ABSTRACT

This thesis deals with two subjects: Ring opening of cyclopropylcarbinyl radicals as a synthetic methodology, and synthetic studies related to Calicheamicinone.

In the first chapter, cyclopropylcarbinols 8a and 8b (Scheme A), which are accessible by a number of routes, are converted into the corresponding radicals 9a and 9b, respectively. These radicals undergo peripheral ring-opening of the cyclopropyl substructure to afford substituted cycloalkenes 10a and 10b. The whole sequence represents a general method for attaching alkyl, and substituted alkyl groups to an existing cyclic structure and it can often be carried out with predictable stereo- and regiochemical control.

SCHEME A

OH
$$R = R'$$

This new methodology was then combined with conventional radical ring closure for the preparation of benzofuran derivatives needed for evaluation as inhibitors of leukotriene biosynthesis.

In the second chapter, synthetic studies related to the aglycon portion (calicheamicinone) 105 of the newly-discovered antitumor agent calicheamicin $\gamma_1{}^I$ is described.

The central core of 105 was constructed by a Diels-Alder cycloaddition involving the novel diene 218 and the known dienophile 219 (Scheme B). Further elaboration of the resulting cyclohexanone 237a led to the advanced intermediates 282a and 282b.

In addition to describing our own synthetic work, the second chapter reviews the published synthetic achievements of other researchers in this field.

ACKNOWLEDGEMENTS

I express my gratitude to Professor D.L.J. Clive for his advice and encouragement throughout the course of my studies, and for his assistance in the preparation of this manuscript.

The efforts of the technical staff in the Chemistry Department are much appreciated and I thank particularily the members of the NMR group for training on the high-field NMR spectrometers and for valuable practical help.

I thank my friends and coworkers for their companionship and support, and for helpful discussions.

I gratefully acknowledge generous financial support in the form of scholarships from the Natural Sciences and Engineering Research Council of Canada, the Alberta Heritage Scholarship Fund, the F.C.A.R. Fund (Quebec), the Government of the Province of Alberta, the University of Alberta, and the Alberta Heritage Fundation for Medical Research.

Finally, I thank Christine, for her patience, support, and understanding throughout the course of this work.

SYNTHETIC APPLICATIONS OF RING OPENING OF CYCLOPROPYLCARBINYL RADICALS, AND SEQUENTIAL RADICAL RING CLOSURE-RADICAL RING OPENING FOR PREPARATION OF BENZOFURANS

I. INTRODUCTION

Radical ring closure has been investigated intensively¹ in the last few years and is now an important method in organic synthesis. However, the synthetic applications of the reverse process, i.e. radical ring opening, have not yet been widely appreciated. This situation is surprising because the physical organic chemistry of radical ring opening is a very well-studied area.

Most of the reported² measurements involve small rings because the opening of larger rings does not usually occur at an adequate rate,^{2,#} unless substituents are present that stabilize the product radical. Extensive kinetic studies have been made for the parent system over a range of temperatures,^{4,5a} and kinetic data are also available for cyclopropylcarbinyl systems carrying substituents such as methyl,⁵ ethoxycarbonyl,^{5b} and phenyl.⁶

The parent system (Equation 1) has a rate constant for ring opening of $10^8 \, \text{s}^{-1}$ at $25 \, ^{\circ}\text{C.}^{4,5}$ The reverse process is much slower, the rate constant being about $10^4 \, \text{s}^{-1}$. It should be noted that the absolute and relative values^{4,5} of these rate constants can be influenced profoundly by the substitution pattern.

[#] Fission of the C(9)-C(10) bond in the 9-decalinoxyl radical is fast but reversible (reference 3).

The substitution pattern also plays a role in the preferred regiochemistry of opening,⁷ and the effects can be understood in terms of frontier molecular orbital theory. For example, in the reaction shown by Equation 2, the SOMO interacts preferentially with the LUMO of the C(1)-C(3) bond because the corresponding orbital of the C(1)-C(2) bond is raised in energy by the attached methyl groups, which are electron-releasing.

$$\begin{array}{c} \text{Me} \quad \text{CH}_2 \\ \text{Me} \quad \text{3 CH}_2 \end{array} \qquad \text{Eq. 2}$$

In disubstituted cyclopropanes, the relative geometry of the substituents can determine the regiochemistry of the radical ring opening because reaction will tend to take place through that conformation in which nonbonded interactions are minimized. Radical 1 (M = metal), for example, gives 3 (R^1 = OM, R^2 = Me or R^1 = Me, R^2 = OM) (Scheme 1). Clearly, conformation 2, rather than 4 is involved in the process.^{7b,8,#}

Some types of cyclopropylcarbinyl radical have been used in mechanistic studies## as radical clocks.

