NOTICE

The quality of this microfiche is heavily dependent upon the quality of the original thesis submitted for microfilming. Every effort has been made to ensure the highest quality of reproduction possible.

If pages are missing, contact the university which granted the degree.

Some pages may have indistinct print especially if the original pages were typed with a poor typewriter ribbon or if the university sent us a poor photocopy.

Previously copyrighted materials (journal articles, published tests, etc.) are not filmed.

Reproduction in full or in part of this film is governed by the Canadian Copyright Act, R.S.C. 1970, c. C-30. Please read the authorization forms which accompany this thesis.

THIS DISSERTATION

Date... June 8, 1981

DEDICATION

I would like to dedicate this study to my two children,
Ajolie' Cherie and Tawnya Michele, who provided the perfect
impetus for investigating the mood states of
pre-adolescents.

ABSTRACT

The state of one's mood at any given time has long been associated with the occurrence of certain behavioral probabilities (e. g., Kantor, 1923; Nowlis & Nowlis, 1956; Pribram, 1970; Ryle, 1950; Skinner, 1957; Wyatt, 1932), nonetheless, it was not until the early 1950's that any thoroughgoing studies of this introspective area were attempted (Nowlis, 1961 & 1970); and, such research has been, to the present day, exclusively directed towards the adult realm. No investigations have been aimed at delineating the affective experiences of children, and in particular, those of pre-adolescents. The purpose of the present study, therefore, was first to determine the mood structure of youngsters aged seven to twelve, and then to relate this to findings in the adult domain.

Using already established adult mood adjectives, a preliminary list of 447 state-descriptive words and phrases was compiled. In order to ensure item-suitability for pre-adolescents, each word (or phrase) was assessed for comprehensibility and frequency within grades three through six. Additionally, the least frequent word of any of the "redundant-synonym" or antonym pairs, such as "angry" - "mad" or "happy" - "unhappy" was removed from the listing. As a countercheck on the utility of the remaining 114 items, two forms of a pilot instrument were constructed and administered during the first phase of this study.

The pilot phase was, essentially, a verbal comprehension and association session given to several classes of third grade pupils. Phase 2 involved reduction of these data to 81 mood adjectives which had produced the greatest number of "meaningful mood associators". Additionally, it included the development of a measure which was derived from these items, and the testing of this instrument on 597 pupils in grades three through six. Correlation matrices for these children were submitted to principal component analyses, using varimax rotations. After five exploratory analyses were run, a final six-factor solution was obtained for each of the four sample groups of males ($n=312$) and females ($n=282$; grades were combined for each gender analysis), and grades 3/4 ($n=311$) and grades 5/6 ($n=283$; sexes were combined for each analysis within the grade divisions).

Factor-matching across samples yielded six meaningful unipolar dimensions, nonetheless, because of sex and age differences on factor loadings, selection of items to define a factor was individually done for each gender and grade division (3/4 vs 5/6). A factor was defined by those words or phrases which had an absolute loading of .35 or greater, with factor names being determined by a perusal of the aggregate meaning of these items, and on the basis of names given to similar factors in the adult domain. The six factors for both sexes and age groups in order of decreasing percentage of variance were: *Surgency, Sadness, Aggression,*

**Mastery/Self-Esteem, Depersonalization/Fatigue, and
Frustration/Embarrassment.**

These findings were discussed in terms of replicability across gender and grades, as well as in reference to similarity between pre-adolescent and adult factors.

Additionally, the effects of diurnal variation on mood were assessed and found to be significant on the first five factors, again replicating some findings of the adult literature. Implications for the future development of an appropriate pre-adolescent state measure, similar to the adult mood adjective checklists, are indicated, with further research possibilities being discussed based on its development.

ACKNOWLEDGEMENTS

It is with pleasure that I acknowledge the assistance of a number of people who contributed to the production of this thesis. Without the cooperation of over 1,000 individuals, including parents, teachers, and children, this research would not have been possible. And, foremost among these is my supervisor, Dr. Edgar Howarth, whose enthusiasm and expertise in the area encouraged me to undertake this project in the first place.

Grateful acknowledgement is also made to the Edmonton Public School Board for allowing me to come into their schools, and to Dr. Jim Battle of the Bureau of Child Study, who made the initial contact with each principal of the schools involved. A very special thanks, of course, is reserved for the principals, teachers, and children of the following Edmonton elementary schools: Brightview, Crestwood, Glendale, High Park, Westglen, and Youngstown.

I wish, in addition, to express my gratitude to my committee members, Dr. Marvin Roth and Dr. Donald Spearman, for their thoughtful comments and criticisms.

Lastly, I would like to thank my best friend (and husband), Dr. Edward M. Gates, for providing loving support and encouragement throughout--even during the "moodiest" of times.

I. INTRODUCTION

Ruckmick, in 1936, stated that "in the description of moods we...have neither a long literature on the subject behind us...nor any experimental work of note" (p.72). As was true almost half a century ago regarding the entire state area, so too is it true for the arena of child mood states. In fact, a comprehensive review of the mood literature, undertaken in collaboration with my supervisor and reported elsewhere (Howarth & Schokman-Gates, 1981), indicates that there has not been a single study conducted which could be veritably termed a query into such affective childhood experiences.¹ On the other hand, several investigators have focused attention on at least one trait-state descriptor--that of childhood anxiety (Castaneda, McCandless, & Palermo, 1956; Sarason, Davidson, Lighthall, Waite, & Ruebush, 1960; and Spielberger, 1970). But, here too, researchers are forced to conclude "that despite the significances which are attributed to anxiety in the development of the child, systematic research {into its affective state} is practically nonexistent" (Sarason et

¹Although several recent studies using pre-adolescent children have attempted to either assess their mood, or actually induce a specific mood (e.g., Barnett, King, & Howard, 1979; Bourgeois-Bailetti, & Cerbus, 1977; Cameron, 1975; Rosenhan, Underwood, & Moore, 1974; Underwood, Froming, & Moore, 1977), none has used an objective method to determine the effectiveness of their procedures. Others, such as Barton and Cattell (1974), or Lira, White, and Finch (1977), have employed adult state measures with adolescent subjects. This latter procedure appears to be a common practice when the subjects used are within their teen years (McNair, Lorr, & Droppelman, 1971b; Zuckerman & Lubin, 1965).

al., p.81).

Yarrow (1979) notes that, just as with an adult, the child's mood state may have a very profound affect on his interactions with the environment: "Feelings may facilitate or interfere with learning; they may enhance attention to stimuli or they may bias perception and distort interpretation of events. When a child is joyful, he or she is likely to be aware of different aspects of a situation and interpret it differently than when angry" (p.953). Yarrow then goes on to emphasize the need for specific mood measuring techniques in order to delineate the important roles which emotions play in child development.

Likewise, Sarason et al. (1960) and Spielberger, Anton, & Bedell (1976) have noted the deleterious effects of negative mood state on the child's classroom performance, while Izard (1960) has found positive affect to be significantly associated with enhanced intellective functioning, and greater receptivity to the environment. Such findings would appear to be of considerable relevance to the school situation, and yet, no systematic studies of this area have been undertaken.

Perhaps a primary reason for the dearth of scientific concern in this field rests on the fact that there is presently available no instrument which could be considered

appropriate² for measuring the affective states of pre-adolescents. In fact, Sarason et al. assert that "the absence of attempts to even develop such a measure has made it extremely difficult to determine the comparability of findings from different studies" (p.82), since such investigations have employed everything from projective assessments to the behavioral ratings provided by parents and/or teachers.

Although there have been various instruments devised for the measuring of personality in the pre-adolescent group³-the most notable being the downward extension of Cattel's 16PF (Porter, Cattell, & Ford, 1968)--no such consideration has been given to the state aspect of personality, with the possible exception of Spielberger's *State-Trait Anxiety Inventory for Children* (Spielberger, Edwards, Lushene, Montuori, & Platzek, 1973). But this measure too may have its problems, for (1) due to the method of development, Spielberger's adult inventory (Spielberger, Gorsuch, &

²As mentioned previously, the only objective measures of mood that have been used for children have been the adult forms of the mood adjective checklist. Such usage implies that state structure in children is identical to that of the adults, as well as assuming that the mood descriptive items have similar comprehensibility and connotative levels for both groups. As Lira, White, and Finch (1977) noted, even some adolescents found these adjectives to have very little meaning in regard to their fluctuating levels of mood state, with in fact, "a number of the adjectives {being} absent from the lexicon of this population" (p. 535). Results such as this indicate the need for an age-appropriate multiple mood instrument.

³A perusal of Buros (1970), Comrey et al. (1973), Chun et al. (1975) and Johnson and Bonmarito (1971) indicates that there is a considerable number of childhood personality tests, rating scales, and adjustment measures.

Lushene, 1970) has been found to actually be a measure of stress and depression, rather than one of trait and state anxiety (Cattell, 1973); and (2) Endler (1978) notes that the children's version may thus, likewise, be contaminated. Additionally, even though the STAIC does purport to measure the "subjective, consciously perceived feelings of apprehension, tension, and worry" (Spielberger et al., p.3), its restricted focus and age range (nine to twelve years old) obviate any utility it may have for assessing the multiple mood states of pre-adolescent children. Consequently, due to the lack of appropriate state scales (see footnote 2), the major intent of this study was first to determine the mood structure of pre-adolescents, and then to relate this to findings in the adult realm, in order to expedite the construction of a pre-adolescent state measure which may relate the latter to the former.

Integral to this investigation was the use of the factor-analytic strategy (Kelly, 1967) in order to determine answers to the following four queries:

- 1) Can one general dimension of state fluctuation account for the affective experiences of the pre-adolescent (i.e., are the moods of such youngsters still, as yet,

* A comprehensive series of studies carried out by Cattell and his associates revealed "that source traits are not significantly fewer at the child level and that they appear to be of the same nature--behaving more like abilities than dynamic interest traits. Moreover, matching shows them to have essentially the same identities" (Cattell, 1973, p.97). Thus, a further matter of interest to me was that of determining whether mood states might also have parallel forms in the adult and child populations.

largely undifferentiated)?

- 2) Are the affective states of pre-adolescents generally similar?
- 3) Are there replicated marker (see footnote 15) patterns with each of the major mood factors found in these children?
- 4) In what ways, if any, do these childhood mood factors differ from those of the adult? ⁵

Development Overview

Before the investigation of any personality variable, certain preliminary steps must be taken dependent upon the construct employed. For my specific purposes, a review of the relevant literature was undertaken in order to satisfy the following objectives:

- 1) to determine the present state of the mood measurement field, including the possible existence of a pre-adolescent multiple mood measure;
- 2) to examine presently-used child personality and adult mood instruments as a guide to developing an appropriate test format;
- 3) to locate and assemble an age-appropriate source pool of state adjective descriptors; and
- 4) to select the most suitable method of presentation and analysis in order to compare child mood dimensions with

⁵Concomitant with this objective will be the investigation of diurnal effects on the children's mood levels, since time-of-day variance has been found in the adult realm (e.g., Taub & Berger, 1974).

those of the adult.

Based on the subsequent information gathered regarding these objectives, the developmental method used in this study consisted of two distinct phases.

II. PHASE 1: PILOT TESTING

A. Rationale for Phase 1: Item Selection and Pilot Testing

In the preceding chapter comment was directed towards the importance of studying moods, in general, and those of children, in particular. Turning now to the method for investigating such childhood personality factors, a number of considerations must be related in detail. To this end, Chapters II and III will deal with the methods used for the two distinct phases of the study, each corresponding to its developmental aspects as noted in Chapter I.

