5} \mathrm{H}_{100} \mathrm{Cl}_{4} \mathrm{O}_{10} \mathrm{Ti}_{3}\left(\mathrm{C}_{46} \mathrm{H}_{56} \mathrm{Cl}_{4} \mathrm{O}_{6} \mathrm{Ti}_{2}{ }^{\circ} 0.5 \mathrm{C}_{76} \mathrm{H}_{80} \mathrm{O}_{8} \mathrm{Ti}_{2}{ }^{\bullet}{ }^{0} .5 \mathrm{C}_{7} \mathrm{H}_{8}\right)$

Figure 1. Perspective view of the $\left[\left\{\mathrm{C}_{2}\left(\mathrm{C}_{6} \mathrm{H}_{3}{ }^{n} \mathrm{Pr}\{\mathrm{O}-\}\right)_{4}\right\}\left\{\mathrm{TiCl}_{2}\left(\mathrm{OC}_{4} \mathrm{H}_{8}\right)\right\}_{2}\right]$ molecule showing the atom labelling scheme. Non-hydrogen atoms are represented by Gaussian ellipsoids at the $\mathbf{2 0 \%}$ probability level. Hydrogen atoms are not shown.

Figure 2. Perspective view of the $\left[\left\{\mathrm{C}_{2}\left(\mathrm{C}_{6} \mathrm{H}_{3}{ }^{n} \mathrm{Pr}\{\mathrm{O}-\}\right)_{4}\right\}_{2} \mathrm{Ti}_{2}\right]$ molecule showing the atom labelling scheme. Primed atoms are related to unprimed ones via the crystallographic inversion center ( $0,1 / 2,1 / 2$ ) midway between the Ti 3 and Ti3' atoms.

Figure 8. Illustration of the disposition of adjacent [ $\mathrm{C}_{2}\left(\mathrm{C}_{6} \mathrm{H}_{3}{ }^{n} \mathrm{Pr}\{\mathrm{O}\right.$ $\left.\left.\}_{4}\right\}\left\{\mathrm{TiCl}_{2}\left(\mathrm{OC}_{4} \mathrm{H}_{8}\right)\right\}_{2}\right]$ (left and right of diagram) and $\left[\left\{\mathrm{C}_{2}\left(\mathrm{C}_{6} \mathrm{H}_{3}{ }^{n} \mathrm{Pr}\{\mathrm{O}-\right.\right.\right.$ $\}_{4} \int_{2} \mathrm{Ti}_{2}$ ] (center) molecules. The crystallographic asymmetric unit contains one full $\left[\left\{\mathrm{C}_{2}\left(\mathrm{C}_{6} \mathrm{H}_{3}{ }^{n} \mathrm{Pr}\{\mathrm{O}-\}\right)_{4}\right\}\left\{\mathrm{TiCl}_{2}\left(\mathrm{OC}_{4} \mathrm{H}_{8}\right)\right\}_{2}\right]$ molecule and half of a $\left[\left\{\mathrm{C}_{2}\left(\mathrm{C}_{6} \mathrm{H}_{3}{ }^{n} \mathrm{Pr}\{\mathrm{O}-\}\right)_{4}\right\}_{2} \mathrm{Ti}_{2}\right]$ molecule, thus inversion about the ( 0 , $1 / 2,1 / 2$ ) center (as indicated by the primed atoms) generates the full molecules as shown.

${ }^{\boldsymbol{b}}$ Programs for diffractometer operation, data collection, data reduction and absorption correction were those supplied by Bruker.
${ }^{c}$ Beurskens, P. T.; Beurskens, G.; Bosman, W. P.; de Gelder, R.; Garcia Granda, S.; Gould, R. O.; Israel, R.; Smits, J. M. M. (1996). The DIRDIF-96 program system. Crystallography Laboratory, University of Nijmegen, The Netherlands.
${ }^{d}$ Sheldrick, G. M. SHELXL-93. Program for crystal structure determination. University of Göttingen, Germany, 1993. Refinement on $F_{0}{ }^{2}$ for all reflections (all of these having $F_{0}^{2} \geq-3 \sigma\left(F_{0}^{2}\right)$ ). Weighted $R$-factors $w R_{2}$ and all goodnesses of fit $S$ are based on $F_{0}^{2}$; conventional $R$-factors $R_{1}$ are based on $F_{0}$, with $F_{0}$ set to zero for negative $F_{0}^{2}$. The observed criterion of $F_{0}^{2}>2 \sigma\left(F_{0}^{2}\right)$ is used only for calculating $R_{1}$, and is not relevant to the choice of reflections for refinement. $R$-factors based on $F_{0}{ }^{2}$ are statistically about twice as large as those based on $F_{0}$, and $R$-factors based on ALL data will be even larger.
e $S=\left[\Sigma w\left(F_{0}^{2}-F_{c}^{2}\right)^{2 /(n-p)}\right]^{1 / 2}(n=$ number of data; $p=$ number of parameters varied; $w$ $=\left[\sigma^{2}\left(F_{0}^{2}\right)+(0.0302 P)^{2}+\operatorname{FACT} 2 P\right]^{-1}$ where $\left.P=\left[\operatorname{Max}\left(F_{0}{ }^{2}, 0\right)+2 F_{c}^{2}\right] / 3\right)$.
$f_{R_{1}}=\Sigma \| F_{\mathrm{o}}\left|-\left|F_{\mathrm{c}}\right|\right| / \Sigma\left|F_{\mathrm{o}}\right| ; w R_{2}=\left[\Sigma w\left(F_{0}^{2}-F_{\mathrm{c}}^{2}\right)^{2} / \Sigma w\left(F_{0}^{4}\right)\right]^{1 / 2}$.

Table 2. Atomic Coordinates and Equivalent Isotropic Displacement Parameters
(a) atoms of $\left[\left(\mathrm{C}_{2}\left(\mathrm{C}_{6} \mathrm{H}_{3}{ }^{n} \mathrm{Pr}(\mathrm{O}-)_{4} /\left(\mathrm{TiCl}_{2}\left(\mathrm{OC}_{4} \mathrm{H}_{8}\right)\right)_{2}\right]\right.\right.$

Anisotropically-refined atoms are marked with an asterisk (*). The form of the anisotropic displacement parameter is: $\exp \left[-2 \pi^{2}\left(h^{2} a^{* 2} U_{11}+k^{2} b^{* 2} U_{22}+l^{2} c^{* 2} U_{33}+\right.\right.$ $\left.\left.2 k l b^{*} c^{*} U_{23}+2 h l a^{*} c^{*} U_{13}+2 h k a^{*} b^{*} U_{12}\right)\right]$. ${ }^{a}$ Refined with an occupancy factor of 0.5 .
${ }^{b}$ Refined with an occupancy factor of 0.6 . ${ }^{c}$ Refined with an occupancy factor of 0.4 .
${ }^{d}$ Refined with an occupancy factor of 0.7 . ${ }^{e}$ Refined with an occupancy factor of 0.3 .

Primed atoms are related to unprimed ones via the crystallographic inversion center ( 0 , $1 / 2,1 / 2$ ).

## A-6: Complex 32. $\left[\mathrm{C}_{38} \mathrm{H}_{40} \mathrm{O}_{4}\right]_{2} \mathrm{Ti}_{2}$

- Chapter 3 -

## XCL Code: JMS0029

Date: 9 April 2001
Compound: $\quad\left[\mathrm{C}_{2}\left\{\mathrm{C}_{6} \mathrm{H}_{3}\left(3-{ }^{-n} \mathrm{Pr}\right)(2-\mathrm{O}-)\right]_{4}\right]_{2} \mathrm{Ti}_{2} \cdot \mathrm{PhMe}$
Formula: $\quad \mathrm{C}_{83} \mathrm{H}_{88} \mathrm{O}_{8} \mathrm{Ti}_{2}\left(\mathrm{C}_{76} \mathrm{H}_{80} \mathrm{O}_{8} \mathrm{Ti}_{2}{ }^{\circ} \mathrm{C}_{7} \mathrm{H}_{8}\right)$

Figure 1. Perspective view of the $\left[\left\{\mathrm{C}_{2}\left(\mathrm{C}_{6} \mathrm{H}_{3}{ }^{n} \mathrm{Pr}\{\mathrm{O}-\}\right)_{4}\right\}_{2} \mathrm{Ti}_{2}\right]$ molecule showing the atom labelling scheme. Non-hydrogen atoms are represented by Gaussian ellipsoids at the $20 \%$ probability level. Hydrogen atoms are not shown. Primed atoms are related to unprimed ones via the crystallographic inversion center ( $0,0,0$ ) midway between the Ti and $\mathrm{Ti}^{\prime}$ atoms.

${ }^{a}$ Obtained from least-squares refinement of 6150 centered reflections.
${ }^{b}$ Programs for diffractometer operation, data collection, data reduction and absorption correction were those supplied by Bruker.
cSheldrick, G. M. Acta Crystallogr. 1990, A46, 467-473.
${ }^{d}$ Sheldrick, G. M. SHELXL-93. Program for crystal structure determination. University of Göttingen, Germany, 1993. Refinement on $F_{0}{ }^{2}$ for all reflections (all of these having $F_{0}^{2} \geq-3 \sigma\left(F_{0}^{2}\right)$ ). Weighted $R$-factors $w R_{2}$ and all goodnesses of fit $S$ are based on $F_{0}^{2}$; conventional $R$-factors $R_{1}$ are based on $F_{0}$, with $F_{0}$ set to zero for negative $F_{0}{ }^{2}$. The observed criterion of $F_{0}^{2}>2 \sigma\left(F_{0}^{2}\right)$ is used only for calculating $R_{1}$, and is not relevant to the choice of reflections for refinement. $R$-factors based on $F_{0}{ }^{2}$ are statistically about twice as large as those based on $F_{0}$, and $R$-factors based on ALL data will be even larger.

$$
\begin{aligned}
e S & =\left[\Sigma w\left(F_{\mathrm{o}}^{2}-F_{\mathrm{c}^{2}}^{2}\right)^{2} /(n-p)\right]^{1 / 2}(n=\text { number of data; } p=\text { number of parameters varied; } w \\
& \left.=\left[\sigma^{2}\left(F_{0}^{2}\right)+(0.0730 P)^{2}+2.2511 P\right]^{-1} \text { where } P=\left[\operatorname{Max}\left(F_{\mathrm{o}}^{2}, 0\right)+2 F_{\mathrm{c}}^{2}\right] / 3\right) \\
f_{R_{1}} & =\Sigma| | F_{\mathrm{o}}\left|-\left|F_{\mathrm{c}}\right|\right| \Sigma\left|F_{\mathrm{o}}\right| ; w R_{2}=\left[\Sigma w\left(F_{\mathrm{o}}^{2}-F_{\mathrm{c}^{2}}^{2}\right)^{2} / \Sigma w\left(F_{\mathrm{o}}^{4}\right)\right]^{1 / 2} .
\end{aligned}
$$