[#] The alternative to 4, in which OM and attached Me are interchanged, is also disfavoured by non-bonded interactions.

^{##} For a review on free radical clocks, see reference 9.

Recently, radical addition to vinylcyclopropanes has become an active area of research, 10 and typical applications are summarized in Equations 3^{10b} and $4.^{10i,11}$

When the cyclopropane is fused to another cyclic structure stereoelectronic factors can be important in determining the regiochemistry of ring opening, 12,13,14 and the cyclopropyl bond that breaks is the one that overlaps best with the SOMO, as shown by Equations 5 and 6.

Although most physical chemical work has been done with three-membered rings, some rate measurements have been made for other ring sizes. Rate data are available for cyclobutylcarbinyl radicals (Equation 7),^{2,15} and there is information on the regiochemistry^{15a,16} and stereoelectronic features of the process. Very few synthetic applications are known; those we are aware of are summarized in Equations 8¹⁷ and 9.¹⁸

$$\frac{4.5 \times 10^{2} \text{ s}^{-1}}{(25 \text{ °C})}$$
 Eq. 7

Five-membered rings do open, but only if the resulting species is appropriately stabilized, 19,20 as shown in Equation 10.

The opening of cyclopropyl- and cyclobutyl-carbinyl radicals in which the ring is fused to a cyclic structure has very rarely been used in synthesis^{17,21} (Equation 11), but the following work, and spirocyclizations of the type shown in Equation 12,²² are the first attempts to develop the synthetic potential of such reactions.

Very recently, a further example has been reported (Equation 13).²³ It should also be mentioned that radical opening of epoxides^{24,25} and aziridines²⁶ has been studied. These reactions appear to have some synthetic utility ^{25a,b,f,26} and the epoxide case is useful for detecting radicals.²⁷

Finally, the opening of cyclopropylcarbinyl radicals is believed to be involved in a number of biochemical transformations.^{28,#,##}

[#] Cyclopropylaminyl radicals may be involved in mechanism-based enzyme inhibition by cyclopropylamines: reference 29.

^{##} Epoxides may be involved in the biosynthesis of Rifamycin S: reference 30.

II. RESULTS AND DISCUSSION*

(A) SYNTHETIC APPLICATIONS OF RADICAL RING OPENING

The sequence involved (Scheme 2) in the use of radical ring opening for the introduction of alkyl groups with stereocontrol, can be divided into three main stages. First, ways had to be selected to prepare the cyclopropanes and, preferably, the stereochemistry of the latter should be controlled $(7\rightarrow8a \text{ or } 7\rightarrow8b)$. Second, an appropriate method had to be found that would allow introduction of a group adjacent to the cyclopropane that will serve as a radical precursor. Finally, it was necessary to determine what factors (i.e. experimentals conditions and/or substitution patterns) favor opening of the cyclopropane moiety in the desired sense to provide the alkyl substituted cycloalkenes $(9a\rightarrow10a \text{ or } 9b\rightarrow10b)$.

1) Cyclopropanation

In this work, several cyclopropanation processes were used (Table 1, page 13-15). We first evaluated the classical Simmons-Smith reaction, as it can be done stereoselectively³¹ using allylic alcohols. Indeed, there are many reports where treatment of cyclic allylic alcohols leads to formation of cyclopropyl alcohols in which both cyclopropane and hydroxyl group are syn to each other. The hydroxyl group present on the molecule also serves as a precursor to a radical.

We arbitrarely used the Zn/CH₂I₂/ultrasound system for the conversion of decalin alcohols 16a and 17a to 16b and 17b, respectively, and the Zn(Cu)/CH₂I₂ reagent for conversion of steroid 19b→19c (Table 1). It will be noted that in cases where a readily accessible allylic alcohol does not have the desired stereochemistry, Mitsunobu inversion³² can be used to make the necessary correction. The overall result is that both stereoisomeric cyclopropyl derivatives of an alkene precursor are accessible readily, as shown by preparation of decalin 17b (stereoisomer of 16b) and estrone derivative 19c (stereoisomer of 18c).