A measuring technique which appears to be most appropriate for the present study is that of the mood adjective checklist (MACL). As Masterson (1975) noted in her critique of this procedure, "the adjective checklist is unparalleled as a personality technique...since it is easy to administer and score, yet can be complex enough to cover a broad range of behaviors; {the adjective checklists} typically present subjects with a meaningful and nonthreatening task which meets with a minimum of subject resistance; they can be analyzed a variety of ways, both rationally and empirically; and they are... a valid source of information in personality assessment" (pp.303, 305). Additionally, their use within the adult population is fairly extensive--in fact, it is the measure of choice in the majority of mood studies (Nowlis, 1965 & 1970)--with many investigators considering the MACL to be "the best of

all the self-report measures.... in many respects equal to objective behavioral measures" (Radloff & Helmreich, 1968, p. 48).

Accordingly, the main reason for employing an MACL in this study, was the fact that almost all research on adult mood dimensions has been primarily carried out with the use of this measure (Howarth & Schokman-Gates, 1981). Most of our existing knowledge of mood dimensions is based upon (a) application of checklists by various investigators, and (b) subsequent delineation of a number of mood factors (Table 1). It will be noted in this table, that all ten of the studies have used adults, that nine of these have employed factor analysis, and that while there is no absolute agreement, some similarity of emerging dimensions may be seen. The eight main factors in the literature, therefore, may be categorized as follows: *optimism/well-being/surgency*, *sadness/depression*, *anger/hostility*, *sleep vs vigor*, *concentration vs confusion*, *anxiety*, *agreeable/social affection*, and *egotism*. It was my expectation that some, though not necessarily all, of these adult factors might also appear in the pre-adolescent population. And, consequently, if I had hoped to equate child mood structure with that of the adult, I had to of course use the same type of measuring instrument. Nevertheless, due to the problems inherent to research with immature subjects (Cattell, 1973), none of the presently-employed MACLs could be considered suitable for investigating the domain of childhood mood.

states. Accordingly, the first step in this study was determining just which adjective descriptors would be efficacious for use with pre-adolescents.

Using already established mood adjectives, and words taken from a perusal of appropriate word lists⁶, a preliminary compilation of state descriptive words and phrases was determined (see Appendix, Table A). Such mood connotations were not restricted to mere feeling adjectives, but they also included those functional and behavioral aspects which are often found to be manifestations of various mood states--for example, a phrase such as, "I ~~feel~~ like crying" (Jacobson, 1957).

From this list of 447 items, a reduced set of 81 mood descriptors was arrived at by the following means: 1) After assessing each word (or phrase) as to its comprehensibility, via the Thorndike-Lorge word book (1952) and Rinsland's Basic Vocabulary for Elementary School Children (1945)⁷, only those mood descriptors which were found to be of high frequency in grades three through six were retained for stage two of the winnowing process. 2) From this new list,

⁶The actual sources included in this selection process were: Brodie, 1973; Castaneda, McCandless, & Palermo, 1956; Davitz, 1970; Gough, 1952; Howarth, Note 1; Lipsitt, 1958; Lorr, Daston, & Smith, 1967; McNair, Lorr & Dropelman, 1971a,b; Meyers (cited in Radloff & Helmreich, 1968); Nowlis & Green, 1965; Russell & Mehrabian, 1977; Spielberger, 1970; Wessman & Ricks, 1966; and Zuckerman & Lubin, 1965.

⁷Due to the out-dating of word usage and/or increased sophistication of elementary school children, additional use was also made of two newer word frequency corpora; Weprman's and Hass' A Spoken Word Count (1969), and The American Heritage Word Frequency Book of Carroll, Davies, and Richman (1971).

the least "frequent" word of any of the "redundant-synonym" or antonym pairs, such as "angry"- "mad" or "happy"- "unhappy", was then removed. And 3) as a countercheck on the utility of the remaining 114 items (since geographic as well as temporal factors were different from the above-used sources), two forms of a pilot instrument were next constructed and administered.

B. Procedure for Phase 1: Pilot Testing of Mood Descriptive Words

The pilot testing was, essentially, a verbal comprehension and association session given to several classes of third grade pupils. Each form of the "Word Recall Test" was presented to a different class in one of Edmonton's lower socio-economic elementary schools. It was assumed that if a "feeling" word or phrase was *meaningfully* understood by these seven- and eight-year olds, then such items could safely be included in a measure which spans the upper elementary school years.

Subject Sample .

The two third-grade classes, divided by form, sex, and age, resulted in the following sample composition:

1. Form A, 9 males: 2 seven-year olds and 7 eight-year olds
2. Form A, 12 females: 3 seven-year olds and 9 eight-year olds
3. Form B, 15 males: 1 seven-year old and 14 eight-year olds

4. Form B, 10 females: 2 seven-year olds and 8 eight-year olds

Although a very small n was used in this phase of the study, it was not considered to be of any real significance since the testing merely served as a further validating and winnowing-down process for those descriptors previously chosen on the basis of frequency counts.

Pilot Instrument

The pilot instrument consisted of 114 mood descriptors which had previously been determined as falling within the comprehension range of third grade pupils (see prior section of this chapter). Due to such a large number of items, it was thought adviseable to only present one half of this amount to any particular group of children. Consequently, the mood descriptors were arranged in alphabetical order, with every even-numbered item comprising Form A, and every odd-numbered one comprising Form B. To the right of each mood descriptor there was a line provided for the child to write down what he understood the word to mean (see Appendix for the forms and exact instructions)*.

Because I wanted the children to take this activity seriously in order to obtain an accurate assessment of their

*Although the methods were independently developed, an analogous procedure has been used with trait descriptors in order to determine whether or not there exists an adult consensus regarding the connotations of such terms: Fiske and Barack (1976) found that "despite the individuality of interpretations, the item sampling produced parallel, practically interchangeable scales {with those having been originally provided as the stimuli}" (p.339), thus indicating the existence of broad connotative consensus.

comprehension of mood descriptors, both forms of the measure were titled "Word Recall Test". Due to the students' prior history with classroom exams, it was assumed that by having the word "test" at the top of this two-page form, the children would more readily attend to the task at hand.

Procedure

The two classes were visited on the same morning during November, 1979, between 9:00 and 10:20 A. M. I first introduced myself to the children, and then passed out the "Word Recall Test", explaining that I was interested in finding out certain things about girls and boys who were in the third grade.

After asking for descriptive information, I then told the children that they were going to work through the list of 57 words together with me:

I'll first read out the number, and then the word which follows it. What I would like you to do, is to write down two words which could describe feelings or moods you might have that are related to the word. For example, when I look at the word "glad", I think of the words "happy" and "smiling", because if I were glad about something, then I'd be happy and I'd feel like smiling.

Because young children have a tendency to dawdle when there are no time strictures, the classes were told that they would have 1/2 minute to write down each set of their two mood associators. Hence, when 30 seconds had elapsed from the reading of the prior item, I then instructed the children to look at the next number and word. The approximate time for each session then, was 40 minutes,

including the additional 10 minutes necessary for introductions, instructions, and test distribution.

Treatment of Data

A tally was made of all "meaningful mood associators" (MMAs) which the 46 children had written down to the mood descriptive stimuli. A word or phrase was defined as an MMA if it was 1) a mood synonym to the test item, such as "unhappy" given to the stimulus word "sad"; or 2) a response which could be readily associated with the test item, such as the word "proud" given to that of "brave". Idiosyncratic associators, although plausibly connected with the stimuli, were not included in the final tally. Examples of these associators would be non-mood words such as "straight" and "smooth" given to "palm", or evaluative words such as "bad" and "ugly" given to "cocky". Antonyms also were excluded, since it would be impossible to tell whether the child actually understood the stimulus word's meaning: "Scared" is probably an MMA to "hopeless", but if it is given to "hopeful", then the child may just be confusing the two "hoping" words.

Figure 1 provides a distribution of response frequency, while Table 2 presents an alphabetical listing for those terms which had MMA values of 14 or more (based on 1 for each MMA given), or which were, themselves, often-cited MMAs. It will be noted in Figure 1 that each "x" represents one item which has an MMA value equal to the frequency count given by the abscissa. The maximum MMA value for any item on

** often-cited MMAs which were not original mood stimuli words

Form A would be 42, while this number for Form B would be 50. These values were derived from the fact that each child was asked to give two responses per mood word or phrase, and there were 21 and 25 children, respectively, who completed these forms. The cut-off point of 14 for acceptable terms, was chosen because it included approximately the top 60% of items as based on their MMA frequency of occurrence. Due to the fairly stringent requirements for acceptable MMAs (as presented in the prior paragraph), as well as the fact that those items which comprised both forms had already been assessed as to their comprehensibility for third grade pupils, it was believed that this top 60% would be a fairly solid base from which to begin the factor analytic study. Thus, from the original 114 mood descriptors submitted to this winnowing process, a total of 67 well-understood items resulted. To this list were added 14 more words supplied by the children as common MMAs, for an aggregate of 81 mood descriptive terms. It was from this base of 81 items that Phase 2 was begun.

III. Phase 2: Factor Analytic Investigation of Mood Structure

A. Rationale for Phase 2: Factor Analysis of Mood Structure

Royce (1950), noted that the "proper order" for any research program consists of three major steps: First, a factor analysis should be carried out on the selected set of a priori measures in order to determine both its basic factor structure and any other sources of variance operating.⁹ Following this procedure, an analysis of variance for each of these "basic" factors should be conducted as a means of ascertaining the effects of demographic and situational variables. And last, carefully controlled laboratory experimentation may then be implemented with the knowledge that probable sources of error have already been determined. Due to its exploratory nature, this study employed steps one and two, with consideration being given to step three in the Discussion chapter of this manuscript.

Within the first step of such a research program, various research designs are possible depending upon the purposes of the study. The one most commonly associated with the mood area is that of R-technique factor analysis (all of

⁹Fairly limpid presentations of this approach have been provided by Comrey (1973), Kim and Mueller (1978a,b), and Shontz (1965), with five main steps being delineated: 1) proper selection of the variables; 2) computation of the correlation matrix; 3) extraction of the unrotated factors; 4) rotation of these factors; and 5) adequate interpretation of the rotated factor matrix.

the factor analytic studies noted in Table 1 were based on the R-method). In this design, correlations between scales, and/or items within those scales, are obtained from a large group of subjects on one occasion. These intercorrelations then form the basis for the factors, which represent reduced subgroups of the original items. Such new groupings are capable of distinguishing among subjects as efficiently as did the larger number of initial measures. In addition to providing the means for more concise instruments, the R-technique design may also allow for the discovery of basic mood structure. Moreover, because the area of mood study has been virtually built upon such a technique, and, in order to allow for a comparable comparison to known state dimensions in the adult, the factor analytic strategy was determined to be the procedure most appropriate for use in the present investigation. It is to the further elucidation of this investigation that we now turn,

B. Procedure for Phase 2: Testing of Pre-Adolescent Mood Structure

Subject Sample

This phase of the study involved the participation of 597 pre-adolescent pupils chosen from six schools in the Edmonton Public School District.¹⁰ Grades three through six

¹⁰One caveat of the factor analytic method is that subjects should total not less than three times the number of variables being investigated (Cattell, 1973), with "acceptably good studies" using at least five times as many persons as items (Cattell, 1978; Nunnally, 1978).

were represented, as were students within several of the remedial learning groups, and all levels of socioeconomic strata. All children within these classes who were present on the day of testing were included in the study, with the exception of eight children whose parents had not consented to their participation (see Appendix for permission slip form). The 35 classes, divided by grade and sex, resulted in the sample distribution presented in Table 3.