## A-7 Complex 31. $\left[\mathrm{C}_{38} \mathrm{H}_{40} \mathrm{O}_{4}\right]$-vic-anti- $\left\{\mathrm{TiCl}_{\mathbf{2}}(\mathrm{thf})\right\}_{2}$

- Chapter 3 -

XCL Code: JMS9922
Date: 3 April 2001
Compound: $\left\{\mathrm{C}_{2}\left\{\mathrm{C}_{6} \mathrm{H}_{3}(3-n \mathrm{Pr})(2-\mathrm{O}-)\right\}_{4}\right]$-vic-anti- $\left\{\mathrm{TiCl}_{2}\left(\mathrm{OC}_{4} \mathrm{H}_{8}\right)\right\}_{2}$
Formula: $\quad \mathrm{C}_{46} \mathrm{H}_{56} \mathrm{Cl}_{4} \mathrm{O}_{6} \mathrm{Ti}_{2}$

Figure 1. Perspective view of the $\left[\left\{\mathrm{C}_{2}\left(\mathrm{C}_{6} \mathrm{H}_{3}{ }^{n} \mathrm{PrO}\right)_{4}\right\}\left\{\mathrm{TiCl}_{2}\left(\mathrm{OC}_{4} \mathrm{H}_{8}\right)\right]_{2}\right]$ molecule showing the atom labelling scheme. Non-hydrogen atoms are represented by Gaussian ellipsoids at the $20 \%$ probability level. Hydrogen atoms are not shown.

full-matrix least-squares on $F^{2}$ (SHELXL-93d)
SADABS
0.9077-0.5769
$9524\left[F_{0}^{2} \geq-3 \sigma\left(F_{0}^{2}\right)\right] / 6^{e} / 521$
$0.951\left[F_{0}^{2} \geq-3 \sigma\left(F_{0}^{2}\right)\right]$
${ }^{a}$ Obtained from least-squares refinement of 4407 centered reflections.
${ }^{b}$ Programs for diffractometer operation, data collection, data reduction and absorption correction were those supplied by Bruker.
${ }^{c}$ Sheldrick, G. M. Acta Crystallogr. 1990, A46, 467-473.
${ }^{d}$ Sheldrick, G. M. SHELXL-93. Program for crystal structure determination. University of Göttingen, Germany, 1993. Refinement on $F_{0}{ }^{2}$ for all reflections (all of these having $F_{0}^{2} \geq-3 \sigma\left(F_{0}^{2}\right)$ ). Weighted $R$-factors $w R_{2}$ and all goodnesses of fit $S$ are based on $F_{0}{ }^{2}$; conventional $R$-factors $R_{1}$ are based on $F_{0}$, with $F_{0}$ set to zero for negative $F_{0}^{2}$. The observed criterion of $F_{0}^{2}>2 \sigma\left(F_{0}^{2}\right)$ is used only for calculating $R_{1}$, and is not relevant to the choice of reflections for refinement. $R$-factors based on $F_{0}{ }^{2}$ are statistically about twice as large as those based on $F_{0}$, and $R$-factors based on ALL data will be even larger.
${ }^{e}$ An idealized geometry was imposed upon the disordered tetrahydrofuran ligand through use of the following restraints: $\mathrm{d}(\mathrm{C} 52 \mathrm{~A}-\mathrm{C} 53 \mathrm{~A})=\mathrm{d}(\mathrm{C} 53 \mathrm{~A}-\mathrm{C} 54 \mathrm{~A})=\mathrm{d}(\mathrm{C} 52 \mathrm{~B}-\mathrm{C} 53 \mathrm{~B})$ $=\mathrm{d}(\mathrm{C} 53 \mathrm{~B}-\mathrm{C} 54 \mathrm{~B})=1.54 \AA ; \mathrm{d}(\mathrm{C} 52 \mathrm{~A} \cdots \mathrm{C} 54 \mathrm{~A})=\mathrm{d}(\mathrm{C} 52 \mathrm{~A} \cdots \mathrm{C} 54 \mathrm{~A})=2.51 \AA$.
$f_{S}=\left[\Sigma w\left(F_{0}^{2}-F_{\mathrm{c}}^{2}\right)^{2 /(n-p)}\right]^{1 / 2}(n=$ number of data; $p=$ number of parameters varied; $w$ $=\left[\sigma^{2}\left(F_{0}^{2}\right)+(0.1006 P)^{2}\right]^{-1}$ where $\left.P=\left[\operatorname{Max}\left(F_{0}^{2}, 0\right)+2 F_{c}^{2}\right] / 3\right)$.
$g_{R_{1}}=\Sigma| | F_{0}\left|-\left|F_{\mathrm{c}}\right|\right| \Sigma\left|F_{\mathrm{o}}\right| ; w R_{2}=\left[\Sigma w\left(F_{0}^{2}-F_{c^{2}}^{2}\right)^{2} / \Sigma w\left(F_{0}^{4}\right)\right]^{1 / 2}$.

Anisotropically-refined atoms are marked with an asterisk (*). The form of the anisotropic displacement parameter is: $\exp \left[-2 \pi^{2}\left(h^{2} a^{* 2} U_{11}+k^{2} b^{* 2} U_{22}+l^{2} c^{* 2} U_{33}+\right.\right.$ $\left.2 k l b^{*} c^{*} U_{23}+2 h l a^{*} c^{*} U_{13}+2 h k a^{*} b^{*} U_{12}\right)$ ]. ${ }^{a}$ Refined with an occupancy factor of 0.5 .

## A-8: Complex 33a. [ $\left.\mathrm{C}_{38} \mathrm{H}_{40} \mathrm{O}_{4}\right]$-gem-anti-\{TiBr $\mathbf{2}_{2}($ thf $\left.)\right\}_{2}$

- Chapter 3 -

## XCL Code: JMS0010

Date: 12 April 2000
Compound: $\left[\mathrm{C}_{2}\left\{\left.\mathrm{C}_{6} \mathrm{H}_{3}(3-n \mathrm{Pr})(2-\mathrm{O}-)\right|_{4}\right]\left\{\mathrm{TiBr}_{2}\left(\mathrm{OC}_{4} \mathrm{H}_{8}\right)\right\}_{2} \cdot \mathrm{PhMe}\right.$
Formula: $\mathrm{C}_{53} \mathrm{H}_{64} \mathrm{Br}_{4} \mathrm{O}_{6} \mathrm{Ti}_{2}\left(\mathrm{C}_{46} \mathrm{H}_{56} \mathrm{Br}_{4} \mathrm{O}_{6} \mathrm{Ti}_{2} \cdot \mathrm{C}_{7} \mathrm{H}_{8}\right)$

Figure 1. Perspective view of the $\left[\left(\mathrm{C}_{2}\left\{\mathrm{C}_{6} \mathrm{H}_{3}\left({ }^{(n \mathrm{Pr})}\left(\mathrm{O}_{-}\right)\right]_{4}\right)\left\{\left.\mathrm{TiBr}_{2}\left(\mathrm{OC}_{4} \mathrm{H}_{8}\right)\right|_{2}\right]\right.\right.$ molecule showing the atom labelling scheme. Non-hydrogen atoms are represented by Gaussian ellipsoids at the 20\% probability level. Hydrogen atoms are not shown.

${ }^{a}$ Obtained from least-squares refinement of 4774 centered reflections.
${ }^{b}$ Programs for diffractometer operation, data collection, data reduction and absorption correction were those supplied by Bruker.
${ }^{c}$ Sheldrick, G. M. Acta Crystallogr. 1990, A46, 467-473.
${ }^{d}$ Sheldrick, G. M. SHELXL-93. Program for crystal structure determination. University of Göttingen, Germany, 1993. Refinement on $F_{0}^{2}$ for all reflections (all of these having $F_{0}^{2} \geq-3 \sigma\left(F_{0}^{2}\right)$ ). Weighted $R$-factors $w R_{2}$ and all goodnesses of fit $S$ are based on $F_{0}{ }^{2}$; conventional $R$-factors $R_{1}$ are based on $F_{0}$, with $F_{0}$ set to zero for negative $F_{0}{ }^{2}$. The observed criterion of $F_{0}^{2}>2 \sigma\left(F_{0}^{2}\right)$ is used only for calculating $R_{1}$, and is not relevant to the choice of reflections for refinement. $R$-factors based on $F_{0}{ }^{2}$ are statistically about twice as large as those based on $F_{0}$, and $R$-factors based on ALL data will be even larger.
e $S=\left[\Sigma w\left(F_{0}^{2}-F_{c}^{2}\right)^{2} /(n-p)\right]^{1 / 2}(n=$ number of data; $p=$ number of parameters varied; $w$ $=\left[\sigma^{2}\left(F_{0}^{2}\right)+(0.0270 P)^{2}\right]^{-1}$ where $\left.P=\left[\operatorname{Max}\left(F_{0}^{2}, 0\right)+2 F_{c}^{2}\right] / 3\right)$.
$f_{R_{1}}=\Sigma| | F_{0}\left|-\left|F_{\mathrm{c}} \||\Sigma| F_{0}\right| ; w R_{2}=\left[\Sigma w\left(F_{0}^{2}-F_{\mathrm{c}^{2}}\right)^{2} / \Sigma w\left(F_{0}^{4}\right)\right]^{1 / 2}\right.$.

## A-9: Complex 34. $\mathrm{C}_{38} \mathrm{H}_{40} \mathrm{O}_{\mathbf{4}}{ }^{\circ}(\mathbf{C p T i C l})_{2}$

- Chapter 3 -

XCL Code: JMS9917
Date: 27 April 2001
Compound: $\quad\left[\left\{\mathrm{C}_{2}\left(\mathrm{C}_{6} \mathrm{H}_{3}{ }^{n} \mathrm{Pr}\{\mathrm{O}-)_{4}\right\}(\mathrm{CpTiCl})_{2}\right] \cdot 2 \mathrm{PhMe}\right.$
Formula: $\quad \mathrm{C}_{62} \mathrm{H}_{66} \mathrm{Cl}_{2} \mathrm{O}_{4} \mathrm{Ti}_{2}\left(\mathrm{C}_{48} \mathrm{H}_{50} \mathrm{Cl}_{2} \mathrm{O}_{4} \mathrm{Ti}_{2} \cdot 2 \mathrm{C}_{7} \mathrm{H}_{8}\right)$

Figure 1. Perspective view of the $\left[\left\{\mathrm{C}_{2}\left(\mathrm{C}_{6} \mathrm{H}_{3}{ }^{n} \mathrm{Pr}\{\mathrm{O}-\}_{4}\right\}(\mathrm{CpTiCl})_{2}\right]\right.$ molecule/ion showing the atom labelling scheme. Non-hydrogen atoms are represented by Gaussian ellipsoids at the $\mathbf{2 0 \%}$ probability level. Hydrogen atoms are not shown. Primed atoms are related to unprimed ones via the crystallographic inversion center ( $0,0,1 / 2$ ) at the midpoint of the $\mathrm{Cl}-\mathrm{Cl}$ ' bond.

