Stocking levels for white spruce: How many trees do we need to establish?

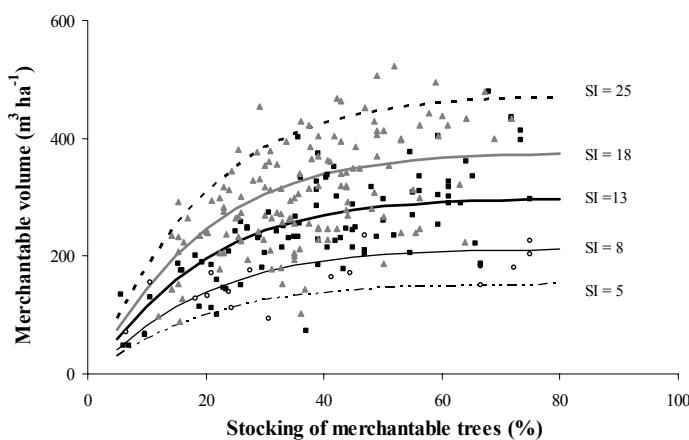

ZHILI FENG, KEN J. STADT, AND VICTOR J. LIEFFERS

In many parts of Canada, provincial regulations require juvenile surveys to prove that forests are re-established; in Alberta a stocking survey (using a grid of 10m² plots) must be done by year 8 and performance survey by year 14. Targets for these surveys, however, were mostly established by expert opinion. We evaluated the linkage between spatial pattern and stocking; and stocking, tree mortality and final yield of white spruce in mixedwood stands.

Data were from 709 stands, aged 7 to 150 years, including juvenile and mature permanent sample plots, and juvenile survey data.

Findings were:

- 1) The relation between stocking and density is not a straight line and is influenced by the spatial pattern of the trees, which can be easily estimated from counts of tree in regeneration survey plots.
- 2) In regenerated stands, ingress of natural spruce often overwhelmed the regular planting pattern, creating clumped distributions in many stands.

3) In mature permanent sample plots, only 30-40% stocking of spruce in 10 m² plots was needed to achieve full yields of unmanaged stands.

4) Mortality rates for planted spruce varied from 0.1-0.8% year⁻¹, between 7 and 23 years and 1.7-3.3% per year for mature stands. For rotation-length predictions, 0.7% per year is likely an average mortality loss.

5) Between 7 and 23 years, the mortality rate for the tallest “crop tree” spruce measured in each 10m² plot, was similar regardless of its size.

Implications:

1) At age 14, a well-dispersed planting pattern of 1200 stems per ha would have 85% stocking. A 0.7% per year average mortality rate until age 120, would leave 60% stocking; this is higher than the 30 to 40% stocking needed to reach full yield. However, if mortality rates were 1.5%, it would be approximately the correct level of stocking. A better grasp on mortality rates is for spruce in mixedwoods is required.

2) Since crop trees in juvenile 10m² plots had similar rates of early mortality regardless of size, a minimum height standard for trees to be acceptable can only be viewed as a performance measure, rather than an indicator of future survival.

Funding was provided by the Mixedwood Management Association, West Fraser, Weyerhaeuser and NSERC.