Mood Structure Measure

Because prior research into adult mood structure has been primarily based on the factor analysis of various mood adjective checklists (see previous section of this chapter), it was deemed appropriate to investigate the mood structure of children in the same manner. Accordingly, the measure used employed an MACL format, with modifications introduced in order to account for any lack of pre-adolescent ability to discriminate among various shadings of feeling states.

In reference to this latter consideration, a forced-choice answer format was believed to be the most applicable for the seven- to twelve-year old range, "since children are {assumed to be} not capable of so balanced a use of the middle {or additional} alternatives as are adults" (Porter, Cattell, and Ford, 1968, p.6). Further, because the measure was intended to be given within a group setting and to a large number of subjects, its format needed to be as simple as possible.

Table 3
Subject Distribution for Phase 2

GROUP	GRADE			(ten classes)(seven classes)
	3 (eight classes)	4 (ten classes)	5 (ten classes)	
Females				
n	64	83	76	61
mean age	8.09	9.18	10.15	10.97
age range	7-9 years	8-10 years	9-11 years	10-12 years
Males				
n	86	81	82	64
mean age	8.33	9.12	10.23	11.17
age range	7-10 years	8-10 years	9-12 years	10-12 years

Note. Heavy lines demarcate the four separate subject groups used in the final factor solutions of this study: Females vs Males (grades combined) and Grades 3 & 4 vs Grades 5 & 6 (sexes combined).

Toward these ends, the instrument consisted of 81 items, listed alphabetically on four pages (two sheets, front and back), to which the child was asked to respond by either checking the "Yes" or "No" space provided (see Appendix for measure and exact instructions). The items used were those state descriptors from Phase 1 which had been determined as having meaningful mood connotations for third grade students. Because it was felt that some children might react negatively to such a long list of items, the form was printed on colored paper, left untitled, and presented in as non-threatening a manner as possible.

Procedure

The 35 classes were individually tested during the months of November and December, 1979, after I had previously met with each teacher and principal of the schools involved. Convenient times were arranged with each instructor, resulting in the following distribution for the six school-day periods:

- 1)beginning of school day--6 classes
- 2)just prior to morning recess--10 classes
- 3)school period prior to lunch--6 classes
- 4)school period following lunch--4 classes
- 5)just prior to afternoon recess--4 classes
- 6)last period of the school day--5 classes

I first introduced myself to the children, and then passed out the untitled orange form and a computer-scored answer sheet explaining that I was interested in finding out

a few things about elementary school children.

After asking for the customary descriptive information to be written on the answer sheet, I then directed the children to look at the instructions at the top of the orange form as I read them aloud. Since it was necessary for the children to cognitively transfer their answers from the orange questionnaire to the white answer sheet, I went through the first item with each of the classes:

Look at statement 1 on this page {the mood questionnaire}. It says "Right now I feel good".....Yes No . Now look at number 1 on your answer sheet. If you feel good right now,¹²please fill in the "Y" or "Yes" box next to this number just as I'm doing on this sheet {see Appendix for example sheet}. If your answer is "No", then fill in this "N" box. We want your true feelings, so mark the first answer you think of after reading each statement.

In order to give even the slowest readers enough time to mark each of their answers, a seven-minute completion period was allotted for each page of items. To discourage dawdling, however, a reminder was given at the end of these

"Although it is realized that the usage of "good" in this context was grammatically incorrect, it was decided that, due to its colloquial frequency, "Right now I feel good" served as a very clear example for what was being asked of the children.

¹²An emphasis was placed upon the immediate feeling ("right now"), since prior research has shown that the time interval covered by the instructions has a great influence on determining whether the measure is tapping states or traits (e.g., Martin, 1959; McNair & Lorr, 1964; Zuckerman, Persky, & Link, 1967). Additionally, "by making the checking of each word a commitment of the moment and not of a lifetime, we make the test a prompt or probe....Thus the verbal responses and feelings which vary together with other responses in a mood are endorsed with greater probability in that mood than at other times. The subject is not describing his mood...he is publicly noticing his mood and feelings" (Nowlis, 1963, p. 78).

seven-minute intervals: "Almost everyone has now started on page 2 {or 3, or 4}. If you are not on page 2 {or 3, or 4} yet, please work a little faster." Additionally, a final reminder was given to the children concerning the total number of items they should have filled in on their answer sheets by the time they had reached the last statement on the mood questionnaire.

Treatment of Data

Information from each of the children's data sets was key-punched separately onto two standard IBM data cards. The 81 dichotomous items were assigned values of 1="Yes" and 2="No", while females were coded as 0 and males as 1. School grade also entered into the analysis, with 3, 4, 5, and 6 serving as codes for the third through sixth grades, respectively. Additionally, diurnal variation was considered, with values of 1 through 6 representing the six previously-determined school periods.

The possibility of response set was considered prior to the actual analysis, with a perusal of the data sheets revealing position or acquiescent sets for only three of the children.¹³ Therefore, from the original 597 data sets, 594 were included in the final result procedures. The few

¹³Third-grade pupils were the respondents on all of the biased sets, with two of those children having been recruited from the remedial learning group; the third youngster was of Metis extraction, and appeared to have trouble reading the test material. The position effects noted in this study then, appeared to be related more to attention span and levels of comprehension, than to any inherent characteristics of the measure or the testing situation.

missing responses which were present were handled by randomly assigning a "yes" or "no" value to each.

Separate analyses of variance and multiple comparisons were first run on subgroups of grades and sex in order to determine the appropriate subject composition for the factor analyses. Additionally, these procedures were used to ascertain which, if any, time-of-day effects were present in the data.

The factor method chosen for this study was that of principal-component analysis (with principal axes extraction), followed by varimax rotation. In this type of factor analysis, unities are retained in the principal diagonal of the correlation matrix instead of placing estimates of communality in these slots. By using unities in the diagonal the analysis will maximize the sum of the square loadings of each factor, thereby accounting for more of the variance than would loadings obtained by any other method. Because factor analysis is now widely-accepted as being concerned with the linear combination of actual variables, "...to compute that loading from the correlation of sums, the formulas require that unities be placed in the diagonals of the correlation matrix. If anything other than unities are placed in the diagonal spaces, one is not correlating an *actual variable with a linear combination of actual variables*" (Nunnally, 1967, p. 348). Moreover, both Nunnally and Mulaik (1972) note that when exploratory factor studies employ over 20 variables, it really doesn't matter

what values are placed in the diagonals since the resulting factor loadings are almost identical for both principal-component and principal-factor analyses. Thus, they strongly recommend the use of PC plus varimax, since the latter is an orthogonal-rotation method which simplifies the actual factors-themselves, and tends to produce invariant solutions even though changes may occur in the test battery.¹⁴ "This combination of methods has worked so well for exploratory factor analysis that it becomes hard to improve upon. When an investigator is dissatisfied with the PC plus Varimax solution, usually it is because no simple, clear factor solution could be obtained by any method" (Nunnally, 1978, p. 385). Furthermore, Crawford and Ferguson (1970) and Cooley and Lohnes (1962) have noted that where the number of optimal factors is unknown, then the use of Varimax is highly preferred over any other.

Notwithstanding such enthusiasm, considerable discussion has revolved around the use of "little jiffy" (e.g., Cattell, 1973; Cooley & Lohnes, 1962; Lee & Comrey, Note 2), as this two-phase method is often called (Kaiser, 1970; Kaiser & Rice, 1974). Nevertheless, it was considered prudent for the present study to employ this technique due to both its utility in exploratory work, and its extensive

¹⁴When the purpose of a factor analysis is to allow inferences regarding the basic structure of a personality domain on the basis of only a sample of variables from that domain, such an invariance property must be viewed as of the utmost importance: Slight changes in the sample of variables used would not be found to affect the basic inferences drawn, and thus, a more veridical structure may be obtained.

use in the personality domain. Additionally, since the major fault of the method concerns the use of inappropriately low cut-off points (eigenvalues) for factor extraction, the present investigation utilized very conservative values in the analyses: Instead of the commonly-used Kaiser-Guttman criterion (Kaiser, 1961; Guttman, 1954) of employing all unrotated factors that have eigenvalues of >1.0 prior to rotation, the first analysis used in this study set the minimum eigenvalues at $>2\%$ of the number of variables factored (Howarth & Browne, 1971). In this case, mineigen was 1.6, which would ensure that only components accounting for greater than 2% of the total variance would be treated as significant. With 81 variables, 328 correlations would be expected to reach a .05 significance purely by chance; by increasing the mineigen used, the influence of these spurious relationships would be decreased. Furthermore, when more than 50 variables are present in the analysis, the Kaiser-Guttman criterion has a tendency towards greatly over-estimating the number of dimensions involved (Linn, 1968; Velicer, 1977), by drawing uninterpretable factors into the analysis (Heise, 1973-1974).

Two other important decisions to be made before running a factor-analytic program are the number of factors to be extracted and the value of the variable loadings which will be accepted as adequate for factor definition. In reference to the first consideration, the number of factors extracted depends both upon the minimum eigenvalue set and the

communality estimates placed in the diagonal. Since unities are used in the PC method, the mineigen becomes of prime importance for the first analysis. Further honing of these results may then be accomplished by several methods, including 1) the use of a graphic representation of eigenvalues (Cattell, 1966b), so that natural breaks in the degree of slope¹⁵ may indicate the number of factors necessary (the "Scree test"); 2) the use of all factors which have at least three loadings of >3.5¹⁵; 3) the use of factors whose number is approximately one-quarter the number of original variables and whose aggregate is found to account for 50%-75% of the total variance (Overall & Klett, 1972); 4) the use of a "substantive importance" criterion for setting the minimum proportion of the total variance which can be explained by any retained factor (Kim & Mueller, 1978b); and 5) the use of interpretable factors which account for 40%-60% of the total variance and have some inter-item correlations >.3 (Armor, 1973-1974).

Notwithstanding the various "number of factors" methods, or perhaps because of them, the most effectual criterion is believed to be a combination of techniques: "Accept only those conclusions that are supported by several independent criteria....the final judgement has to rest on the reasonableness of the solution on the basis of current

¹⁵One common fault cited by Guilford (1967) and Cattell (1978) is the extraction of too many factors for the number of variables employed: A good rule is to have at least three markers (fairly highly loaded variables) for every factor, with five being considered adequate (Comrey, 1973).

standards of scholarship in one's own field. This criterion is elusive, but fortunately or unfortunately, all of us must live with it in order to communicate our findings to our fellow scientists" (Kim & Mueller, 1978b, p.45).

A final consideration for any "structure-finding" factor analytic study is the issue of factor congruence across subject populations. Henrysson's monograph (1957) devotes considerable attention to the need for this congruence in exploratory factors, for even if simple structure has been reached, there is scant proof that the factors are elemental in the sense that they have any explanatory powers:

A single factor analysis yields more or less unverified hypotheses as to factors which must be proved invariant through other factor studies employing other tests and in respect of other populations, before it can be said that the factors found have the generality required of factors with explanatory properties. (p. 111)

Accordingly, there are several research designs available which may be of service in verifying or refuting the existence of factor invariance. One of these, the configurational invariance method (factor similarity), was used in the present investigation.

The configurational invariance method (Thurstone, 1947) employs the analysis of responses given by different populations to the same set of variables. If caution is taken in regard to the sample populations (e.g. comparisons should not be made between 10 year-old boys and 60 year-old women since the putative factors would most assuredly be

different), then the size of factor loadings should be affected in proportion to the changes in variance of the different test items over the populations. This implies, of course, that the two factor structures are indeed congruent, for if that is so, then the configurations of these loadings should also be congruent.