${ }^{a}$ Obtained from least-squares refinement of 4097 centered reflections.
${ }^{b}$ Programs for diffractometer operation, data collection, data reduction and absorption correction were those supplied by Bruker.
${ }^{\text {cos }}$ Sheldrick, G. M. Acta Crystallogr. 1990, A46, 467-473.
${ }^{d}$ Sheldrick, G. M. SHELXL-93. Program for crystal structure determination. University of Göttingen, Germany, 1993. Refinement on $F_{0}{ }^{2}$ for all reflections (all of these having $F_{0}^{2} \geq-3 \sigma\left(F_{0}^{2}\right)$ ). Weighted $R$-factors $w R_{2}$ and all goodnesses of fit $S$ are based on $F_{0}^{2}$; conventional $R$-factors $R_{1}$ are based on $F_{0}$, with $F_{0}$ set to zero for negative $F_{0}{ }^{2}$. The observed criterion of $F_{0}^{2}>2 \sigma\left(F_{0}^{2}\right)$ is used only for calculating $R_{1}$, and is not relevant to the choice of reflections for refinement. $R$-factors based on $F_{0}{ }^{2}$ are statistically about twice as large as those based on $F_{0}$, and $R$-factors based on ALL data will be even larger.
${ }^{e}$ An idealized geometry was imposed on the disordered $n$-propyl groups of the $\mathrm{C}_{2}\left(\mathrm{C}_{6} \mathrm{H}_{3}{ }^{n} \mathrm{Pr}\{\mathrm{O}-\}\right) 4$ ligand through use of the following distance conditions: $\mathrm{d}(\mathrm{Cl} 17-\mathrm{C} 18 \mathrm{~A})=\mathrm{d}(\mathrm{C} 18 \mathrm{~A}-\mathrm{Cl} 9 \mathrm{~A})=\mathrm{d}(\mathrm{C17}-\mathrm{C} 18 \mathrm{~B})=\mathrm{d}(\mathrm{Cl} 8 \mathrm{~B}-\mathrm{Cl} 9 \mathrm{~B})=\mathrm{d}(\mathrm{C} 27-\mathrm{C} 28 \mathrm{~A})$ $=\mathrm{d}(\mathrm{C} 28 \mathrm{~A}-\mathrm{C} 29 \mathrm{~A})=\mathrm{d}(\mathrm{C} 27-\mathrm{C} 28 \mathrm{~B})=\mathrm{d}(\mathrm{C} 28 \mathrm{~B}-\mathrm{C} 29 \mathrm{~B})=1.54 \AA ; \mathrm{d}(\mathrm{C} 17 \cdots \mathrm{C} 19 \mathrm{~A})=$ $\mathrm{d}(\mathrm{C} 17 \cdots \mathrm{C} 19 \mathrm{~B})=\mathrm{d}(\mathrm{C} 27 \cdots \mathrm{C} 29 \mathrm{~A})=\mathrm{d}(\mathrm{C} 27 \cdots \mathrm{C} 29 \mathrm{~B})=2.52 \AA$. The ring carbons of one of the solvent toluene molecules (containing C21S through C26S, and disordered about the crystallographic inversion center ( $0,1 / 2,1 / 2$ ) ) were refined as an idealized hexagon with a bond distance of $1.39 \AA$, and the geometry of the methyl carbon was also idealized $(\mathrm{d}(\mathrm{C} 20 \mathrm{~S}-\mathrm{C} 21 \mathrm{~S})=1.54 \AA ; \mathrm{d}(\mathrm{C} 20 \mathrm{~S} \cdots \mathrm{C} 22 \mathrm{~S})=\mathrm{d}(\mathrm{C} 20 \mathrm{~S} \cdots \mathrm{C} 26 \mathrm{~S})=2.54$ Å).
 $=\left[\sigma^{2}\left(F_{0}^{2}\right)+(0.1420 P)^{2}\right]^{-1}$ where $\left.P=\left[\operatorname{Max}\left(F_{0}^{2}, 0\right)+2 F_{\mathrm{c}}^{2}\right] / 3\right)$.
$s R_{1}=\Sigma| | F_{0}\left|-\left|F_{c}\right|\right| \Sigma\left|F_{0}\right| ; w R_{2}=\left[\Sigma w\left(F_{0}^{2}-F_{c}^{2}\right)^{\left.2 / \Sigma w\left(F_{0}^{4}\right)\right]^{1 / 2} .}\right.$

${ }^{d}$ Sheldrick, G. M. SHELXL-93. Program for crystal structure determination. University of Göttingen, Germany, 1993. Refinement on $F_{0}{ }^{2}$ for all reflections (all of these having $F_{0}^{2} \geq-3 \sigma\left(F_{0}^{2}\right)$ ). Weighted $R$-factors $w R_{2}$ and all goodnesses of fit $S$ are based on $F_{0}{ }^{2}$; conventional $R$-factors $R_{1}$ are based on $F_{0}$, with $F_{0}$ set to zero for negative $F_{0}^{2}$. The observed criterion of $F_{0}^{2}>2 \sigma\left(F_{0}^{2}\right)$ is used only for calculating $R_{\mathrm{l}}$, and is not relevant to the choice of reflections for refinement. $R$-factors based on $F_{0}{ }^{2}$ are statistically about twice as large as those based on $F_{0}$, and $R$-factors based on ALL data will be even larger.
e $S=\left[\Sigma w\left(F_{0}^{2}-F_{\mathrm{c}}^{2}\right)^{2 /(n-p)}\right]^{1 / 2}(n=$ number of data; $p=$ number of parameters varied; $w$ $=\left[\sigma^{2}\left(F_{0}^{2}\right)+(0.0888 P)^{2}\right]^{-1}$ where $\left.P=\left[\operatorname{Max}\left(F_{0}^{2}, 0\right)+2 F_{c}^{2}\right] / 3\right)$.
$f_{R_{1}}=\Sigma| | F_{0}\left|-\left|F_{c}\right|\right| \Sigma\left|F_{0}\right| ; w R_{2}=\left[\Sigma w\left(F_{0}^{2}-F_{c}^{2}\right)^{2 / \Sigma} w\left(F_{0}^{4}\right)\right]^{1 / 2}$.

${ }^{a}$ Obtained from least-squares refinement of 5991 centered reflections.
${ }^{\boldsymbol{b}}$ Programs for diffractometer operation, data collection, data reduction and absorption correction were those supplied by Bruker.
cSheldrick, G. M. Acta Crystallogr. 1990, A46, 467-473.
${ }^{d}$ Sheldrick, G. M. SHELXL-93. Program for crystal structure determination. University of Göttingen, Germany, 1993. Refinement on $F_{0}{ }^{2}$ for all reflections (all of these having $F_{0}^{2} \geq-3 \sigma\left(F_{0}^{2}\right)$ ). Weighted $R$-factors $w R_{2}$ and all goodnesses of fit $S$ are based on $F_{0}{ }^{2}$; conventional $R$-factors $R_{1}$ are based on $F_{0}$, with $F_{0}$ set to zero for negative $F_{0}^{2}$. The observed criterion of $F_{0}^{2}>2 \sigma\left(F_{0}^{2}\right)$ is used only for calculating $R_{1}$, and is not relevant to the choice of reflections for refinement. $R$-factors based on $F_{0}{ }^{2}$ are statistically about twice as large as those based on $F_{0}$, and $R$-factors based on ALL data will be even larger.
$e S=\left[\Sigma w\left(F_{0}^{2}-F_{\mathrm{c}}{ }^{2}\right)^{2} /(n-p)\right]^{1 / 2}(n=$ number of data; $p=$ number of parameters varied; $w$ $=\left[\sigma^{2}\left(F_{0}^{2}\right)+(0.0920 P)^{2}\right]^{-1}$ where $\left.P=\left[\operatorname{Max}\left(F_{0}^{2}, 0\right)+2 F_{c}^{2}\right] / 3\right)$.
$f_{R_{1}}=\Sigma\left\|\left|F_{0}\right|-\left|F_{\mathrm{c}} \| / \Sigma\right| F_{0} \mid ; w R_{2}=\left[\Sigma w\left(F_{0}^{2}-F_{c^{2}}\right)^{2} / \Sigma w\left(F_{0}^{4}\right)\right]^{1 / 2}\right.$.

## A-12: Complex 39. $\mathrm{C}_{38} \mathrm{H}_{40} \mathrm{O}_{4}[\mathrm{Al}($ thf $)]\left[\mathrm{AlCl}_{2}\right]$

- Chapter 3-

XCL Code: JMS0050
Date: 3 June 2001
Compound: $\quad\left[\left\{\mathrm{C}_{2}\left(\mathrm{C}_{6} \mathrm{H}_{3}{ }^{n} \mathrm{Pr}\{\mathrm{O}-\}\right)_{4}\right\}\left\{\mathrm{Al}\left(\mathrm{OC}_{4} \mathrm{H}_{8}\right)\right\}\left(\mathrm{AlCl}_{2}\right)\right]$
Formula: $\quad \mathrm{C}_{42} \mathrm{H}_{48} \mathrm{Al}_{2} \mathrm{Cl}_{2} \mathrm{O}_{5}$

Figure 1. Perspective view of the $\left[\left\{\mathrm{C}_{2}\left(\mathrm{C}_{6} \mathrm{H}_{3}{ }^{n} \operatorname{Pr}(\mathrm{O}-\}\right)_{4}\right\}\left\{\mathrm{Al}\left(\mathrm{OC}_{4} \mathrm{H}_{8}\right)\right\}\left(\mathrm{AlCl}_{2}\right)\right]$ molecule showing the atom labelling scheme. Non-hydrogen atoms are represented by Gaussian ellipsoids at the $20 \%$ probability level. Hydrogen atoms are not shown.