A very mild version of the Simmons-Smith reaction was reported recently in which zinc is replaced by samarium.³³ As this method was also suitable for making alkyl-substituted cyclopropane derivatives, we used it for the preparation of methylcyclopropane **20b** (45%, 69% based on conversion) by treatment of a cold (-78 °C) solution of **20a**# in THF with 1,1-diiodoethane and samarium amalgam, followed by slow warming to room temperature.

[#] Compound 20a was prepared in four steps from 2-cyclopentene-1-acetic acid (see experimental).

Not unexpectedly, the nature of the samarium metal, i.e. the source and/or quality and/or mesh size, seemed to be of great significance, but we were eventually able to conduct the cyclopropanation cleanly and in reproducible yield.

Another means of generating cyclopropanes is by dichlorocarbene addition.³⁴ Compounds 14b and 15b were conveniently made in 71% and 73% yield, respectively, by treatment of a solution of 14a or 15a in chloroform with 50% w/w sodium hydroxide and a phase transfer catalyst. In both cases, yields were substantially higher when the reaction was stopped short of completion. The dichlorocarbene addition is reported to occur with stereochemical direction by the hydroxyl and the selectivity is thought to arise by hydrogen bonding of the alcohol to the active reagent. On this basis, the single product isolated in each case was assigned the stereochemistry indicated, where the cyclopropane is syn to the hydroxyl.

Corey et al.³⁵ reported an example where a three membered ring is generated by intramolecular carbene delivery and we applied this method to the preparation of 13d. Acylation of cyclohexen-1-ol with a protected form of α-diazoacetyl chloride (TsNH-N=CHCOCl), followed by treatment in situ with triethylamine gave the desired α-diazoester 13b in 70% yield. Slow addition of this material to a refluxing solution of a copper(II) catalyst in toluene gave the desired cyclopropane lactone 13c (88%) with of course, complete stereocontrol. The latter was then converted (88%) to hydroxyamide 13d using Me₂AlNMe₂.³⁶

A different approach to a cyclopropane of predictable geometry, this time based on phosphonate chemistry, was used to construct the sugar derivatives $21b^{37}$ and $22a.^{38}$ In both cases, an epoxide of appropriate stereochemistry was available in a few trivial steps from an α -methyl glycoside. Sugar epoxide 21a was treated with the ylid derived from triethyl 2-phosphonopropionate. The ylid attacks at C-2 to give a pentacoordinate species as an intermediate³⁹(Equation 14). This species collapses to afford conformers 24 and 25. In 24, the interaction between the electrons on the ring oxygen and those in the π cloud of the enolate ion is disfavored vis a vis 25. Ring closure from the latter then leads to the desired cyclopropane derivative as a single isomer.

It is reported³⁸ that in the case of **21a** many efforts were made to convert it into cyclopropane **22a** under a wide variety of conditions. However, with all the solvents and temperatures tried, the reaction proceeded in poor yield (1 to 17%) unless it was conducted in dioxane at 160 °C in a special stainless steel pressure vessel.³⁸ Those conditions were most inconvenient for a

multigram reaction, and therefore, we sought of an alternative whereby dioxane (an ethereal solvent) would be replaced by a solvent of similar nature but with a boiling point high enough that the use of a pressure vessel could be avoided. When the reaction was conducted on a 20g scale in triglyme at 140 °C, 22a was obtained in 45% yield. This result compares favorably with the yield reported (45%) in the literature, and requiring the use of a pressure vessel.

Enones can also serve as substrates for direct cyclopropanation. Conversion of cyclohexenone 11a or the estrone derivative 12a# to the cyclopropane esters 11b and 12b was achieved using sulfur ylide chemistry (Me₂S=CHCO₂Et).⁴¹ The reaction proceeds by conjugate addition of the reagent to the enone to produce an enolate which displaces the Me₂S+ group intramolecularly to give a cyclopropane bearing a carboethoxy substituent. The non-substituted version of 12b, i.e. 18b, was obtained very similarly using CH₂=S(O)(CH₃)₂. In all three examples, the ketone was then reduced to the corresponding alcohol 11c, 12c, and 18c, in order to provide the group that will serve eventually as the radical precursor. Of course, the procedure based on enones cannot be adjusted at will to place the cyclopropane on either face of the molecule.⁴²

Clearly, a wide variety of cyclopropanation conditions are available and therefore it is likely that one can be found that is compatible with functional groups present in a given molecule and allows the cyclopropanation to be

[#] Compound 12a was synthesized in five steps from commercially available estrone, following a literature procedure. 40

effected with stereocontrol. Mitsunobu inversion allows access to both isomeric alcohols and therefore to both isomeric cyclopropane derivatives. Moreover, assymetric cyclopropanation⁴² is also available for construction of molecules in optically pure form, but we did not examine this possibility.