Testing for such invariance involves not only statistical methods, such as Tucker's congruence coefficients, but also analysis of the structure content in order to ensure psychological similarity. When the factor matrices have been thus determined, they can be rotated together via a Procrustes solution,¹⁶ at which time they are viewed as being invariant.

¹⁶The Procrustes method of "confirmatory" analysis entails the forced rotation of one variable matrix in order that it may approximate an hypothesized factor structure. In essence, Procrustes solution provides the best estimate of a "target" factor matrix taken from a sample correlation or loading matrix, with the hypotheses to be confirmed being set by the nature of the target matrix (Nunnally, 1978). For my study, Matrix B was the target for factor congruence, while Matrix A received the forced rotation in Tables 5-7.

IV. Results

Descriptive statistics for males and females within each grade were computed separately (see Table 3 for subject distribution), with a clear demarcation being evident between the sexes, and between the lower and upper two grades (anova and multiple comparisons tables are obtainable from the author).¹⁷ Due to this finding it was decided to run separate factor analyses on each sex within the combined grades of three/four and five/six.

The 81 variables described previously were intercorrelated for each of the four subgroups by means of the Pearson product-moment correlation coefficient. Factoring first for the above-noted "2% components" in each of the subgroups, it was discovered that too many uninterpretable factors had been extracted: The factors extracted to criterion ($\lambda_{mineigen} = 1.6$) for males (ME34) and females (FE34) in the two lower grades each totalled 14, with "adequate" ($\geq .35$) and multiple loadings (more than three items) only on the first 10 factors. ME56 and FE56 showed similar patterning, although these older subgroups revealed one less factor at 13 each, with males having appropriate loadings on all 13, while females had them only on the first 10. Moreover, interpretable factors within each

¹⁷ Another common fault in many multivariate studies is the premature inclusion of diverse populations within the same analysis. As Guilford (1967) noted, it is inappropriate to pool data derived from different sexes and ages (grades in this case) for the purpose of computing intercorrelations, unless it can be shown that the differences between the populations on the test variables are insignificant.

subgroup were not consistent across the sex/grade samples. The four 81X81 matrices and the results of this first, inadequately-determined, factoring may be obtained from the author.

As Cattell noted (1973), "a single factoring, no matter how large the sample, proves nothing. In every one-shot factoring there are a few degrees of rotational uncertainty...only the massive verdice (sic) of consistency over experiments, populations, age groups, and so forth is good enough for conclusions on personality structure" (p. 285). Considering this caveat for factor-matching along with the results of the initial factoring, it was deemed prudent to do a further factoring on the correlation matrices.

Based on the immediate evidence of at least ten interpretable factors in each subgroup, as well as the frequently-found number of ten adult mood dimensions (Nowlis, 1965), a second factor analysis was conducted using the PC method, with specification being made for nfactors=10, instead of the prior mineigen value of 1.6. This analysis too, however, proved inadequate; for not only were there less than 10 factors having appropriate loadings for ME34 and FE56 (eight and nine, respectively), but in all subgroups there were found to be some variables which were highly-loaded on more than one factor (results may be obtained from the author). Since independent mood dimensions were an expectancy, I did not consider it appropriate to use factors which were "contaminated" in this manner, for it

might be indicative of a "degenerative fission" wherein one "actual" factor is found to split into two (Cattell, 1965). Of course, final selection of items for any future measure would entail the elimination of these reoccurring variables, but several of the factors upon which these items loaded did appear to be very similar in nature. Thus factoring, at $n\text{factors}=8$,¹⁸ was carried out.

Results from this analysis (obtainable from the author) indicated that once again too many factors had been extracted--at the most I was getting six fairly-robust mood dimensions, albeit different variables were loading on these factors across subgroups. A final reduction in the number of factors, then, was used to lessen these discrepancies.

The $n\text{factors}=6$ analysis provided four fairly clear-cut dimensions across three of the four sex/grade samples: *surgeency* (optimistic vitality), *sadness*, *aggression*, and *mastery/self-esteem*.¹⁹ The fourth group, females in the

¹⁸The choice of eight factors was made on the same basis as that for ten: 1) If I hoped to get factor-matching across the sample of populations, I needed to measure at the lowest common denominator; and 2) since the only prior research in this area has been on adults, I had to use those results as guidelines in planning my research--in the adult domain twelve, ten, eight, six, and three mood factors have been determined, as measured by various multiple mood self-report instruments (Howarth & Schokman-Gates, 1981). Nevertheless, because this investigation was into a totally unexplored area, the principle of "factor-matching" would ultimately have to take precedence over that of "dimensions within the adult domain".

¹⁹ There also appeared to be two fairly weak factors of *frustration/embarrassment* and *ergic tension* (Cattell, 1978) present in each of the four subgroups, albeit, these dimensions did not always "load" on the same items across samples.

fifth and sixth grades, did not evince similar loadings for the latter self-esteem dimension. In fact, that dimension for them (noting only the highest-loaded variables) was almost totally different than it was for the other groups, having items such as "bashful", "giggly", "like laughing", "shy", and "strong", as opposed to "brave", "handsome (or) pretty", "powerful", "tough", and "strong" for the rest of the samples (see Tables B-G in the Appendix). In order to attempt a reconciliation of this difference, a final factoring was undertaken for the combined subgroups²⁰ of 1)females (grades 3-6), 2)males (grades 3-6), 3)grades 3/4 (females and males), and 4)grades 5/6 (females and males); correlation and factor matrices for these new analyses may be found in the Appendix, Tables H-K and L-O, respectively.

A. The Final Analysis: Six-Factor Solutions for Gender and Grades

Factor-matching across all four of these subgroups was accomplished for the above-noted mood dimensions of surgency, sadness, aggression and mastery/self-esteem, as

²⁰Although it was realized that a clearer factor solution might be obtained by factoring within the original homogeneous subgroups, Cattell (1978) noted that when a "type-common pattern" is aimed at, it is perfectly legitimate to "obtain the dimensions of a generic or even a composite population, ignoring species variations" (p. 512), since researchers have initially been interested in general patterns, with further specification being carried out using generically-based measures. Likewise, my interest is in finding, first, the general mood dimensions in pre-adolescents, and second, in determining what differences do exist in these general patterns based upon age (grade) and sex variables.

well as for two weaker factors of *frustration/embarrassment* and *depersonalization/fatigue*. A perusal of the first six-factor solutions undertaken (Appendix, Tables B-G), revealed a fission for the *ergic tension* and *frustration/embarrassment* factors in the upper two grades²¹, thus possibly accounting for both the consolidation of an "old" factor (*frustration/embarrassment*) and the emergence of a totally new one in the final factoring: *Ergic tension*, which was believed to involve both positive and negative referents, appeared to now have become integrated into the single negative state of *depersonalization/fatigue*.

The eigenvalues (relative contributions to the total variance) for the six main factors, as well as for the succeeding 10, are shown in Figures 2 and 3. Similarity in each factor's contribution to the variance is observed for all of the subgroups, as is the Scree test indication for the presence of six or seven interpretable factors; by definition (Cattell, 1966b), those factors present beyond that number are seen as being common dimensions produced by a large number of small random errors. Additionally, tests for statistical significance of optimal rotation (Cattell, 1978) and factor congruence (Harman, 1967) indicate that at least the first four mood dimensions were very

²¹*Ergic tension* in females of this age range was a bipolar factor whose negative aspects appeared to have very similar meaning to the negative dimension of *frustration/embarrassment*. On the other hand, males in this age range showed a reversal of the pattern, with *f/e* being bipolar and *ergic tension* revealing similarity to only the former dimension's negative aspects.

Scree Tests on Grades

- adequately-determined.

Table 4 presents rotational significance levels (hyperplane count) of between .01 and .0001 for over 75% of the subgroups' factors, with only the first two factors in the Female and Grades 3/4 samples being greater than .05. No factors reached significance levels of greater than .15, while the majority were found to be less than .0001, thus indicating that simple structure had been reached. By definition, this means that the first six factors which were extracted are "simple and meaningful...since most variables relate highly to only one factor and each factor can be identified as representing that which is measured in common by a relatively small number of variables" (Overall & Klett, 1972).

Likewise, factor similarity, as seen in Tables 5-7, reached significance levels of between .01 and .001 on all six factors for each of the rotated comparisons between subgroups. Coefficients in these tables were tested against criteria set by Tucker, and Schneewind and Cattell (Cattell, 1978, p.253 and pp.568-569), with the rotated matrices representing factors in order of similarity, and the unrotated representing the order of factor occurrence within each subgroup. The congruences were highest for the four main factors of *surgency*, *sadness*, *aggression*, and *mastery/self-esteem*, with the lowest being noted on the dimension of *depersonalization/fatigue*; *frustration/embarrassment* was more erratic in its

Note. Critical $p < .05$ value of Tucker's coefficient for 80 in-common variables on six factors is .32 (Cattell, 1973, p. 253); significant levels other than $p < .05$ are not noted in Tucker's table. The Schneewind-Cattell table (Cattell, pp. 568-569) lists critical values for up to 50 variables. At this number, the critical values for .05, .025, .01, and .001 levels of significance are .24, .29, .38, and .52, respectively. For 80 variables, extrapolation from the table would place any coefficient greater than .30 within the .01 and .001 range of significance.

Note. Critical $p < .05$ value of Tucker's coefficient for 80 in-common variables on six factors is .32 (Cattell, 1972, p.253); significant levels other than $p < .05$ are not noted in Tucker's table. The Schneewind-Cattell table (Cattell, pp.568-569) lists critical values for up to 50 variables. At this number, the critical values for .05, .025, .01, and .001 levels of significance are .24, .29, .38, and .52, respectively. For 80 variables, extrapolation from the table would place any coefficient greater than .30 within the .01 and .001 range of significance.

congruences, maintaining fairly high levels for some comparisons (e.g. between Females and Grades 3/4 at .8529) and low on others (e.g. between Females and Grades 5/6 at .3528). Despite the adequacy of simple structure and the presence of at least three good markers on each factor factor, some dimensions were found to have greater similarity with a factor other than their hypothesized counterpart: For example, *depersonalization/fatigue* in Grades 5/6 was found to be more closely aligned with *aggression* in the lower grades than it was with Grades 3/4's factor of *depersonalization/fatigue* (Table 5, unrotated matrix). Additionally, almost all factors were found to have significant comparisons with at least one other dimension across subgroups, albeit the greatest coefficients were usually maintained for the like-factors.

Tables 8-13 provide information on the marker variables for each of these "in-common" dimensions, while graphic representations of all six factors within the four subgroups, as well as their rotated matrices, may be found in the Appendix, Figures A-D, and Tables G-J. Marker variables were defined as those items which attained loadings of greater than or equal to .35 on any factor.

Interpretation of Factors

Surgency, Factor I As can be seen from the large number of marker variables in Table 8, *surgency* is the predominant mood dimension for both males and females, be they in the lower or upper elementary school grades. Per-cent of

variance accounted for by this factor ranges from a low of 15.8 in the males to a high of 17.5 in the females, with common descriptors such as "cheerful", "excited", "playful" leading to the identification of this dimension as being one of optimistic vitality or *surge*ncy.

Sadness, Factor II

Table 9 presents the next "strongest" mood dimension to be found in pre-adolescent students. Although it is the second factor for both grades and for females, its position is reversed with that of *aggression* in males. This dimension is well-marked by feelings of dejection, sadness, and worthlessness.

Aggression, Factor III

Feelings of anger, bossiness, and physical tension appear to mark this factor. As mentioned above, *aggression* was actually found to be the second mood dimension in males, while it is the third, behind *surge*ncy and sadness, for the other three subgroups. Table 10 presents relevant data for this factor.