$1.031\left[F_{0}{ }^{2} \geq-3 \sigma\left(F_{0}{ }^{2}\right)\right]$
${ }^{a}$ Obtained from least-squares refinement of 5589 centered reflections.
${ }^{b}$ Programs for diffractometer operation, data collection, data reduction and absorption correction were those supplied by Bruker.
${ }^{\text {c Sheldrick, G. M. Acta Crystallogr. 1990, A46, 467-473. }}$
${ }^{d}$ Sheldrick, G. M. SHELXL-93. Program for crystal structure determination. University of Göttingen, Germany, 1993. Refinement on $F_{0}{ }^{2}$ for all reflections (all of these having $F_{0}^{2} \geq-3 \sigma\left(F_{0}^{2}\right)$ ). Weighted $R$-factors $w R_{2}$ and all goodnesses of fit $S$ are based on $F_{0}{ }^{2}$; conventional $R$-factors $R_{1}$ are based on $F_{0}$, with $F_{0}$ set to zero for negative $F_{0}{ }^{2}$. The observed criterion of $F_{0}{ }^{2}>2 \sigma\left(F_{0}^{2}\right)$ is used only for calculating $R_{1}$, and is not relevant to the choice of reflections for refinement. $R$-factors based on $F_{0}{ }^{2}$ are statistically about twice as large as those based on $F_{\mathrm{O}}$, and $R$-factors based on ALL data will be even larger.

$$
\begin{aligned}
e S & =\left[\Sigma w\left(F_{0}^{2}-F_{\mathrm{c}}^{2}\right)^{2 /(n-p)}\right)^{1 / 2}(n=\text { number of data; } p=\text { number of parameters varied; } w \\
& \left.=\left[\sigma^{2}\left(F_{0}^{2}\right)+(0.0759 P)^{2}+2.2850 P\right]^{-1} \text { where } P=\left[\operatorname{Max}\left(F_{0}^{2}, 0\right)+2 F_{\mathrm{c}}^{2}\right] / 3\right) . \\
f_{R_{1}} & =\Sigma\left\|F_{0}\left|-\left|F_{\mathrm{c}} \| / \Sigma\right| F_{0}\right| ; w R_{2}=\left[\Sigma w\left(F_{0}^{2}-F_{\mathrm{c}}^{2}\right)^{2} / \Sigma w\left(F_{0}^{4}\right)\right]^{1 / 2} .\right.
\end{aligned}
$$

## A-13: Complex 41. $\mathrm{C}_{38} \mathrm{H}_{40} \mathrm{O}_{4} \bullet[\mathrm{MgCl}($ thf $)] \bullet[\mathrm{Mg}($ thf $)] \cdot[$ AIEt2]

- Chapter 3 -

## XCL Code: JMS0046

Date: 13 February 2001
Compound: $\left[\left(\mathrm{C}_{2}\left\{\mathrm{C}_{6} \mathrm{H}_{3}\left({ }^{\left(\mathrm{PPr}^{2}\right) \mathrm{O}}\right\}_{4}\right)\left\{\mathrm{Mg}\left(\mathrm{OC}_{4} \mathrm{H}_{8}\right)\right\}\left(\mathrm{MgCl}_{5}\left(\mathrm{OC}_{4} \mathrm{H}_{8}\right)\right\}\left(\mathrm{AlEt}_{2}\right)\right] \cdot \mathrm{PhMe}\right.$ Formula: $\quad \mathrm{C}_{57} \mathrm{H}_{74} \mathrm{AlClMg}_{2} \mathrm{O}_{6}\left(\mathrm{C}_{50} \mathrm{H}_{66} \mathrm{AlClMg}_{2} \mathrm{O}_{6}{ }^{\circ} \mathrm{C}_{7} \mathrm{H}_{8}\right)$

Figure 1. Perspective view of the $\left[\left(\mathrm{C}_{2}\left\{\mathrm{C}_{6} \mathrm{H}_{3}\left({ }^{( } \mathrm{Pr}\right) \mathrm{O}\right\}_{4}\right)\left(\mathrm{Mg}\left(\mathrm{OC}_{4} \mathrm{H}_{8}\right)\right\}\right.$ $\left.\left\{\mathrm{MgCl}\left(\mathrm{OC}_{4} \mathrm{H}_{8}\right)\right\}\left(\mathrm{AlEt}_{2}\right)\right]$ molecule showing the atom labelling scheme. Non-hydrogen atoms are represented by Gaussian ellipsoids at the $\mathbf{2 0 \%}$ probability level. Hydrogen atoms are not shown.

0.9793-0.9238
$10857\left[F_{0}^{2} \geq-3 \sigma\left(F_{0}^{2}\right)\right] / 0 / 603$
$1.031\left[F_{0}{ }^{2} \geq-3 \sigma\left(F_{0}^{2}\right)\right]$
0.573 and -0.392 e $\AA^{-3}$
${ }^{a}$ Obtained from least-squares refinement of 4497 centered reflections.
${ }^{b}$ Programs for diffractometer operation, data collection, data reduction and absorption correction were those supplied by Bruker.
${ }^{c}$ Beurskens, P. T.; Beurskens, G.; Bosman, W. P.; de Gelder, R.; Garcia Granda, S.; Gould, R. O.; Israel, R.; Smits, J. M. M. (1996). The DIRDIF-96 program system. Crystallography Laboratory, University of Nijmegen, The Netherlands.
${ }^{d}$ Sheldrick, G. M. SHELXL-93. Program for crystal structure determination. University of Göttingen, Germany, 1993. Refinement on $F_{0}{ }^{2}$ for all reflections (all of these having $F_{0}^{2} \geq-3 \sigma\left(F_{0}^{2}\right)$ ). Weighted $R$-factors $w R_{2}$ and all goodnesses of fit $S$ are based on $F_{0}{ }^{2}$; conventional $R$-factors $R_{1}$ are based on $F_{0}$, with $F_{0}$ set to zero for negative $F_{0}{ }^{2}$. The observed criterion of $F_{0}^{2}>2 \sigma\left(F_{0}^{2}\right)$ is used only for calculating $R_{1}$, and is not relevant to the choice of reflections for refinement. $R$-factors based on $F_{0}{ }^{2}$ are statistically about twice as large as those based on $F_{\mathrm{o}}$, and $R$-factors based on ALL data will be even larger.
${ }^{e} S=\left[\Sigma w\left(F_{0}^{2}-F_{\mathrm{c}}^{2}\right)^{2 /(n-p)}\right]^{1 / 2}(n=$ number of data; $p=$ number of parameters varied; $w$ $=\left[\sigma^{2}\left(F_{0}^{2}\right)+(0.0578 P)^{2}+4.9804 P\right]^{-1}$ where $\left.P=\left[\operatorname{Max}\left(F_{0}^{2}, 0\right)+2 F_{c}^{2}\right] / 3\right)$.
$f R_{1}=\Sigma| | F_{\mathrm{o}}\left|-\left|F_{\mathrm{c}}\right|\right| \Sigma\left|F_{\mathrm{o}}\right| ; w R_{2}=\left[\Sigma w\left(F_{0}^{2}-F_{\mathrm{c}^{2}}^{2}\right)^{2} / \Sigma w\left(F_{\mathrm{o}}^{4}\right)\right]^{1 / 2}$.

Table 2. Atomic Coordinates and Equivalent Isotropic Displacement Parameters (a) atoms of $\left[\left(\mathrm{C}_{2}\left(\mathrm{C}_{6} \mathrm{H}_{3}\left({ }^{( }{ }^{\left.(\mathrm{Pr}) O)_{4}\right)} / \mathrm{Mg}\left(\mathrm{OC}_{4} \mathrm{H}_{8}\right) /\left(\mathrm{MgCl}\left(\mathrm{OC}_{4} \mathrm{H}_{8}\right) /\left(\mathrm{AlEt}_{2}\right)\right]\right.\right.\right.\right.$

Anisotropically-refined atoms are marked with an asterisk (*). The form of the anisotropic displacement parameter is: $\exp \left[-2 \pi^{2}\left(h^{2} a^{* 2} U_{11}+k^{2} b^{* 2} U_{22}+l^{2} c^{* 2} U_{33}+\right.\right.$ $\left.\left.2 k l b^{*} c^{*} U_{23}+2 h l a^{*} c^{*} U_{13}+2 h k a^{*} b^{*} U_{12}\right)\right]$. ${ }^{\text {R Refined with an occupancy factor of } 0.65 .}$
${ }^{b}$ Refined with an occupancy factor of 0.35 . ${ }^{c}$ Refined with an occupancy factor of 0.7 .
${ }^{d}$ Refined with an occupancy factor of 0.3 .

${ }^{\text {cosheldrick, G. M. Acta Crystallogr. 1990, A46, 467-473. }}$
${ }^{d}$ Sheldrick, G. M. SHELXL-93. Program for crystal structure determination. University of Göttingen, Germany, 1993. Refinement on $F_{0}{ }^{2}$ for all reflections (all of these having $F_{0}^{2} \geq-3 \sigma\left(F_{0}^{2}\right)$ ). Weighted $R$-factors $w R_{2}$ and all goodnesses of fit $S$ are based on $F_{0}{ }^{2}$; conventional $R$-factors $R_{1}$ are based on $F_{0}$, with $F_{0}$ set to zero for negative $F_{0}^{2}$. The observed criterion of $F_{0}^{2}>2 \sigma\left(F_{0}^{2}\right)$ is used only for calculating $R_{1}$, and is not relevant to the choice of reflections for refinement. $R$-factors based on $F_{0}{ }^{2}$ are statistically about twice as large as those based on $F_{0}$, and $R$-factors based on ALL data will be even larger.
eS $=\left[\Sigma w\left(F_{0}^{2}-F_{\mathrm{c}}^{2}\right)^{2} /(n-p)\right]^{1 / 2}(n=$ number of data; $p=$ number of parameters varied; $w$ $=\left[\sigma^{2}\left(F_{\mathrm{o}}^{2}\right)+(0.0836 P)^{2}+0.1586 P\right]^{-1}$ where $\left.P=\left[\operatorname{Max}\left(F_{\mathrm{o}}{ }^{2}, 0\right)+2 F_{\mathrm{c}}^{2}\right] / 3\right)$.
$f_{R_{1}}=\Sigma| | F_{\mathrm{o}}\left|-\left|F_{\mathrm{c}}\right|\right| \Sigma\left|F_{\mathrm{o}}\right| ; w R_{2}=\left[\Sigma w\left(F_{0}{ }^{2}-F_{\mathrm{c}}{ }^{2}\right)^{\left.2 / \Sigma w\left(F_{0}{ }^{4}\right)\right]^{1 / 2} .}\right.$

Table 6. Least-Square Plane Calculation and Selected Atom Deviations for O1-O2-03-04

| Plane | Coefficients ${ }^{\text {a }}$ |  | Defining Atoms with Deviations |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| $(\AA)^{b}$ |  |  |  |  |  |  |
| 1 | -0.098(8) | 19.421(2) 1.135(14) | 7.833(4) |  |  |  |
|  |  |  | O1 | 0.0022(9) | O 2 | -0.0022(9) |
|  |  |  | O3 | -0.0022(9) | O 4 | 0.0022(9) |
|  |  |  | Al1 | 0.1697(13) | Al2 | -0.672(2) |
|  |  |  | Mg | -0.1815(13) |  |  |

${ }^{a}$ Coefficients are for the form $a x+b y+c z=d$ where $x, y$ and $z$ are crystallographic coordinates.
bUnderlined atoms were not included in the definition of the plane.