2) Introduction of the radical precursor

The second stage of the process shown in Scheme 2 involves introduction of the radical precursor. In most case, this was achieved by converting the alcohol to a phenylseleno derivative (Table 2, page 27-29).

At first we used the standard method⁴³ whereby tributylphosphine is added to a solution of the alcohol and phenylselenocyanate in THF. However this method was not satisfactory as the reactions would often not go to completion. The use of a large excess of both reagents made no significant difference. We eventually found that by slowly adding a solution of phenylselenocyanate in THF to a solution of the substrate and tributylphosphine in the same solvent, very significant improvements were achieved, and we now prefer this procedure. In other cases, we have found

that replacement of the hydroxyl by the selenium unit did not always involve clean inversion of stereochemistry, but this is of no consequence since both epimers at the selenium-bearing carbon afford the same radical.

Although the conversion of a hydroxyl to a selenide works very nicely, purification of the latter by flash chromatography is necessary to remove the phosphine byproducts and this is not suitable for a large scale work. Conversion on a multigram scale of 14b to 14c, was achieved therefore by a more convenient two step procedure.#

Alcohol 14c was cleanly converted (80-90%) to the corresponding tosylate as a white crystalline compound which can be recrystallised easily. The tosylate can be kept for months in the refrigerator, but if it is left standing on the bench for a day or two, it decomposes to a black tar. Nucleophilic displacement of the tosylate with 1.05 equiv of PhSeNa in THF-HMPA⁴⁵ afforded the desired selenide 14c in 91% yield after simple filtration through a short pad of silica to remove polar material.

A problem often encountered in the preparation of selenides is the necessity of removing diphenyl diselenide which invariably forms during the process. This problem can sometimes be serious if the selenide is non-polar and co-runs with diphenyldiselenide on silica gel. Purification is then very difficult if not impossible. This problem was encountered on many occasions during the course of this project, but we have been able to find a general solution.

[#] The conversion of 14a to 14d has been submitted for publication, see reference 44.

Treatment of the crude material with sodium borohydride (see experimental) converts diphenyldiselenide to PhSeNa without affecting the selenide to be purified. Once the yellow coloration characteristic of diphenyl diselenide has disappeared, the solution is treated with bromoacetic acid which converts the PhSe- anion to (phenylseleno)acetic acid; the latter is conveniently removed from the selenide by extraction into aqueous base.

An obvious alternative to selenides as radical precursors is the use of thiocarbonyl derivatives. However, because the selenides could be prepared easily and the selenide unit served its role of radical source very well, 46 (see later) we did not examine the alternative thiocarbonyl thoroughly. In the few examples we tested, i.e. 26-28# we found that the traditional thermal deoxygenation 48 in refluxing benzene 44 was unsuitable, but we did not try reaction at a low temperature using the triethylborane method. 50

26 X = Imidazolyl

27 X = OPh

28 X = SMe

[#] With the standard preparations given in reference 47 and 48, the yields of 26, 27, and 28 were 76%, 75%, and 45% respectively.

^{##} One of the problems, we encountered was extensive formation of olefinic material, tentatively assigned as structure 29 (see page 20). However, for a very successful related use of the classical Barton deoxygenation, carried out in refluxing benzene, see reference 50.

The carbohydrate examples were dealt with differently and neither selenides nor thiocarbonyl groups were used as the radical precursor. Close inspection of sugar 21b (=23b) revealed that it could be elaborated into derivatives in which a radical precursor could be placed either on the right or on the left of the cyclopropane moiety. In principle, therefore, opening of the cyclopropane could be achieved from either side.