Mastery/Self-Esteem, Factor IV

This factor is well-marked by feelings of bravery, physical attractiveness and strength. Interestingly enough, in the upper grades *mastery/self-esteem* is the fifth factor, after *depersonalization/fatigue*. As can be seen in Table 11, the other three subgroups count it as their fourth mood dimension.

Depersonalization/Fatigue, Factor V

Table 11
MOTIVATIONAL FACTOR: MASTERY/SELF-ESTEEM

Based on the average per-cent of variance accounted for by this factor (across subgroups), depersonalization/fatigue appears to be the fifth mood dimension in pre-adolescents. Nonetheless, it was the fourth factor for Grades 5/6, and the sixth factor for both Males and Grades 3/4. Table 12 shows that its identity comes from such markers as "giggly", "tired", and "weird", suggesting that fatigue may produce feelings of estrangement from the self.

Frustration/Embarrassment, Factor VI

Feelings of embarrassment and futility are well-noted for this factor by such markers as "ashamed", "bashful", "like giving-up", and "like whining". This dimension represents the fifth factor for males and Grades 3/4, while it appears as the sixth for upper grades and females. It should be noted that this is the only factor on which the same marker(s) do(es) not appear in at least two sample groups: As Table 13 shows, females and males, along with the lower grades, all share at least two of their variables; the upper grades have no markers in common with these groups, even though their variables may be readily interpreted as loading on a frustration/embarrassment factor.

A note on factor interpretation

Factor analysis cannot name the factors for you; it can, however, provide a statistical basis from which inferences regarding a factor's nature may be made. Therefore, since my main interest was in determining 1) whether or not multiple and differentiated mood states do exist in pre-adolescents,

and 2) whether or not such dimensions are analogous to established adult states, the interpretation process for this study involved comparisons between the child and adult mood factors. In four out of the six pre-adolescent dimensions, high loadings and intra-factor item correlations were found for variables which also appeared in the adult literature. Thus the factor names of "surgey", "sadness", "aggression", and "fatigue" (*depersonalization/fatigue*), were based upon prior-known state dimensions (Table 1). The two remaining factors, "mastery/self-esteem" and "frustration/embarrassment", derived their names from a perusal of the present factor structures, which do not appear to duplicate prior adult dimensions. With highly-loaded markers such as "strong", "powerful", and "handsome (or) pretty", the first dimension was believed to represent environmental mastery, with a concomitance of self-esteem. Likewise, for the remaining factor, "ashamed", "confused", and "embarrassed" markers lend credence to its descriptive label of *frustration/embarrassment*.

Interpretation of these six factors was based on the concept of "factors as descriptive dimensions", capable of summarizing the factorial content of the variable domain sampled. No attempt was made to "reify" these dimensions nor to fictitiously impart meaning to any particular aggregation of items: Even though a factor may be prominently displayed in this phase of the study, it cannot be assumed that all major facets of that mood dimension have been tapped by the

items used, or that even all of the extant pre-adolescent mood states are being represented. As noted previously, as many as 13 independent mood dimensions may be found in this age grouping, albeit some were uninterpretable, while others may merely be unique to the sample. Likewise, the constricted comprehension range obviated the use of other items which might have extended or altered the factor structures obtained.

B. Diurnal Variation in Mood States

As previously-noted, a "properly conducted" research program is first concerned with finding basic structure (via factor analysis), and then with determining the effects of independent variables on this structure (via analysis of variance) (Cattell, 1965; Royce, 1950): "In factor analysis we end by determining what the "factors" are...in analysis of variance we begin with the knowledge of what the factors presumably are, and we test their statistical significance" (Burt, 1966, p.286). In accord with this view, analyses of variance and multiple comparisons were run on the 81 mood variables in order to assess the affects of diurnal variation on mood within sexes and grades. Additionally, factor scores (Comrey, 1973; Nunnally, 1967) were computed using the marker loadings for each dimension within the four sample groups, and then subjected to multiple comparisons via the t-test. Tables 14-17 present 40, 36, 41, and 22 significant differences ($p < .05$) for the 81 variables in the

numbers denote probability levels.

male and female groups, and lower and upper grades, respectively; marker variables were involved in 82.50, 80.56, 80.49, and 81.82% of these cases, indicating that these variables were not only strong markers for their respective factors, but that the majority of them were also sensitive to time-of-day effects.

T-tests over time revealed that the greatest degree and number of significances were present for the *surgency* factor in all groups except that of Grades 5/6; their *aggression* factor was the dimension most affected by time-of-school day. *Frustration/embarrassment* showed no diurnal effects, while *depersonalization/fatigue* was significant for only comparisons in Grades 3/4. *Mastery/self-esteem* was the sole factor which showed time-of-day affects on two groups, with four comparisons being significant for Grades 3/4, and two comparisons for the males.

For all factors affected, the majority of significances appear to be between the morning and afternoon school sessions, with times 1, 4, and 6 being the periods most involved. These mood fluctuations for each group over the course of the school day, are graphically depicted in Figures 4-9. As can be seen from the first three figures (Figs. 4, 5, & 6), all group's began the day with greater feelings of *surgency*, and lesser feelings of sadness and aggression. This pattern, however, changed as the hours past, until the last period, when *surgency* was near its lowest level and sadness and aggression had increased. The

three remaining factors showed various fluctuations during the school day, nevertheless, their beginning and final levels did not reveal any great divergence (Figs. 7, 8, & 9). Because the sets of markers for each factor within the separate subgroups were different, statistical comparison between the groups was not possible. Due to the high degree of factor similarity across the samples however, general comparisons may be made: taken as a whole, then, females and pupils in grades 3 & 4 are shown as feeling consistently more surgent, and less aggressive and masterful, than their male and upper grade counterparts. Additionally, levels of sadness appear to be quite similar across all groups, while feelings of depersonalization/fatigue and frustration/embarrassment are found to be greater for the males and grades 3/4.

V. Discussion

Although much theoretical work has been done in the area of personality, scant use has been made of systematic empirical data in order to derive conceptualizations (Fiske, 1971). One exception to this is in the affective domain, where numerous factor analyses have yielded both reoccurring and unique constructs. Over the last three decades, personality theorists and researchers have been paying increasing attention to the concept of mood, and its various components, as first defined through factor analysis. Such taxonomic endeavors have ultimately led to the consensus "that it is now {considered} meaningful to talk about the structure of {adult} mood", and the very integral part it plays in the total functioning of personality (Hendrick & Lilly, 1970, p.453).

The concept of mood structure has been shown to have considerable validity (Hendrick & Lilly), and although quite complex, its basic factor structure has remained relatively stable over various populations and investigations (see Howarth & Schokman-Gates, 1981, for a review of these). Additionally, because factors are conceived of as being the "primary dimensions²² of individual difference" (Overall & Klett, 1972, p.90), a solid factor structure must meet three primary criteria: 1) conceptual meaningfulness--in order to

²²Factors are said to be primary or elemental in the sense that they represent pervasive personality constructs which have been found in the subject population, and which differ mainly in degree across the individuals in this population.

understand the nature of mood, one must first be able to conceptualize what each of its components represents; 2) relative independence or orthogonality of dimensions--if factors overlap greatly in their structure, conceptual as well as statistical acuity will be lost; and 3) parsimony--if individual differences in the domain of interest cannot be categorized into substantially smaller units than the number of original variables, researchers and theorists alike will become lost in a morass of data points. Associated with these criteria is the requisite evidence for the presence of "real" factors. Nunnally (1967) asserts that if the highly-loaded variables which are used to define a factor have substantial correlations among themselves, while maintaining much smaller values with "other-factor" markers, then direct confirmation has been given for this dimension's validity--a very necessary condition if the entire factor structure is purported to be valid.

In order to meet any of these criteria however, particular attention must first be paid to the actual design and execution of the factor-analytic study. Primary among the several considerations, are those relating to the use of (at *minimum*) 100 or more subjects than there are variables,²³ and to the tests of statistical significance.

²³Cattell (1966a) cites this number of subjects as being "adequate" for a "proper" factor-analytic study, however, as noted before, the majority of researchers in this area maintain that a ratio of from 3:1 to 5:1 would be more appropriate. The present investigation employed a ratio of approximately 3.5:1.

for rotation to simple-structure and number of *interpretable* factors. As a corollary to the latter, inclusion must also be made of at least two or three markers from each of all known factors which may be relevant to the investigation (Cattell, 1966a). Of course, this last criterion may pose a problem when the study is of an exploratory nature into a totally new domain, as was my investigation, but guidance may often be taken from prior research in the adult area, with necessary accommodations being made.

As may also have been apparent from the above discussion, the actual *method* of factor analysis is rather inconsequential, for, although individual marker loadings may differ, if a definite factor structure is present and is found by any one of the methods, then this same structure will be found by the others as well (Nunnally, 1978). And, once this structure has been found, attention should naturally turn to its explication in terms of dependent and independent variables.

Cattell broached this issue in 1965 when he presented arguments regarding the correct usage of factor analysis and anova. As previously-noted, factor analysis can indicate which independent or dependent variables should be of prime concern for statistical testing via the analysis of variance. In order to use this method to the best advantage for my purposes however, factor invariance (similarity) across subgroups had to first be attained (Tables 5-7). Such invariance is considered to be both a necessary and

important condition (Henrysson, 1957) for attributing explanatory significance to the factors--however, it is not sufficient unto itself. And herein lies the utility of such statistical methods as analysis of variance and multiple comparisons, for if the factors are "real" and stable, then non-factorial research will bear this out. Turning now to the four queries of Chapter II, each will be dealt with consecutively and in some detail with respect to the results obtained.

1) Can one general dimension of state fluctuation account for the affective experiences of the pre-adolescent (i.e., are the moods of such youngsters still, as yet, largely undifferentiated)?

As noted in the Results chapter, of the four initial analyses run, factor dimensions were found to total 14 in both sexes of the younger subjects (grades 3 & 4), while the two older groups (grades 5 & 6) each revealed one less factor at 13. Nonetheless, a perusal of both factor loadings, and their possible conceptual meaning, indicated that interpretable factors were not consistent across the sex/grade samples. Four further exploratory analyses on the samples were run, each with criterion set at a successively more stringent level in the hopes that a clear-cut and generalizable set of factors would emerge. The final set of analyses did indicate the presence of six common factor axes based on gender (males vs females) and age (grades 3/4 vs grades 5/6). These solutions had indicated not only the

presence of *interpretable* factors, but also that the change in variance accounted for by each succeeding axis after the sixth had become definitely small. Such occurrences proffer the possibility that either I was investigating a domain whose dimensionality was rather large, or that virtually nothing except error variance was left in the residuals. Actually, both of these proposals may be valid: As may be recalled from the results chapter, the initial set of analyses had produced at least 10 interpretable, albeit occasionally divergent, factors for the four subgroups; the Scree test (Figs. 2 & 3), on the other hand, had indicated the presence of only six or seven "in-common" interpretable factors. Because the per-cent of variance accounted for by these six factors was fairly low (from 34.6 to 37.1 as shown in Tables 8-13), it is reasonable to assume that error variance, as well as the differential effects of gender and age, play a part in defining a generalizable pre-adolescent mood structure.

It would appear then, that males and females in both the lower and upper grades have approximately the same number of mood dimensions, that these mood dimensions are differentiable (more than one unique state dimension is necessary to explain their affective experiences), and that the number of dimensions is similar to that found in adults. Nevertheless, across the age groups of interest, the conceptual meaning of some of these dimensions is found to change towards those of the adult domain indicating that

physical and social maturation may also affect basic mood structure.