## A-15: Complex 45. ([ $\left.\mathrm{C}_{38} \mathrm{H}_{40} \mathrm{O}_{4}\right](\mathrm{TiBn})(\mathrm{MgCl}(\text { (thf }))_{2}$

- Chapter 3 -

## PRELIMINARY STRUCTURE REPORT - NOT FOR PUBLICATION

XCL Code: JMS0036
Date: $\quad 1$ June 2001
Compound: $\quad\left[\left\{\mathrm{C}_{2}\left(\left.\mathrm{C}_{6} \mathrm{H}_{3}\right|^{n \mathrm{Pr}} \mid\{\mathrm{O}-)_{4}\right\}\left(\mathrm{TiCH}_{2} \mathrm{Ph}\right)\left(\mathrm{Mg}\left(\mathrm{OC}_{4} \mathrm{H}_{8}\right)(\mu-\mathrm{Cl})\right\}\right]_{2}{ }^{0} 0.5 \mathrm{PhMe}\right.$
Formula: $\quad \mathrm{C}_{101.5} \mathrm{H}_{114} \mathrm{Cl}_{2} \mathrm{Mg}_{2} \mathrm{O}_{10} \mathrm{Ti}_{2}\left(\mathrm{C}_{98} \mathrm{H}_{110} \mathrm{Cl}_{2} \mathrm{Mg}_{2} \mathrm{O}_{10} \mathrm{Ti}_{2}{ }^{\circ}{ }^{0} .5 \mathrm{C}_{7} \mathrm{H}_{8}\right)$

Figure 1. 'Framework' view of the $\left[\left\{\mathrm{C}_{2}\left(\mathrm{C}_{6} \mathrm{H}_{3}{ }^{[n \mathrm{Pr}}\right\}\{0\right.\right.$ $\left.\left.)_{4}\right)\left(\mathrm{TiCH}_{2} \mathrm{Ph}\right)\left(\mathrm{Mg}\left(\mathrm{OC}_{4} \mathrm{H}_{8}\right)(\mu-\mathrm{Cl})\right\}\right]_{2}$ molecule showing the atom labelling scheme. $\mathrm{Ti}, \mathrm{Cl}, \mathrm{Mg}$ and O atoms are represented by Gaussian ellipsoids at the $20 \%$ probability level; carbon thermal ellipsoids have been omitted, and hydrogen atom positions are not shown.

${ }^{a}$ Obtained from least-squares refinement of 4707 centered reflections.
${ }^{b}$ Programs for diffractometer operation, data collection, data reduction and absorption correction were those supplied by Bruker.
${ }^{c}$ Beurskens, P. T.; Beurskens, G.; Bosman, W. P.; de Gelder, R.; Garcia Granda, S.; Gould, R. O.; Israel, R.; Smits, J. M. M. (1996). The DIRDIF-96 program system. Crystallography Laboratory, University of Nijmegen, The Netherlands.
${ }^{d}$ Sheldrick, G. M. SHELXL-93. Program for crystal structure determination. University of Göttingen, Germany, 1993. Refinement on $F_{0}{ }^{2}$ for all reflections (all of these having $F_{0}^{2} \geq-3 \sigma\left(F_{0}^{2}\right)$ ). Weighted $R$-factors $w R_{2}$ and all goodnesses of fit $S$ are based on $F_{0}{ }^{2}$; conventional $R$-factors $R_{1}$ are based on $F_{0}$, with $F_{0}$ set to zero for negative $F_{0}^{2}$. The observed criterion of $F_{0}^{2}>2 \sigma\left(F_{0}^{2}\right)$ is used only for calculating $R_{1}$, and is not relevant to the choice of reflections for refinement. $R$-factors based on $F_{0}{ }^{2}$ are statistically about twice as large as those based on $F_{0}$, and $R$-factors based on ALL data will be even larger.
${ }^{e} S=\left[\Sigma w\left(F_{0}^{2}-F_{c^{2}}\right)^{2 /(n-p)}\right]^{1 / 2}(n=$ number of data; $p=$ number of parameters varied; $w$ $=\left[\sigma^{2}\left(F_{0}^{2}\right)+(0.2000 P)^{2}\right]^{-1}$ where $\left.P=\left[\operatorname{Max}\left(F_{0}^{2}, 0\right)+2 F_{c}^{2}\right] / 3\right)$.
$f_{R_{1}}=\Sigma| | F_{0}\left|-\left|F_{\mathrm{c}}\right|\right| \Sigma\left|F_{0}\right| ; w R_{2}=\left[\Sigma w\left(F_{0}^{2}-F_{\mathrm{c}}^{2}\right)^{2 / \Sigma w}\left(F_{0}^{4}\right)\right]^{1 / 2}$.

Anisotropically-refined atoms are marked with an asterisk (*). The form of the anisotropic displacement parameter is: $\exp \left[-2 \pi^{2}\left(h^{2} a^{* 2} U_{11}+k^{2} b^{* 2} U_{22}+l^{2} c^{* 2} U_{33}+\right.\right.$ $\left.\left.2 k l b^{*} c^{*} U_{23}+2 h l a^{*} c^{*} U_{13}+2 h k a^{*} b^{*} U_{12}\right)\right]$. ${ }^{\text {a Refined }}$ with an occupancy factor of 0.5 . ${ }^{b}$ The benzyl group rings were refined as an idealized hexagon $(\mathrm{d}(\mathrm{C}-\mathrm{C})=1.39 \AA)$; each set of ring carbons was refined with a common isotropic dispalcement parameter. ${ }^{\text {c The }}$ ring carbons of the solvent toluene molecule were refined as an idealized hexagon ( $\mathbf{d}(\mathbf{C}-\mathrm{C})=1.39 \AA$ ); all solvent toluene carbons were refined with an occupancy factor of 0.5 and with a common isotropic dispalcement parameter.

## A-16: Complex 46. $\left[\mathrm{C}_{38} \mathrm{H}_{40} \mathrm{O}_{4}\right](\mathrm{TiX})($ AlX'Et)

- Chapter 3 -

# PRELIMINARY STRUCTURE REPORT - NOT FOR PUBLICATION 

XCL Code: JMS0049
Date: 4 June 2001
Compound: $\quad\left[\left\{\mathrm{C}_{2}\left(\mathrm{C}_{6} \mathrm{H}_{3}{ }^{n} \mathrm{Pr}\{\mathrm{O}-\}\right)_{4}\right\}(\mathrm{TiX})(\mathrm{AlXEt})\right](\mathrm{X}=\mathrm{Cl}, 50 \%$; $\mathrm{Et}, 50 \%)$
Formula: $\quad \mathrm{C}_{42} \mathrm{H}_{50} \mathrm{AlClO}_{4} \mathrm{Ti}$

Figure 1. (See next page)
Illustration of the four possible permutations of $\left[\left\{\mathrm{C}_{2}\left(\mathrm{C}_{6} \mathrm{H}_{3} \boldsymbol{n} \operatorname{Pr}\{\mathrm{O}-\}\right)_{4}\right\}\right.$ ( TiX )(AIXEt)] ( $\mathrm{X}=\mathrm{Cl}$ or Et ) for one of the two crystallographicallyindependent molecules (molecule A) showing the atom labelling scheme. Non-hydrogen atoms are represented by Gaussian ellipsoids at the $20 \%$ probability level. Hydrogen atoms are not shown. Since the disordered Cl and Et groups are each refined with an occupancy factor of $50 \%$, each of these permutations is equally abundant. The second crystallographicallyindependent molecule (molecule B) is essentially identical aside from minor conformational differences involving the Et and ${ }^{n} \mathrm{Pr}$ groups, so will not be shown.

$\left[\left\{\mathrm{C}_{2}\left(\mathrm{C}_{6} \mathrm{H}_{3}{ }^{n} \mathrm{Pr}\{\mathrm{O}-\mid)_{4}\right\}(\mathrm{TiCl})(\mathrm{AICLEt})\right]\right.$

$\left[\left\{\mathrm{C}_{2}\left(\mathrm{C}_{6} \mathrm{H}_{3}{ }^{n} \mathrm{Pr}(\mathrm{O}-\mathrm{f})_{4}\right)(\mathrm{TiEt})(\mathrm{AIClEt})\right]\right.$

$\left[\left\{\mathrm{C}_{2}\left(\mathrm{C}_{6} \mathrm{H}_{3}{ }^{n} \mathrm{Pr}[\mathrm{O}-)_{4}\right\}(\mathrm{TiCl})\left(\mathrm{AlEt}_{2}\right)\right]\right.$

$\left[\left\{\mathrm{C}_{2}\left(\mathrm{C}_{6} \mathrm{H}_{3}{ }^{n \mathrm{Pr}}(\mathrm{O}-\mathrm{f})_{4}\right\}(\mathrm{TiEt})\left(\mathrm{AlEt}_{2}\right)\right]\right.$

largest difference peak and hole 1.385 and $-1.340 \mathrm{e}^{-3}$
${ }^{a}$ Obtained from least-squares refinement of 7624 centered reflections.
${ }^{b}$ Programs for diffractometer operation, data collection, data reduction and absorption correction were those supplied by Bruker.
${ }^{c}$ Sheldrick, G. M. Acta Crystallogr. 1990, A46, 467-473.
${ }^{\text {d }}$ Sheldrick, G. M. SHELXL-93. Program for crystal structure determination. University of Göttingen, Germany, 1993. Refinement on $F_{0}{ }^{2}$ for all reflections (all of these having $F_{0}^{2} \geq-3 \sigma\left(F_{0}^{2}\right)$ ). Weighted $R$-factors $w R_{2}$ and all goodnesses of fit $S$ are based on $F_{0}{ }^{2}$; conventional $R$-factors $R_{1}$ are based on $F_{0}$, with $F_{0}$ set to zero for negative $F_{0}^{2}$. The observed criterion of $F_{0}^{2}>2 \sigma\left(F_{0}^{2}\right)$ is used only for calculating $R_{1}$, and is not relevant to the choice of reflections for refinement. $R$-factors based on $F_{0}{ }^{2}$ are statistically about twice as large as those based on $F_{0}$, and $R$-factors based on ALL data will be even larger.
${ }^{e}$ An idealized geometry was imposed upon the disordered ethyl groups through application of the following restraints: $\mathrm{d}\left(\mathrm{Ti}-\mathrm{CH}_{2}\right)=2.15 \AA ; \mathrm{d}\left(\mathrm{Al}-\mathrm{CH}_{2}\right)=1.95 \AA$; $\mathrm{d}\left(\mathrm{CH}_{2}-\mathrm{CH}_{3}\right)=1.54 \AA ; \mathrm{d}\left(\mathrm{Ti} \cdots \mathrm{CH}_{3}\right)=3.03 \AA ; \mathrm{d}\left(\mathrm{Al} \cdots \mathrm{CH}_{3}\right)=2.90 \AA$.
$f S=\left[\Sigma w\left(F_{0}^{2}-F_{c^{2}}\right)^{2 /(n-p)}\right]^{1 / 2}(n=$ number of data; $p=$ number of parameters varied; $w$ $=\left[\sigma^{2}\left(F_{0}^{2}\right)+(0.1775 P)^{2}\right]^{-1}$ where $\left.P=\left[\operatorname{Max}\left(F_{0}^{2}, 0\right)+2 F_{c}^{2}\right] / 3\right)$.
$g R_{1}=\Sigma| | F_{\mathrm{o}}\left|-\left|F_{\mathrm{c}}\right|\right| \Sigma\left|F_{\mathrm{o}}\right| ; w R_{2}=\left[\Sigma w\left(F_{0}^{2}-F_{\mathrm{c}^{2}}\right)^{2} / \Sigma w\left(F_{\mathrm{o}}^{4}\right)\right]^{1 / 2}$.