Now although this latter finding was of heuristic interest, my main concern was with the more applied area of mood measurement. As noted previously, the major intent of this study was to determine mood structure of pre-adolescents in order to expedite the construction of a pre-adolescent state measure. Integral to this objective was the necessity of discovering the broad general dimensions which are present and capable of being similarly assessed across both sexes and over the upper four elementary school years.

A further finding of interest is that although there is a common-sense assumption (Nowlis, 1963) that moods are bipolar in the sense that one is either in a "good" or "bad" mood or a "happy" or "sad" one, my research indicates pre-adolescent moods to be essentially unipolar. Almost all factors in all subgroups were found to have the greatest number and degree of loadings in the positive direction, if they indeed had any negative loadings at all. The only exception was the dimension of frustration/embarrassment in females, where the two highest markers were "calm" at -.47 and "cooperative" at -.58. Nevertheless, bipolarity cannot be assumed here either, since these two items were more than offset by the other five positively-loaded markers. Similar findings have been replicated many times over in the adult domain (Nowlis, 1970); more attention will be paid to this

issue of uni- and bi-polarity in a later part of the Discussion chapter.

2). Are the affective states of pre-adolescents generally similar?

Factor-matching across samples yielded six conceptually-clear dimensions (as based on adequate loadings and interpretable factors) in pre-adolescent subjects.

Because of sex and age differences on factor loadings, selection of markers to define a factor was done for each sex and within the lower (3/4) and upper (5/6) two grades.

The six factors for the four samples, in order of decreasing mean variance, were: *Surgency, Sadness, Aggression, Mastery/Self-Esteem, Depersonalization/Fatigue, and Frustration/Embarrassment*, as presented in Tables 8-13.

Now although the definition of factors found for each of the subgroups is not identical, nor may be the emotional reactions of any two children within those subgroups,²⁴ it is believed that the six basic dimensions are analogous to one another. Additionally, evidence has been presented in Tables 5-7 for the across-sample congruence of these six pre-adolescent state factors, albeit some factors did appear to be similar to more than one dimension in the comparison group, thus providing further data relating to the affects of maturation on mood structure. For example, the unrotated

²⁴Arnold (cited in Izard, 1965) maintains that when common factors are discovered and used to describe one's emotional state, then that person's subjective experience may be viewed as parallel to, but in no way exactly like, that of another within the same mood state.

matrices of Table 5 show that in older children (grades 5/6) the depersonalization/fatigue factor is more similar to aggression (Tucker's coefficient of .7237) and sadness (.5706) in younger children, than it is to its own counterpart (.2855) in this group; conversely, younger subjects on this factor show the greatest congruence to the older children's dimension of sadness (.4696). No divergent results were found for either of these age groups on that factor (D/F) when compared with the female sample (Table 6), while the 5/6's depersonalization/fatigue dimension did compare to both its own counterpart (.6506) and aggression (.7355) in the males (Table 7). Likewise, frustration/embarrassment in fifth and sixth graders (Table 5) is closest to third and fourth grade sadness (.4696), while this factor in the 3/4's is more similar to the 5/6's dimensions of sadness (.5976) and aggression (.6002). Once more, these divergences were not noted in the lower age group comparisons with gender; the upper grades (Tables 6 & 7) however, showed their F/E factor to be similar to both genders' dimensions of sadness (.3780, .4410), as well as to its own counterpart (.3528) in the female group. Males, on the other hand, revealed fairly strong comparisons between their factor of frustration/embarrassment (Table 7) and those of sadness (.5487) and aggression (.7134) in grades 5/6.

As is evident from these contrasts, some factors which appear to be relatively congruent for one sex and/or age

group, have relatively weak congruence with another group. Prominent among these contrasting factors are the two weaker dimensions of depersonalization/fatigue and frustration/embarrassment especially in the upper grades and males. Nonetheless, because each rotated factor comparison across subgroups reached at least the .01 level of significance, it is valid to state that there are, at a minimum, six similar mood factors within pre-adolescent school children.

~3) Are there replicated marker patterns with each of the major mood factors found in these children?

As noted in the previous section, some congruent factors appear to differ in regard to their relationships across grades and gender. A probable explanation for this is the fact that unique features were present in several of the dimensions--specifically, marker variables were not congruent across all ages and sexes. Marker similarity (Tables 8-13) ranged from a high of 16 "in-common" variables (items which appeared as markers in all four of the factor structures) across subgroups for surgency, to a low of zero on the frustration/embarrassment factor; depersonalization/fatigue was also scant on markers, with only one in-common variable being present. On the other hand, Factor II (sadness) had ten across-group variables, while Factors III and IV (aggression and mastery/self-esteem) had seven and six, respectively. Additionally, certain subgroups were more congruent in their

marker patterns, with males and grades 3/4 having the greatest number of in-common variables at 21 (for the ~~surgency~~ dimension). Females and the upper grades had the most similarity on sadness, depersonalization/fatigue, and frustration/embarrassment at 14, 6, and 4 markers, respectively, while aggression revealed a greater marker-congruence for males and grades 5/6. All comparisons between groups were similar for mastery/self-esteem (in-common variables equaled 6 or 7), except for females and the lower grades where this congruence reached the level of 10 in-common markers.

Taken as a whole then, neither gender nor age alone would have sufficed in determining the mood structure of pre-adolescents. Both must be considered as independent variables when determining this structure, since each brings its own unique patterns of mood to the analysis.

4) In what ways, if any, do these childhood mood factors differ from those of the adult?

If the discipline of personality is indeed interested in the individual differences of humankind, then it must also be interested in that of the child. In the mood area, obviously the first question to be asked in this regard is how often, if at all, state factors found in adults likewise appear in children? This question is of basic relevance to psychology since the growth of a personality variable and "its response to various influences cannot be followed unless it can be located and measured as the same entity

over an appreciable age range" (Cattell, 1973, p.64). As a corollary to this expansion of research into the "normal" child's realm, is the additional prospect of expansion into the state realm of the "abnormal" child--possibilities exist for the marked utility of a child state measure in the clinical area. Of course, some investigators have been cognizant of this need (e.g., Cattell, 1973; Sarason et al., 1960; Spielberger, 1970), nonetheless, no systematic research has ever been undertaken in this field. Cattell (1973, p. 65) offers several explanations for this neglect:

In the first place, one does not want errors from complications in the purely cognitive field while exploring the personality field. With children there are problems of reading and verbal understanding that might force one to forego due representation of certain areas of behavior....Moreover, if the self-perceptions of children--quite apart from language difficulties--should prove to be naive and unstable, it would be a poor place to start trying to define elusive basic structure....Because of these considerations the best strategy has seemed to start with adults and work down. This approach also gives the advantage that the personality sphere can include markers for the adult factors so deliberately and gradually modified for children that a continuity of variables might be established.

Taking careful note of these child-induced complications, as set out in the Method chapters, I was able to determine that from an original 447-item list of adult mood markers, 81 were found by pre-adolescents to have state-descriptive meaning. Factor analytic research on a measure employing these 81 "comprehensible" items was, then undertaken.

As previously noted in the results section, four of the six pre-adolescent mood dimensions did have clear-cut adult counterparts: *surgency*, *sadness*, *aggression*, and *fatigue* (*depersonalization/fatigue*); *mastery/self-esteem* and *frustration/embarrassment* appear to have no analogous adult factor; albeit a few researchers may have presented similar dimensions in combination with another.

The first factor determined in the present study was that of *surgency*. This dimension was also found to be the most robust one in the adult realm. In-common markers for this factor across both my study and those using adults, reveal replications in at least six of the adult-mood investigations mentioned previously.²⁵

In-common markers and replications in the adult domain were also found for the childhood dimensions of *sadness*, *aggression*, and *fatigue*, while McNair and Lorr (1965) presented a tentative factor called *confusion* which appeared to be characterized by bewilderment and "muddleheadedness"; perhaps this latter dimension may be analogous to the *depersonalization/fatigue* dimension of the present study.

Table 18 presents a comparison of the adult factors with those found in the pre-adolescent investigation.

As for the mood dimension of *mastery/self-esteem*, the *egotism factors* which have been found in the adult domain,

²⁵Additionally, Cattell has found this factor to be a primary (source) trait in both children and adults (Howarth & Cattell, 1973; Porter, Cattell, & Ford, 1968)

Table 18

Note. Comparisons are based upon similarity of factor items found in the adult population (Table 1) and those which were markers in the present study (Tables A-13).

have had essentially negative connotations (e.g., "egotistic", "self-centered", and "boastful" as found by Hendrick and Lilly, 1970; Howarth, 1979; Nowlis, 1970; and Nowlis and Green, 1965), whereas the child's dimension represented one of positive and healthy self-regard. Wessman and Ricks (1966) addressed this latter aspect in their monograph on adult mood and personality, when they noted that self-esteem appears to rise when elation is high, and to fall when it is low: "The major changes in self-esteem would appear to be that it becomes much less 'favorable' or 'good' in depression...in depression it seems as if one is judging oneself against an ideal standard and criticizing oneself for being very different from it; in elation it seems as if one's self-concept more clearly approximates one's personal ideal, which is relatively constant" (p. 51). And, so it might be with the child--however, because the pre-adolescent is in such a state of continual flux, perhaps he has not yet derived a "personal ideal", and thus his self-esteem may actually be dependent upon his ability to "master" the immediate situations which present themselves.

In addition to the above-noted comparisons with adult mood factors, attention was also paid to the similarities and divergences found between the six pre-adolescent mood dimensions and the only other state measure available for youngsters--Spielberger's *State Trait Anxiety Inventory for Children* (1970). Out of the 20 items which comprise this single-state measure, eight are found to be marker variables

for five of the pre-adolescent mood factors. These items and the factors they load on are:

- 1) "calm", -aggression (grades 5/6) and
frustration/embarrassment (grades 3/4, males, females)
- 2) "upset", sadness (3/4, 5/6, males, females)
- 3) "nervous", sadness (3/4, females),
depersonalization/fatigue (females), and
frustration/embarrassment (5/6)
- 4) "worried", frustration/embarrassment (5/6), and sadness
(3/4, 5/6, males, females)
- 5) "happy", surgency (3/4, 5/6, males, and females)
- 6) "good", surgency (3/4, 5/6, males, females), and
-aggression (5/6)
- 7) "mixed-up", sadness (3/4, 5/6, males, females), and
depersonalization/fatigue (females)
- 8) "cheerful", surgency (3/4, 5/6, males, females)

As can be seen from this listing, the variables tended to congregate at not only one or two dimensions (as would be expected if they do indeed measure the single state of anxiety), but rather, their dispersal was wide-spread, encompassing all factor dimensions save that of mastery/self-esteem. Looking at these comparisons, one wonders whether the sole use of the empirical method for test construction (as was employed for the STAIC) may give as valid or as comprehensive a set of guidelines as would the joint use of empirical and analytical methods. Perhaps some closure on this issue may be reached by returning to

the question of bi- and uni-polarity in mood factors.

The Bi- versus Uni-Polarity Issue in Mood Research

From an inspection of the STAIC, it became apparent that Spielberger assumed anxiety to be a two-directional dimension. This, however, may have been an incorrect assumption, for as Nowlis asserted, "bipolarity assumed by scientist and layman alike is probably unwarranted. Whereas pairs of semantic opposites, such as elated and depressed or affectionate and hostile, are often thought of as representing opposite poles, our results show that they must be unpaired in mood research, since each occurs on a different orthogonal or near-orthogonal factor" (1963, p. 78). Theoretically, this finding meant that affects often thought to be at opposite ends of the pole, may in actuality vary quite independently of one another, thus being simultaneously present within the same individual. Using several items from the six-factor solutions, an example in the child realm might be the simultaneously high occurrence of all six factors: A youngster who feels "powerful" (mastery/self-esteem) because it was so "great" (surgency) to finally get back at that bully by "hitting" (aggression) him, may also feel "jumpy" (depersonalization/fatigue) and "nervous" (frustration/embarrassment) because he is "worried" (sadness) about getting caught. Thus, because of the transient, and yet complex nature of moods, it is possible to have simultaneously equal or unequal levels of orthogonal state factors which are commonly-assumed to be

opposite in nature.

Notwithstanding the considerable amount of evidence regarding this issue of bi- or uni-polarity, several investigators have found at least partial disconfirmation. Lorr and Shea addressed this problem in 1979, and found that the mood scale properties greatly affected the dimensionality outcomes. When acquiescence or extreme response bias was partialled out of their data, Lorr and Shea found three bi- and one uni-polar mood factors when previously there had been only monopolar dimensions. Their conclusion was "that some moods are bipolar while others are not...{since} semantic opposites need not be psychological opposites" (pp. 471-472). Likewise Svensson (1974) noted that symmetric, as opposed to asymmetric mood rating scales, tended to produce balanced proportions of positive and negative responses which then led to marked bipolar factors. It appears then that the persistent emergence of unidimensional factors in the Nowlis' studies may be at least in part a result of format and instructions, nonetheless, it is still considered to be of vital importance to use research designs which do not preclude the possibility of monopolar factors, since even the proponents of two-dimensionality (Lorr & Shea) were unable to predict which moods would be mono or bi.

In the adjective checklist used for the present study, the response format was dichotomous and yet no bi-polar dimensions were discovered. Either this is an instance of

"some moods are bipolar and others are not", or the response format and instructions had no biasing affect on the children. Two further possibilities are 1) the "actual" dimensionality for mood factors in pre-adolescent is in the mono direction, and 2) the children tested had either not yet become cognizant of social-desirability responses, or if they had, they did not feel threatened enough in the test situation to use them.

Diurnal Variation in Pre-adolescents and Adults

A final issue when discussing the similarities between pre-adolescent and adult mood structure involves the effects of time-of-day variables. In regard to state fluctuations over the course of the junior high school-day, Barton and Cattell (1974) found that when using an adult mood measure afternoon testing resulted in significantly higher scores on anxiety, stress, depression, and regression across both sexes (no age-differentiation was made), while girls maintained high levels of anxiety and extraversion throughout the school day; morning testing produced significantly higher scores for arousal in females and for fatigue in males. Since the actual instrument used by Barton and Cattell was not available, direct comparisons between their study and the present one were not possible, nevertheless, generalizations may be made based on the assumed meanings of the factor names. The sadness factor in pre-adolescents appears to have a counterpart (depression) in the Barton-Cattell study, and accordingly, sadness was

found to be greater in the afternoon across both sexes, with females revealing a consistently higher level for the majority of the day. Likewise, females were significantly more surgent (aroused) at the beginning of the day, while males evinced a similar high score on mid-morning fatigue. Cattell concluded that due to the affect of time-of-day variables on mood dimensions, separate norms for diurnal variation would be of great utility in the state domain. Perhaps the present study, with its explication of pre-adolescent mood factors, will be an impetus to just such work in the child realm.

In the adult domain, diurnal variation has been found to negatively affect concentration, activity, and friendliness, and positively affect fatigue in the early morning vs mid-day hours. On the other hand, late afternoon negatively affected depression and fatigue, and positively affected concentration, relative to the early morning testing. Over-all, positive moods increased both at mid-day and late afternoon, while negative states were found to decrease relative to scores given at the early morning session (Taub & Berger, 1974). In contrast to the adult patterns, the pre-adolescents of the present study revealed greater degrees of positive mood state (surgecy) at the beginning of the day, while negative states (sadness and aggression) became more dominant as the day progressed.

A. Implications of the Study

Common sense beliefs regarding the antecedents and consequents of mood range from practical methods for changing affect, to the assertions about which behaviors may be emitted in this or that mood. Nowlis (1977) lists four classes of occasionally overlapping antecedents: somatic and psychosomatic processes; emotional provocations and counterprovocations; environmental contingencies and habitability; and drugs. Research studies based on these four classes have yielded serendipitous results which have led to new areas of interest, such as how mood states fit into the scheme of long-term personality characteristics, or, as in the case of my study, how child mood states compare to those of the adult. Additionally, investigations have been conducted into the relationships between various consequents, such as attitude, feeling and behavior alterations, and affect. The most notable research at the present however, is in the areas of experimental personality and social psychology, where mood checklists are being employed to investigate the relations between sets of independent and dependent variables (for a review of these studies see Howarth & Schokman-Gates, 1981). It is because of the broad implications posed by these adult mood adjective checklist studies that the explication of pre-adolescent mood structure is so important. For as Howarth and Cattell (1973) noted, no reliable nor valid personality test may be constructed until an adequate

operational definition, based upon the actual pattern of relationships among the data, has been attained. What this implies is that the multivariate approach (especially factor analysis) should be used at an early, rather than at a late stage of test development: it is "a necessary condition for effective bivariate experiment and is a precondition for adequate operational definition" (Howarth & Cattell, p.794), since "the discovery of the number and nature of such response patterns...must precede location and listing of the internal and external stimuli that trigger them" (Cattell, 1966a, p.226). In other words, the researcher needs to know what it is he intends to measure, before an appropriate test can be developed for its measurement. And, in order for the great many adult mood findings to have any relevance to the child area, one must be able to construct an analogous pre-adolescent state instrument. The present research is the first step towards that goal.

Turning now to practical implications for a pre-adolescent mood structure, prominent among these is its utility for exploratory studies in the emotional development of the child. Although affect has long been a cornerstone of the adult psychoanalytic field, very few studies have attempted to relate it to the area of child adaptation and growth.²⁶ Yarrow (1979) maintains that in order to study the

²⁶ Reimanis (1974) found that psychosocial development was significantly related to feelings of happiness and elation in college students, and that a very predictable mood-psychosocial development relationship existed in the adult population.

developmental stages in childhood, "we need to distinguish how children come to recognize their own emotional states, how they learn to recognize the feelings of others, and how they learn to label their own emotions and the emotions of others" (p. 954). Further, Yarrow believes that research is needed to determine how the child develops a positive regard for him/herself, since this form of evaluation in youngsters has been found to be associated with the child's perception of his/her ability to control the immediate environment.²⁷ Nonetheless, "before we can explore these relationships, we need to develop sensitive indices of mastery {in children}" (p. 956). The present investigation may be of great service in this endeavor, since it has determined that mastery and self-esteem are intimately related, appearing, in fact, on the same factor. Additionally, because children are viewed as being "generally unable to sustain moods since they lack ego differentiation, stability of object cathexes, tolerance for tension, and resistance to substitute objects and

²⁷As an interesting sidenote, Lamont and Brooks (1973) have reported that mood level at time of testing significantly affects the scores of Rotter's I-E scale for perception of control. These results indicate that individuals who are depressed perceive themselves as having a lesser degree of control over their environment than do those persons who report higher levels of immediate mood state. This interpretation is likewise found in the study of Harvey and Enzle (1977), where depressed subjects were found to be significantly more dependent on others than were those subjects who evinced an average or elated level of mood. Likewise, Gatchel, Paulus, and Maples (1975) found that a "learned helplessness"-induction procedure produced the decidedly negative moods of anxiety, depression, and hostility. Perhaps the adult relationship between mastery and mood is not all that different from the child's.

"gratifications" (Wessman & Ricks, 1966), just such hypotheses may be tested out once their mood structure has been determined. Thus, the explication and further investigation of this newly-discovered pre-adolescent mood structure, is seen as being of prime importance in furthering these goals.

Positive self-regard has also been viewed as a predictor and determinant of behavior in children. The studies of Coopersmith (1968) and Gelfand (1962) indicate that children's responses to experimental contingencies are significantly related to their immediate feelings of mastery and self-esteem (as assessed by trait indices). In a similar vein, experimentally-induced levels of affect in elementary school children has been found to significantly alter their responses in regard to generosity (Barnett, King, & Howard, 1979; Underwood, Froming, & Moore, 1977). No objective measures of the youngster's actual mood states were taken, however, so the above results rest mainly upon supposition as to the affective dimensions and levels involved.

Because so few child mood studies exist due to the problems in measurement already noted (and none which use an objective measure of multiple state), the remainder of this section will be devoted to implications for child research as found in the adolescent and adult literature. One significant and robust finding in this field is that of "state vs trait" in the prediction of behaviors. Patrick, Zuckerman, and Masterson (1974) and Zuckerman et al. (1967)

obtained results which indicate that a single administration of a trait test is inferior to a test sampling of states when general personality characteristics are to be described, or behavior is to be predicted. Likewise, Gouaux, Lamberth, Friedrich (1972) and Martin (1959) have found that momentary moods are more powerful determinants of interpersonal attraction responses and stress responses, than are the affects of the allegedly-stable traits. Taken together, these and other studies (Zuckerman, 1976) strongly suggest that a state measure given just prior to the incidence of note, be it experimental or not, is more likely to predict individual behaviors in that situation than would a general trait measure. Such findings may have very important implications for the area of child personality, since a more veridical measure of children's traits may actually be found by doing a time-series analysis using repeated testing with state measures. This would give estimates of variability for the dimensions involved, in addition to their mean levels. Further, in the course of such testing, responses to different kinds of situations could be sampled, as could any time-of-day variables. Although such an approach may be time-consuming (depending upon the type of instrument used), it is believed that a more accurate picture of child personality will obtain since it would take into account the powerful effects of

situations and time on mood, and accordingly, on behavior.²⁸

In regard to these powerful effects of situation and time, a number of studies have been conducted which highlight their very cogent relationship to moods. Among these include investigations into sleep deprivation and satiation (e.g., Hendrick & Lilly, 1970; Roth, Kramer, & Lutz, 1976; Taub, Tanguay, & Clarkson, 1976), weather variables (Goldstein, 1972), social climate (Gerst & Sweetwood, 1973), and the home environment (Hughes, 1977). As a companion area to these latter two, attention has also been paid to the calming and stimulating mood affects of music and color, finding both to have significant implications for use in the home and the work-place (Fisher & Greenberg, 1972; Shatin, 1970; Wexner, 1954). Moreover, mood state has been found to be profoundly affected by the emotional reactions one observes in those around him (Abrams & King, 1978), with an imitation theory of affect being proposed.

In regard to these last two findings, Walberg (1968a, 1969) has conducted a series of studies which shows that the classroom climate in high schools may be predicted from teacher and student personality. In particular, class structure appears to be related to both the teacher's

²⁸Mussen and Eisenberg-Berg (1977) present an impressive monograph on the roots of prosocial behavior in children, noting that mood level and reinforcement may play important roles as determinants of sharing and helping behavior. This assertion, however, is presented with caution, since it has not yet been objectively-tested in the natural environment, since no appropriate instrument has been developed.

affective reactions to classroom happenings, as well as the students' (Corey, 1973; McCandless, Castaneda, & Palermo, 1956; Trickett & Moos, 1973; Walberg, 1968b). A further result to come out of this area, where positive mood states are found to accrue from interpersonal interaction and teacher support, is that affective concern with the students as people, along with adequate content presentation, tends to increase the amount of material learned and retained.²⁹ Additionally, such classroom milieus were shown to induce feelings of security and interest in the students, indicating that these educational environments may promote personal risk-taking, which in turn, opens doors to other learning experiences which may not have otherwise been taken (Trickett & Moos, 1974). Conversely, there was found to be a pervasive mood of anger in students whose classrooms were characterized as being low in order, organization, and teacher involvement.