Anisotropically-refined atoms are marked with an asterisk $\left(^{*}\right)$. The form of the anisotropic displacement parameter is: $\exp \left[-2 \pi^{2}\left(h^{2} a^{* 2} U_{11}+k^{2} b^{* 2} U_{22}+l^{2} c^{* 2} U_{33}+\right.\right.$ $\left.\left.2 k l b^{*} c^{*} U_{23}+2 h l a^{*} c^{*} U_{13}+2 h k a^{*} b^{*} U_{12}\right)\right]$. ${ }^{a}$ Refined with an occupancy factor of 0.5 . ${ }^{b}$ Atoms of the disordered ethyl groups of both independent molecules were refined with a common isotropic displacement parameter.

## A-17: Complex 47. $\left[\left\{E-\mathrm{C}_{2}\left(\mathrm{C}_{6} \mathrm{H}_{4}-\mathbf{2 - O}-\right)_{2}\left(\mathrm{C}_{6} \mathrm{H}_{4}-\mathbf{2 - O M e}\right)_{2}\right\} \mathrm{AlEt}\right]$

- Chapter 4 -

## XCL Code: JMS0051

Date:
6 April 2001
Compound: [ $\left.\left\{\mathrm{C}_{2}\left(\mathrm{C}_{6} \mathrm{H}_{4}-2-\mathrm{O}-\right)_{2}\left(\mathrm{C}_{6} \mathrm{H}_{4}-2-\mathrm{OMe}\right)_{2}\right\} \mathrm{AlEt}\right]$
Formula: $\quad \mathrm{C}_{30} \mathrm{H}_{27} \mathrm{AlO}_{4}$

Figure 1. Perspective view of the $\left[\left\{\mathrm{C}_{2}\left(\mathrm{C}_{6} \mathrm{H}_{4}-2-\mathrm{O}-\right)_{2}\left(\mathrm{C}_{6} \mathrm{H}_{4}-2-\mathrm{OMe}\right)_{2} \mathrm{AlEt}\right]\right.$ molecule showing the atom labelling scheme. Non-hydrogen atoms are represented by Gaussian ellipsoids at the $20 \%$ probability level. Hydrogen atoms are not shown.

$1.030\left[F_{0}^{2} \geq-3 \sigma\left(F_{0}^{2}\right)\right]$
${ }^{a}$ Obtained from least-squares refinement of 7587 centered reflections.
${ }^{b}$ Programs for diffractometer operation, data collection, data reduction and absorption correction were those supplied by Bruker.
cSheldrick, G. M. Acta Crystallogr. 1990, A46, 467-473.
${ }^{d}$ Sheldrick, G. M. SHELXL-93. Program for crystal structure determination. University of Göttingen, Germany, 1993. Refinement on $F_{0}{ }^{2}$ for all reflections (all of these having $\left.F_{0}^{2} \geq-3 \sigma\left(F_{0}^{2}\right)\right)$. Weighted $R$-factors $w R_{2}$ and all goodnesses of fit $S$ are based on $F_{0}^{2}$; conventional $R$-factors $R_{1}$ are based on $F_{0}$, with $F_{0}$ set to zero for negative $F_{0}{ }^{2}$. The observed criterion of $F_{0}^{2}>2 \sigma\left(F_{0}^{2}\right)$ is used only for calculating $R_{1}$, and is not relevant to the choice of reflections for refinement. $R$-factors based on $F_{0}{ }^{2}$ are statistically about twice as large as those based on $F_{0}$, and $R$-factors based on ALL data will be even larger.
${ }^{e}$ Flack, H. D. Acta Crystallogr. 1983, A39, 876-881. The Flack parameter will refine to a value near zero if the structure is in the correct configuration and will refine to a value near one for the inverted configuration.
$f S=\left[\Sigma w\left(F_{0}^{2}-F_{\mathrm{c}}{ }^{2}\right)^{2 /(n-p)}\right]^{1 / 2}(n=$ number of data; $p=$ number of parameters varied; $w$ $=\left[\sigma^{2}\left(F_{0}^{2}\right)+(0.0469 P)^{2}+0.1476 P\right]^{-1}$ where $\left.P=\left[\operatorname{Max}\left(F_{0}^{2}, 0\right)+2 F_{\mathrm{c}}^{2}\right] / 3\right)$.
$g R_{1}=\Sigma| | F_{\mathrm{o}}\left|-\left|F_{\mathrm{c}}\right|\right| \Sigma\left|F_{\mathrm{o}}\right| ; w R_{2}=\left[\Sigma w\left(F_{0}^{2}-F_{\mathrm{c}}{ }^{2}\right)^{2} / \Sigma w\left(F_{0}{ }^{4}\right)\right]^{1 / 2}$.

## A-18: Complex 50. [\{E-C $\left.\left.\mathbf{C}_{2}\left(\mathrm{C}_{6} \mathrm{H}_{4}-2-\mathrm{O}-\right)_{2}\left(\mathrm{C}_{6} \mathrm{H}_{4}-\mathbf{2 - O M e}\right)_{2}\right\}(\mathrm{AlEt})\left(\mathrm{AlEtCl}_{2}\right)\right]$

- Chapter 4 -

## XCL Code: JMSO101

Date: 18 May 2001
Compound: [ $\left.\mathrm{C}_{2}\left(\mathrm{C}_{6} \mathrm{H}_{4}-2-\mathrm{OMe}\right)_{2}\left(\mathrm{C}_{6} \mathrm{H}_{4}-2-\mathrm{O}-\right)_{2}(\mathrm{AlEt})\left(\mathrm{AlCl}_{2} \mathrm{Et}\right)\right]$
Formula: $\quad \mathrm{C}_{32} \mathrm{H}_{32} \mathrm{Al}_{2} \mathrm{Cl}_{2} \mathrm{O}_{4}$

Figure 1. Perspective view of the $\quad\left[\left\{\mathrm{C}_{2}\left(\mathrm{C}_{6} \mathrm{H}_{4}-2 \text { - } \mathrm{OMe}\right)_{2}\left(\mathrm{C}_{6} \mathrm{H}_{4}-2-\mathrm{O}-\right.\right.\right.$ $\left.)_{2}(\mathrm{AlEt})\left(\mathrm{AlCl}_{2} \mathrm{Et}\right)\right]$ molecule showing the atom labelling scheme. Nonhydrogen atoms are represented by Gaussian ellipsoids at the $20 \%$ probability level. Hydrogen atoms are not shown.

${ }^{a}$ Obtained from least-squares refinement of 4627 centered reflections.
${ }^{b}$ Programs for diffractometer operation, data collection, data reduction and absorption correction were those supplied by Bruker.
${ }^{c}$ Beurskens, P. T.; Beurskens, G.; Bosman, W. P.; de Gelder, R.; Garcia Granda, S.; Gould, R. O.; Israel, R.; Smits, J. M. M. (1996). The DIRDIF-96 program system. Crystallography Laboratory, University of Nijmegen, The Netherlands.
${ }^{d}$ Sheldrick, G. M. SHELXL-93. Program for crystal structure determination. University of Göttingen, Germany, 1993. Refinement on $F_{0}{ }^{2}$ for all reflections (all of these having $F_{0}^{2} \geq-3 \sigma\left(F_{0}^{2}\right)$ ). Weighted $R$-factors $w R_{2}$ and all goodnesses of fit $S$ are based on $F_{0}{ }^{2}$; conventional $R$-factors $R_{1}$ are based on $F_{0}$, with $F_{0}$ set to zero for negative $F_{0}^{2}$. The observed criterion of $F_{0}^{2}>2 \sigma\left(F_{0}^{2}\right)$ is used only for calculating $R_{1}$, and is not relevant to the choice of reflections for refinement. $R$-factors based on $F_{0}{ }^{2}$ are statistically about twice as large as those based on $F_{0}$, and $R$-factors based on ALL data will be even larger.
${ }^{e} S=\left[\Sigma w\left(F_{0}^{2}-F_{c}^{2}\right)^{2 /(n-p)}\right]^{1 / 2}(n=$ number of data; $p=$ number of parameters varied; $w$ $=\left[\sigma^{2}\left(F_{0}^{2}\right)+(0.0278 P)^{2}+41.1247 P\right]^{-1}$ where $\left.P=\left[\operatorname{Max}\left(F_{0}^{2}, 0\right)+2 F_{\mathrm{c}}{ }^{2}\right] / 3\right)$.
$f_{R_{1}}=\Sigma| | F_{0}\left|-\left|F_{c}\right|\right| \Sigma\left|F_{0}\right| ; w R_{2}=\left[\Sigma w\left(F_{0}^{2}-F_{c^{2}}\right)^{\left.2 / \Sigma w\left(F_{0}^{4}\right)\right]^{1 / 2} .}\right.$

## A-19: Complex 52. $\left[\left\{\mathrm{C}_{\mathbf{2}}\left(\mathrm{C}_{6} \mathbf{H}_{4}-\mathbf{2 - O}-\right)_{\mathbf{2}}\left(\mathrm{C}_{6} \mathbf{H}_{4}-\mathbf{2 - O M e}\right)_{2}\right\} \mathrm{TiCl}_{2}\right]$

- Chapter 4 -

## XCL Code: JMS0009 <br> Date: 4 April 2000

Compound: $\quad\left[\left\{\mathrm{C}_{2}\left(\mathrm{C}_{6} \mathrm{H}_{4}-2-\mathrm{OMe}\right)_{2}\left(\mathrm{C}_{6} \mathrm{H}_{4}-2-\mathrm{O}-\right)_{2}\right\} \mathrm{TiCl}_{2}\right] \cdot 0.25 \mathrm{C}_{6} \mathrm{H}_{14}$
Formula: $\quad \mathrm{C}_{29.5} \mathrm{H}_{25.5} \mathrm{Cl}_{2} \mathrm{O}_{4} \mathrm{Ti}\left(\mathrm{C}_{28} \mathrm{H}_{22} \mathrm{Cl}_{2} \mathrm{O}_{4} \mathrm{Ti} \cdot 0.25 \mathrm{C}_{6} \mathrm{H}_{14}\right)$

Figure 1. Perspective view of the $\left[\left\{\mathrm{C}_{2}\left(\mathrm{C}_{6} \mathrm{H}_{4}-2-\mathrm{OMe}\right)_{2}\left(\mathrm{C}_{6} \mathrm{H}_{4}-2-\mathrm{O}-\right)_{2}\right\} \mathrm{TiCl}_{2}\right]$ molecule showing the atom labelling scheme. Non-hydrogen atoms are represented by Gaussian ellipsoids at the $\mathbf{2 0 \%}$ probability level. Hydrogen atoms are not shown.

This structure determination was carried out by graduate research assistant Robert Lam.