Clearly, these results indicate that the junior and senior high school instructor has a very real affect on the mood states of his/her charges. Such findings have very real and important implications for the future training of teachers and the devising of instructional methods. The mood affects of elementary school instructors, however, have not yet been determined since no state measure is currently

²⁹Further confirmation of the effects of mood on learning and retention has been provided by Bower (1981), who found that "recall" mood interacts with "learning" mood, thus indicating the presence of a mood state-dependent effect on memory processes.

available for that age group. It's hoped that an appropriate instrument may shortly be developed based on the research of the present investigation.

The last major area to be considered in this section is that of implications for clinical use. There is an extensive literature in the adult domain relating to mood states and fluctuations in psychiatric populations (e.g. see reference citations in Clyde, 1963; McNair, Lorr, & Droppleman, 1971b; Zuckerman & Lubin, 1965), as well as to the beneficial mood affects of clinical intervention (e.g. Haskell, Pugatch, & McNair, 1969; Lorr, McNair, & Weinstein, 1964; Lorr, McNair, Weinstein, Michaux, & Raskin, 1961; McNair & Lorr, 1964). Moreover, Zuckerman (1976) maintains that the daily assessment of mood states will solve the mystery of "disappearing admission symptoms" in psychiatric patients. As Rosenhan (1973) noted, "the insane are not always insane...they were sane for long periods of time...the bizarre behaviors {and cognitions} upon which their diagnoses were allegedly predicted constituted only a small fraction of their total behavior" (p. 254). Hence, by charting these behavior and mood fluctuations, the course of the disorder, as well as the affects of treatment and drugs on it, may be more clearly followed. And, if states are indeed more predictive of behavior than traits, then such assessment may eventually bring about the eradication of patient "labels" in favor of an emphasis on the ongoing states and behavior of the individual.

Just as this "mood charting" may be beneficial to "psychotic" and "neurotic" adults, such attention to state "may also be salutary for children with psychological problems. Spielberger et al. (1973) maintain that his STAIC is a useful indicator of transitory anxiety in children who are receiving counseling, and a countercheck on the effectiveness of specific behavioral procedures such as desensitization and counter-conditioning. Likewise, Yarrow (1979) asserts that effective preventive or therapeutic intervention cannot be given unless attention is also paid to the multiple affects that situation and state have on the immediate outcome of intervention:

We do not know a great deal about the kinds of preventive or therapeutic programs that are effective {for children}.... Research is needed in which theoretically meaningful interventions are attempted and their interactions with temperamental {mood state} characteristics are evaluated....Having identified both the environmental conditions and the temperamental {mood} characteristics and the ways in which they interact, we may be able to provide effective preventive or therapeutic conditions that will neutralize, reverse, or mitigate the damaging effects. (p. 955)

It would appear then, that in order for these interventions to be maximally effective, attention must also be paid to the immediate, as well as the mean levels of affect in the child. The present investigation into pre-adolescent mood structure is but a first step towards this end. As we have seen from a perusal of the adolescent and adult domains, the area of child state is rich in research and practical potential, nonetheless, in order for this potential to be

realized, an adequately-designed mood instrument must first be constructed.

B. Suggestions for Further Research

The immediate need, if any of the above theoretical or practical implications are to be realized, is the development of a simple, yet valid, instrument based upon the factors found for pre-adolescent mood structure. As Fiske (1971) maintains, in order "to advance the science of personology, intensive effort must be devoted to each major construct, to delineating it explicitly and systematically, and to creating measuring procedures conforming to the blueprints derived from such a conceptualization. Once we have created, tested, and refined these measuring procedures, we can begin to carry out empirical studies of the theoretical propositions involving that construct" (p. 14).

The present investigation was concerned with the first step of explicit and systematic delineation of mood structure in pre-adolescents. The second step, then, must be one of instrument creation, testing, and refinement in order to allow for the empirical study of the constructs purported. Additionally, this step would fulfill a prime requirement of factor-analytic research--that of construct validation (Comrey, 1973). This is an important consideration if, indeed, the measure is intended to be used in providing evidence of state change in children, an area

that has been sorely-neglected in the field of personality.

The ultimate test of any psychological discipline is the extent to which it increases our comprehension of human existence. The study of how children feel, how these moods are organized, and how their states affect behavior and cognition should be elemental to our goals of understanding humankind. If any further attention paid to childhood states augments our knowledge of people in general, then the present investigation may be considered at least a small contribution to a very important area of personology. As Edith Hamilton noted, "We differ in nothing more than in our capacity to feel... upon that degree the dignity and significance of each life depend." (cited in Wessman & Ricks, p. 251).

APPENDIX

Table A
Word Frequency Counts for Selected Mood Adjectives

Legend

American Heritage (A H)

Grade 3 frequency per 5 million words/S F I

S F I = Standard Frequency Index for grades 3-9 combined

- 90 = once per 10 words
- 80 = once per 100 words
- 70 = once per 1,000 words
- 60 = once per 10,000 words
- 50 = once per 100,000 words
- 40 = once per 1 million words
- 30 = once per 10 million words
- 20 = once per 100 million words

For example:

"absent-minded" at 0/34 indicates that this word occurred in grade 3 zero times per 5 million words vs once every 6 million words for grades 3-9 combined.

Rinaldo (R)

Underlined entries refer to items which are among the top 3,000 most commonly-used words for third-graders.

- 1 = occurrence within the first 1,000 words
- 2 = occurrence within the second 1,000 words
- 3 = occurrence within the third 1,000 words
- a = placement within the upper 500 of those 1,000
- b = placement within the lower 500 of those 1,000
- 1-5 = position within the first, second, third, fourth, or fifth 100 of the lettered group

For example:

"afraid" at 1_a5 indicates that this word occurs within the first 1,000 words, the first half of those 1,000, and in the fifth grouping of 100s (i.e., between numbers 400 and 499 of the most commonly-used third-grade words); "alive", on the other hand, at 3_a, indicates that this word falls within the upper 500 (a) of the third 1,000 most-used words (3).

All other entries refer to frequencies per 100,00 words, with some of these entries being modified by an additional number and letter. Such modifiers indicate the position of that word within the top 5,000 most frequently-used third-grade words.

For example:

"awful" at 78 indicates that this word occurs 78 times per 100,000, while "bashful" at 3_5b, signifies a word which occurs 3 times per 100,00, and which has a specific placement among the lower 5,000 of the most frequently-occurring words for third graders (i.e., between numbers 4500 and 4999).

Thorndike/Lorge (T L)

Frequency for grades 3-8 combined

- 1-900 = frequency of occurrence in 120 selected juvenile readings
- MJ = frequency of greater than 900 in 120 selected juvenile readings
- A = frequency of greater than 50 times per 1 million words
- AA = frequency of greater than 100 times per 1 million words

Weinman/Hagg (W H)

Spoken word count for seven year-old children

Number = frequency per 10,000 spoken words

Note. "No" indicates that a word was absent from the referenced source, while a blank entry denotes a phrase which was common to adult mood measures, but which was not included in any of the children's word corpora.

Phase 1

WORD RECALL TEST

Instructions read to the children for both Form A and Form B:

Hello, my name is Kar-La; and I go to school just as you do, only I go to the University.

The reason I'm here today is because I'm interested in finding out a few things about 3rd grade students. And, in order to learn about these things, I've made up a short test for you to take. I'll just pass these sheets out now, and then I'll explain what I'd like you to do.

When you receive a test please write your name on it, and circle the number giving your correct age. Also be sure to circle whether you're a boy or a girl....

Have you all finished? Good. Now when you look at the test you'll see a list of words numbered from 1 to 57. We are going to work through this list together.

I'll first read out the number, and then the word which follows it. What I would like you to do, is to write down two words which could describe feelings or moods you might have that are related to the word.

For example, when I look at the word "glad", I think of the words "happy" and "smiling", because if I were glad about something, then I'd be happy and I'd feel like smiling. So that's why I wrote those two feelings down after the word "glad".

Do you have any questions about what we'll be doing?...

If you don't know what a word means, then please leave it blank.

Okay, then we'll start with the first word, and you'll have $\frac{1}{2}$ minute to write down the two feelings which you think are related to it.

Number 1... Please write down two feeling words which you think are related to the word...

Parental Permission Slip

DEPARTMENT OF PSYCHOLOGY

THE UNIVERSITY OF ALBERTA
EDMONTON, ALBERTA
T6G 2E9

November 2, 1979

Dear Parents:

My name is Karla Schokman-Gates, and I am a graduate student at the University of Alberta working under the direction of Dr. E. Howarth (Professor, U. of A., Department of Psychology). My purpose in contacting you is to ask for permission to involve your child in a brief classroom study. This study will consist of a 20-30 minute activity wherein the students will be asked to decide whether or not they feel in a particular mood at that time. Each child will respond with a checkmark in either the "yes" or "no" column, to 60 mood adjectives printed on a confidential answer sheet which is to be computer scored. An example of a mood adjective phrase is: "Do you feel happy right now? yes no."

The information gathered from this session will be used to help determine the general mood patterns of children aged 7 to 12. Delinquent such states will greatly increase our knowledge of how feelings affect the behaviors of school-age children.

This research endeavor has been approved by the Edmonton Public School Board and the University of Alberta Department of Psychology. All responses made by the children will be kept in the strictest confidence. If you have any questions, please contact me at 432-5274 (days) or 462-0094 (evenings). Your cooperation in this project is greatly appreciated.

Please sign the bottom of this page and have your child return it at your earliest convenience.

I, _____, agree to have my child, _____, participate in the above-noted research.

I, _____, do not agree to have my child, _____, participate in the above-noted research.

Thank you very much for your time
and consideration!

K. Schokman-Gates

Note. Due to binding requirements, this slip was reduced from the original yellow 8½" by 11" format.

Hello, my name is Kar-La', and I go to school just as you do, only I go to the University.

The reason why I'm here today is because I'm interested in finding out a few things about elementary school children, and, in order to learn about these things, I've made up a questionnaire for you to fill out. I'll just pass these sheets out now, and then I'll explain what I'd like you to do.

When you receive a questionnaire, please write your name on the top of the separate answer sheet; the one that looks like this. Also be sure to put down your age and whether you're a girl or a boy....

Have you all finished writing down your name, age, and sex? Good.

Now look at the instructions at the top of the orange questionnaire. The instructions say: "On this page are some statements which girls and boys often use to describe how they feel. These statements are numbered, and there is one statement on each line...." Look at statement 1 on this page. It says "Right now I feel good..... Yes No ". Now look at the #1 on your answer sheet. If you feel good right now, please fill in the "Y" or "Yes" box next to this number just as I am doing on this example sheet. If your answer is "No", then fill in this "N" box. Do you understand how to mark your answer? Good.

Now go to statement 2 and do the same thing. Continue going through each statement by reading it silently to yourself and then marking either the Y ("Yes") box or the N ("No") box. We want your true feelings, so mark the first answer you think of after reading each statement.

You may now begin.

After 7 minutes say:

Almost everyone has now started on page 2 (or 3 or 4). If you are not on page 2 (or 3 or 4) yet, please try to work a little faster.

At end of test say:

Now please look back over your answer sheet to make sure that you have answered every statement. Also, make sure that your age and sex are marked on the answer sheet.

Do not write on this form _____

INSTRUCTIONS: On this page are some statements which girls and boys often use to describe how they feel. These statements are numbered, and there is one statement on each line. Please read each statement carefully, and decide whether you feel that way right now. We want your true feelings, so mark the first answer you think of after reading each statement. An answer sheet is provided inside this form.

1. Right now I feel good. - - - - - Yes No
2. Right now I feel active. - - - - - Yes No
3. Right now I feel afraid. - - - - - Yes No