${ }^{a}$ Obtained from least-squares refinement of 2675 centered reflections.
${ }^{b}$ Programs for diffractometer operation, data collection, data reduction and absorption correction were those supplied by Bruker.
cSheldrick, G. M. Acta Crystallogr. 1990, A46, 467-473.
${ }^{d}$ Sheldrick, G. M. SHELXL-93. Program for crystal structure determination. University of Göttingen, Germany, 1993. Refinement on $F_{0}{ }^{2}$ for all reflections (all of these having $F_{0}^{2} \geq-3 \sigma\left(F_{0}^{2}\right)$ ). Weighted $R$-factors $w R_{2}$ and all goodnesses of fit $S$ are based on $F_{0}^{2}$; conventional $R$-factors $R_{1}$ are based on $F_{0}$, with $F_{0}$ set to zero for negative $F_{0}{ }^{2}$. The observed criterion of $F_{0}^{2}>2 \sigma\left(F_{0}^{2}\right)$ is used only for calculating $R_{1}$, and is not relevant to the choice of reflections for refinement. $R$-factors based on $F_{0}{ }^{2}$ are statistically about twice as large as those based on $F_{0}$, and $R$-factors based on ALL data will be even larger.
${ }^{e}$ Distances within the solvent $n$-hexane molecule were assigned fixed idealized values: $\mathrm{d}(\mathrm{C} 1 \mathrm{~S}-\mathrm{C} 2 \mathrm{~S})=\mathrm{d}(\mathrm{C} 2 \mathrm{~S}-\mathrm{C} 3 \mathrm{~S})=\mathrm{d}(\mathrm{C} 3 \mathrm{~S}-\mathrm{C} 3 \mathrm{~S} ')=1.50 \AA ; \mathrm{d}(\mathrm{C} 1 \mathrm{~S} \cdots \mathrm{C} 3 \mathrm{~S})=$ $\mathrm{d}\left(\mathrm{C} 2 \mathrm{~S} \cdots \mathrm{C} 3 S^{\prime}\right)=2.45 \AA$ (primed atoms are related to unprimed ones via the crystallographic inversion center ( $0,0,0$ )).
 $=\left[\sigma^{2}\left(F_{0}^{2}\right)+(0.1655 P)^{2}\right]^{-1}$ where $\left.P=\left[\operatorname{Max}\left(F_{0}^{2}, 0\right)+2 F_{\mathrm{c}}^{2}\right] / 3\right)$.
$g_{R_{1}}=\Sigma| | F_{0}\left|-\left|F_{\mathrm{c}}\right|\right| \Sigma\left|F_{\mathrm{o}}\right| ; w R_{2}=\left[\Sigma w\left(F_{0}^{2}-F_{\mathrm{c}}{ }^{2}\right)^{2} / \Sigma w\left(F_{0}{ }^{4}\right)\right]^{1 / 2}$.

Anisotropically-refined atoms are marked with an asterisk (*). The form of the anisotropic displacement parameter is: $\exp \left[-2 \pi^{2}\left(h^{2} a^{* 2} U_{11}+k^{2} b^{* 2} U_{22}+l^{2} c^{* 2} U_{33}+\right.\right.$ $\left.\left.2 k l b^{*} c^{*} U_{23}+2 h l a^{*} c^{*} U_{13}+2 h k a^{*} b^{*} U_{12}\right)\right]$. ${ }^{a}$ Refined with an occupancy factor of 0.6 .
${ }^{b}$ Refined with an occupancy factor of 0.4 . ${ }^{c}$ Atoms of the solvent $n$-hexane molecule were refined with an occupancy factor of 0.5 and a common fixed isotropic displacement parameter.

## A-20: Complex 53. [\{C $\left.\left.\mathbf{C}_{\mathbf{2}}\left(\mathrm{C}_{6} \mathrm{H}_{4}-\mathbf{2 - O}\right)_{\mathbf{2}}\left(\mathrm{C}_{6} \mathbf{H}_{4}-\mathbf{2 - O M e}\right)_{2}\right\}\left(\mathrm{CpTiCl}_{2}\right)(\mathrm{H})\right]$

## - Chapter 4 -

XCL Code: JMS9918
Date: 18 May 2001
Compound: $\quad\left[\left\{\mathrm{C}_{2}\left(\mathrm{C}_{6} \mathrm{H}_{4}-2-\mathrm{OMe}\right)_{2}\left(\mathrm{C}_{6} \mathrm{H}_{4}-2-\mathrm{OH}\right)\left(\mathrm{C}_{6} \mathrm{H}_{4}-2-\mathrm{OTiCl}_{2} \mathrm{Cp}\right)\right] \cdot \mathrm{PhMe}\right.$
Formula: $\quad \mathrm{C}_{40} \mathrm{H}_{36} \mathrm{Cl}_{2} \mathrm{O}_{4} \mathrm{Ti}\left(\mathrm{C}_{33} \mathrm{H}_{28} \mathrm{Cl}_{2} \mathrm{O}_{4} \mathrm{Ti} \cdot \mathrm{C}_{7} \mathrm{H}_{8}\right)$

Figure 1. Perspective view of the $\left[\left\{\mathrm{C}_{2}\left(\mathrm{C}_{6} \mathrm{H}_{4}-2-\mathrm{OMe}\right)_{2}\left(\mathrm{C}_{6} \mathrm{H}_{4}-2-\mathrm{OH}\right)\left(\mathrm{C}_{6} \mathrm{H}_{4}-2-\right.\right.\right.$ $\left.\mathrm{OTiCl}_{2} \mathrm{Cp}\right)$ ] molecule showing the atom labelling scheme. Non-hydrogen atoms are represented by Gaussian ellipsoids at the $20 \%$ probability level. Hydrogen atoms are shown with arbitrarily small thermal parameters except for phenyl hydrogens, which are not shown.

SADABS
0.9678-0.5871
$7166\left[F_{0}^{2} \geq-3 \sigma\left(F_{0}^{2}\right)\right] / 1^{e} / 425$
$0.788\left[F_{0}{ }^{2} \geq-3 \sigma\left(F_{0}^{2}\right)\right]$
${ }^{a}$ Obtained from least-squares refinement of 3966 centered reflections.
${ }^{b}$ Programs for diffractometer operation, data collection, data reduction and absorption correction were those supplied by Bruker.
${ }^{c}$ Beurskens, P. T.; Beurskens, G.; Bosman, W. P.; de Gelder, R.; Garcia Granda, S.; Gould, R. O.; Israel, R.; Smits, J. M. M. (1996). The DIRDIF-96 program system. Crystallography Laboratory, University of Nijmegen, The Netherlands.
${ }^{d}$ Sheldrick, G. M. SHELXL-93. Program for crystal structure determination. University of Göttingen, Germany, 1993. Refinement on $F_{0}{ }^{2}$ for all reflections (all of these having $F_{0}^{2} \geq-3 \sigma\left(F_{0}^{2}\right)$ ). Weighted $R$-factors $w R_{2}$ and all goodnesses of fit $S$ are based on $F_{0}^{2}$; conventional $R$-factors $R_{1}$ are based on $F_{0}$, with $F_{0}$ set to zero for negative $F_{0}^{2}$. The observed criterion of $F_{0}^{2}>2 \sigma\left(F_{0}^{2}\right)$ is used only for calculating $R_{1}$, and is not relevant to the choice of reflections for refinement. $R$-factors based on $F_{0}{ }^{2}$ are statistically about twice as large as those based on $F_{0}$, and $R$-factors based on ALL data will be even larger.
${ }^{e}$ An idealized geometry was imposed upon the intramolecular hydrogen-bonded interaction ( $\mathrm{O} 3-\mathrm{H} 3 \mathrm{O} \cdots \mathrm{O}$ ) by constraining the atoms $\mathrm{O} 3, \mathrm{O} 4, \mathrm{C} 32$ and H 3 O to lie in the same plane (more precisely, to occupy a tetrahedron of volume no larger than 0.05 $\AA^{3}$ ).
$f_{S}=\left[\Sigma w\left(F_{0}^{2}-F_{\mathrm{c}^{2}}\right)^{2} /(n-p)\right]^{1 / 2}(n=$ number of data; $p=$ number of parameters varied; $w$ $=\left[\sigma^{2}\left(F_{0}^{2}\right)+(0.0340 P)^{2}\right]^{-1}$ where $\left.P=\left[\operatorname{Max}\left(F_{0}^{2}, 0\right)+2 F_{\mathrm{c}}^{2}\right] / 3\right)$.
$g R_{1}=\Sigma| | F_{\mathrm{o}}\left|-\left|F_{\mathrm{c}}\right|\right| / \Sigma\left|F_{0}\right| ; w R_{2}=\left[\Sigma w\left(F_{0}^{2}-F_{\mathrm{c}}^{2}\right)^{2 / \Sigma} w\left(F_{0}^{4}\right)\right]^{1 / 2}$.

Table 2. Atomic Coordinates and Equivalent Isotropic Displacement Parameters

Anisotropically-refined atoms are marked with an asterisk (*). The form of the anisotropic displacement parameter is: $\exp \left[-2 \pi^{2}\left(h^{2} a^{* 2} U_{11}+k^{2} b^{* 2} U_{22}+l^{2} c^{* 2} U_{33}+\right.\right.$ $\left.\left.2 k l b^{*} c^{*} U_{23}+2 h l a^{*} c^{*} U_{13}+2 h k a^{*} b^{*} U_{12}\right)\right]$.

## A-21: Complex 59. $\left[\boldsymbol{E}-\left\{\mathrm{C}_{2}\left(\mathrm{C}_{6} \mathrm{H}_{4}-\mathbf{2 - O}-\right)_{2}\left(\mathrm{C}_{6} \mathrm{H}_{4}-2-\mathrm{OMe}\right)_{2}\right\} \mathrm{Ti}(\mathrm{AlClEt})_{2}\right]$

- Chapter 4 -

XCL Code: JMS0104<br>Date: 6 April 2001

Compound: [ $\left.\left[\mathrm{C}_{2}\left(\mathrm{C}_{6} \mathrm{H}_{4}-2-\mathrm{O}-\right)_{2}\left(\mathrm{C}_{6} \mathrm{H}_{4}-2-\mathrm{OMe}\right)_{2}\right\} \mathrm{Ti}(\mathrm{AlClEt})_{2}\right]$
Formula: $\quad \mathrm{C}_{36} \mathrm{H}_{42} \mathrm{Al}_{2} \mathrm{Cl}_{2} \mathrm{O}_{4} \mathrm{Ti}$

Figure 1. Perspective view of the $\left[\left\{\mathrm{C}_{2}\left(\mathrm{C}_{6} \mathrm{H}_{4}-2-\mathrm{O}-\right)_{2}\left(\mathrm{C}_{6} \mathrm{H}_{4}-2-\mathrm{OMe}\right)_{2} \mathrm{Ti}\left(\mathrm{AlClEt}_{2}\right)_{2}\right]\right.$ molecule showing the atom labelling scheme. Non-hydrogen atoms are represented by Gaussian ellipsoids at the $\mathbf{2 0 \%}$ probability level. Hydrogen atoms are not shown.

largest difference peak and hole 1.205 and $-0.631 \mathrm{e} \AA^{-3}$
${ }^{a}$ Obtained from least-squares refinement of 4282 centered reflections.
${ }^{b}$ Programs for diffractometer operation, data collection, data reduction and absorption correction were those supplied by Bruker.
${ }^{\text {c}}$ Sheldrick, G. M. Acta Crystallogr. 1990, A46, 467-473.
${ }^{d}$ Sheldrick, G. M. SHELXL-93. Program for crystal structure determination. University of Göttingen, Germany, 1993. Refinement on $F_{0}{ }^{2}$ for all reflections (all of these having $F_{0}^{2} \geq-3 \sigma\left(F_{0}^{2}\right)$ ). Weighted $R$-factors $w R_{2}$ and all goodnesses of fit $S$ are based on $F_{0}^{2}$; conventional $R$-factors $R_{1}$ are based on $F_{0}$, with $F_{0}$ set to zero for negative $F_{0}^{2}$. The observed criterion of ${F_{0}}^{2}>2 \sigma\left(F_{0}^{2}\right)$ is used only for calculating $R_{1}$, and is not relevant to the choice of reflections for refinement. $R$-factors based on $F_{0}{ }^{2}$ are statistically about twice as large as those based on $F_{0}$, and $R$-factors based on ALL data will be even larger.
${ }^{e} S=\left[\Sigma w\left(F_{0}^{2}-F_{c}^{2}\right)^{2 /(n-p)}\right]^{1 / 2}(n=$ number of data; $p=$ number of parameters varied; $w$ $=\left[\sigma^{2}\left(F_{0}^{2}\right)+(0.0753 P)^{2}\right]^{-1}$ where $\left.P=\left[\operatorname{Max}\left(F_{0}{ }^{2}, 0\right)+2 F_{c}^{2}\right] / 3\right)$.
$f_{R_{1}}=\Sigma| | F_{0}\left|-\left|F_{\mathrm{c}}\right|\right| \Sigma\left|F_{0}\right| ; w R_{2}=\left[\Sigma w\left(F_{0}{ }^{2}-F_{\mathrm{c}}{ }^{2}\right)^{2 / \Sigma w}\left(F_{0}{ }^{4}\right)\right]^{1 / 2}$.

Anisotropically-refined atoms are marked with an asterisk (*). The form of the anisotropic displacement parameter is: $\exp \left[-2 \pi^{2}\left(h^{2} a^{* 2} U_{11}+k^{2} b^{* 2} U_{22}+l^{2} c^{* 2} U_{33}+\right.\right.$ $\left.\left.2 k l b^{*} c^{*} U_{23}+2 h l a^{*} c^{*} U_{13}+2 h k a^{*} b^{*} U_{12}\right)\right]$.

${ }^{b}$ Programs for diffractometer operation, data collection, data reduction and absorption correction were those supplied by Bruker.
${ }^{c}$ Beurskens, P. T.; Beurskens, G.; Bosman, W. P.; de Gelder, R.; Garcia Granda, S.; Gould, R. O.; Israel, R.; Smits, J. M. M. (1996). The DIRDIF-96 program system. Crystallography Laboratory, University of Nijmegen, The Netherlands.
${ }^{\text {d}}$ Sheldrick, G. M. SHELXL-93. Program for crystal structure determination. University of Göttingen, Germany, 1993. Refinement on $F_{0}{ }^{2}$ for all reflections (all of these having $F_{0}^{2} \geq-3 \sigma\left(F_{0}^{2}\right)$ ). Weighted $R$-factors $w R_{2}$ and all goodnesses of fit $S$ are based on $F_{0}{ }^{2}$; conventional $R$-factors $R_{1}$ are based on $F_{0}$, with $F_{0}$ set to zero for negative $F_{0}^{2}$. The observed criterion of $F_{0}^{2}>2 \sigma\left(F_{0}^{2}\right)$ is used only for calculating $R_{1}$, and is not relevant to the choice of reflections for refinement. $R$-factors based on $F_{0}{ }^{2}$ are statistically about twice as large as those based on $F_{0}$, and $R$-factors based on ALL data will be even larger.
${ }^{e} S=\left[\Sigma w\left(F_{0}{ }^{2}-F_{c}^{2}\right)^{2 /(n-p)}\right]^{1 / 2}(n=$ number of data; $p=$ number of parameters varied; $w$ $=\left[\sigma^{2}\left(F_{0}^{2}\right)+(0.0369 P)^{2}\right]^{-1}$ where $\left.P=\left[\operatorname{Max}\left(F_{0}^{2}, 0\right)+2 F_{\mathrm{c}}^{2}\right] / 3\right)$.
$f_{R_{1}}=\Sigma| | F_{\mathrm{o}}\left|-\left|F_{\mathrm{c}}\right|\right| / \Sigma\left|F_{\mathrm{o}}\right| ; w R_{2}=\left[\Sigma w\left(F_{0}^{2}-F_{\mathrm{c}}^{2}\right)^{2 / \Sigma} w\left(F_{0}^{4}\right)\right]^{1 / 2}$.

Anisotropically-refined atoms are marked with an asterisk (*). The form of the anisotropic displacement parameter is: $\exp \left[-2 \pi^{2}\left(h^{2} a^{* 2} U_{11}+k^{2} b^{* 2} U_{22}+l^{2} c^{* 2} U_{33}+\right.\right.$ $\left.2 k l b^{*} c^{*} U_{23}+2 h l a^{*} c^{*} U_{13}+2 h k a^{*} b^{*} U_{12}\right)$ ]. ${ }^{a}$ Refined with an occupancy factor of 0.5 .

## A-23: Complex 72. [2,7 $\_\mathrm{Bu}_{2}-\mathbf{1 , 8}-\left\{\left(\mathrm{C}_{4} \mathrm{H}_{8} \mathbf{O}\right) \mathrm{Cl}_{3} \mathbf{T i O}\right\}_{2}$-fluorene]

- Chapter 5 -

## XCL Code: JMS9812

Date: 26 November 1998
Compound: [2,7- $-\mathrm{Bu}_{2}-1,8-\left\{\left(\mathrm{C}_{4} \mathrm{H}_{8} \mathrm{O}\right) \mathrm{Cl}_{3} \mathrm{TiO}\right\}_{2}$-fluorene]
Formula: $\quad \mathrm{C}_{29} \mathrm{H}_{40} \mathrm{Cl}_{6} \mathrm{O}_{4} \mathrm{Ti}_{2}$

Figure 1. Perspective view of the $\left[2,7-t \mathrm{Bu}_{2}-1,8-\left\{\left(\mathrm{C}_{4} \mathrm{H}_{8} \mathrm{O}\right) \mathrm{Cl}_{3} \mathrm{TiO}_{2}\right.\right.$-fluorene $]$ molecule showing the atom labelling scheme. Non-hydrogen atoms are represented by Gaussian ellipsoids at the $20 \%$ probability level. Hydrogen atoms are shown with arbitrarily small thermal parameters.

${ }^{\text {c S Sheldrick, G. M. Acta Crystallogr. 1990, A46, 467-473. }}$
${ }^{d}$ Sheldrick, G. M. SHELXL-93. Program for crystal structure determination. University of Göttingen, Germany, 1993. Refinement on $F_{0}{ }^{2}$ for all reflections except for 6 having $\left.F_{0}^{2}<-3 \sigma\left(F_{0}^{2}\right)\right]$. Weighted $R$-factors $w R_{2}$ and all goodnesses of fit $S$ are based on $F_{0}{ }^{2}$; conventional $R$-factors $R_{1}$ are based on $F_{0}$, with $F_{0}$ set to zero for negative $F_{0}{ }^{2}$. The observed criterion of $F_{0}{ }^{2}>2 \sigma\left(F_{0}{ }^{2}\right)$ is used only for calculating $R_{1}$, and is not relevant to the choice of reflections for refinement. $R$-factors based on $F_{0}{ }^{2}$ are statistically about twice as large as those based on $F_{0}$, and $R$-factors based on ALL data will be even larger.
eS $=\left[\Sigma w\left(F_{0}{ }^{2}-F_{\mathrm{c}}^{2}\right)^{2 /(n-p)}\right]^{1 / 2}(n=$ number of data; $p=$ number of parameters varied; $w$ $=\left[\sigma^{2}\left(F_{0}^{2}\right)+(0.0728 P)^{2}+13.7401 P\right]^{-1}$ where $\left.P=\left[\operatorname{Max}\left(F_{0}{ }^{2}, 0\right)+2 F_{\mathrm{c}}^{2}\right] / 3\right)$.
$f_{R_{1}}=\Sigma| | F_{0}\left|-\left|F_{\mathrm{c}}\right|\right| \Sigma\left|F_{0}\right| ; w R_{2}=\left[\Sigma w\left(F_{0}^{2}-F_{\mathrm{c}}^{2}\right)^{\left.2 / \Sigma w\left(F_{0}^{4}\right)\right]^{1 / 2} .}\right.$

[^4]:    * The chemical shifts of the Grignard reagents were obtained by removing volatiles from the solution of the corresponding commercial Grignard reagents, then redissolving in THF- $\mathrm{d}_{8}$.

[^5]:    ${ }^{6}$ Chemical shifts of $\mathrm{TiBn}_{4}$ in $\mathrm{C}_{6} \mathrm{D}_{6}(\mathrm{ppm})$ : $7.77(o), 6.93(p), 6.61(m), 2.82\left(-\mathrm{CH}_{2} \mathrm{Ph}\right)$.

[^6]:    ${ }^{\text {c }}$ The compound 39 was separately prepared by mixing the ligand 7 and four equivalents of $\mathrm{EtAlCl}_{2}$ in THF and crystallized from toluene-pentane.

[^7]:    ${ }^{d}$ Selected interatomic angles (deg): $\mathrm{Ol}-\mathrm{NaI}-\mathrm{Ol}^{\prime}=87.4, \mathrm{Ol}-\mathrm{Na}$-[centroid of $\left.\mathrm{C} 21 \sim \mathrm{C} 26\right]=100.8, \mathrm{Ol}{ }^{-}-\mathrm{Na}-$ [centroid of $\mathrm{C} 21 \sim \mathrm{C} 26$ ] $=120.6 ; \mathrm{O3}-\mathrm{Na} 6-\mathrm{OS}=86.4, \mathrm{O} 3-\mathrm{Na} 6$-[centroid of $\mathrm{C} 61-\mathrm{C} 66]=122.0, \mathrm{O}-\mathrm{Na} 6-$ [centroid of $\mathrm{C} 61 \sim \mathrm{C} 66$ ] $=102.6 ; \mathrm{O} 3-\mathrm{Na} 5-\mathrm{O} 5=86.6, \mathrm{O} 3-\mathrm{Na} 5$-[centroid of $\mathrm{C} 41 \sim \mathrm{C} 46$ ] $=102.7, \mathrm{O} 5-\mathrm{Na} 5-$ [centroid of C41~C46] $=119.6$.

[^8]:    ${ }^{\text {e }}$ Average of the two split signals.

[^9]:    ' The weight of the sample was changing during the weighing, thus did not allow accurate analysis, according to the eoemental analysis technitian. The samples were wrapped doubly in preweighed tin boats in the drybox and brought out for quick weighing and analysis. This method works for most air- and moisture-sensitive compounds. This particular sample, however, may have reacted with oxygen or moisture in the atmosphere.

[^10]:    ${ }^{2}$ Complete removal of toluene from the mixture made it difficult to dissolve again.