The diol moiety of 23b (=21b) was released (H₂ / Pd/C) and protected as the diacetate (acetic anhydride, pyridine). Then, acetolysis of the methyl glycoside followed by treatment of the resulting anomeric acetate with bromotrimethylsilane⁵¹ gave the required anomeric bromides 23c in good overall yield (> 74%). (hydrogen bromide in acetic acid was unsatisfactory in this case.) From this radical precursor, the possibility of opening the righthand side of the cyclopropane moiety arises. On the other hand, treatment of the same material (i.e. 21b) with NBS in carbon tetrachloride led to the bromobenzoate derivative 21c, in which the benzoate unit will serve as the radical precursor. This process allows the possibility of opening the lefthand side of the cyclopropane moiety.

Finally, the dimethyl analog 22b,* which is readily accessible from 22a, was also converted (71%) to the bromo benzoate 22c using NBS in carbon tetrachloride.⁵²

[#] Prepared from 22a according to the literature procedure. 38

3) Generation of the radical and ring opening

The third stage of the process shown in Scheme 2 involves generation of a radical at the carbon bearing the hydroxyl. The conditions used for generating the radical and opening of the ring were determined by the nature of the radical precursor and by the substituents on the cyclopropane moiety. In most cases, where a strong electron-withdrawing group is present (i.e. CO₂Et in the case of 11d, 12d, and 23c or CONR₂ in the case of 13e), addition of stannane and initiator (each in one portion) to a solution of the substrate in refluxing benzene, was employed successfully. In no case did we observe formation of products resulting from ring expansion or from simple reduction without ring opening. It will be noted that the process represents in these examples a radical equivalent of an Ireland ester-enolate rearrangement (Scheme 3).

In contrast, studies with unsubstituted cyclopropanes like decalin 16c showed significant amounts of ring expansion product under these conditions. Indeed, when radical ring opening of 16c was conducted in refluxing benzene, the 1 H NMR spectrum of the product mixture showed a doublet of triplets at δ 5.28 and 5.51. The signals correspond to the two vinylic hydrogens of 16d, which is a known compound. However, the material was contaminated with ca 55 mol% of an olefinic side product tentatively identified as 29 on the basis of the high multiplicity of the vinylic hydrogens which resonate at δ 5.55--5.72. Repeating the reaction at higher temperature, and/or adding the stannane and/or substrate slowly did not result in any improvement.

25

The fact that ring expansion is a competing process here is not surprising as the decalin system 16c has a feature which represents a very unfavorable case. Not only is the cyclopropane moiety unsubstituted which, as we will see later, makes ring expansion more favorable, but the desired process leads to a primary radical as an intermediate whereas ring expansion (internal homolysis) generates the much more stable tertiary radical. In most cases competition will be between primary and secondary radicals for peripheral and internal homolysis, respectively and, therefore, inhibition of ring expansion should be easier.

It was eventually found that, by conducting the reaction at lower temperatures (0 °C), an 84% yield of the desired product 16d, contaminated by less than 5% of ring expansion product 29, could be obtained. From now on all the reactions involving substrates containing a cyclopropane lacking an electron withdrawing substituent were conducted at low or moderate temperatures (-20 °C to 25 °C). The procedure consists simply of irradiating a cooled solution of the substrate and stannane with a domestic sunlamp.

Estrone derivatives 18d and 19d were also treated with stannane at low temperature, and under these conditions a good yield (72%) of the desired methyl substituted cyclopentene derivatives 18e and 19e, respectively, were obtained along with some (ca 14%) ring expansion product 18f (=19f). These two examples clearly show that, by using the same starting material, the methodology allows formation of a cyclopropane on either face of the molecule and, after radical ring opening, leads to isomers whose newly introduced substituents are on opposite faces.

It is appropriate at this point to comment on the ring expansion product 18f. The latter had to be unambiguously identified by comparison with an authentic sample. It was decided that the effort spent in preparation of an authentic sample, would serve at the same time to study the properties of a novel titanium reagent that was being developed in our laboratories.⁵³ The reagent, which is made from C₈K (2 moles) and titanium trichloride (1 mole), had been successfully used for the coupling of sensitive dicarbonyl compounds to give olefins⁵³ (McMurry coupling), and we wanted to test the feasibility of the process whereby a diol would be converted to an olefin.

We felt that this process should work since a diol derivative is quite likely formed as an intermediate in the dicarbonyl coupling.

Therefore, the precursor of olefin 18f would be the diol 30 and the latter is readily accessible in four steps from methyl estrone.⁵⁴ We were pleased to find that treatment of diol 30 with C₈K and titanium trichloride in refluxing diglyme gave a 92% yield of the expected olefin 18f, and that its ¹H NMR and ¹³C NMR were identical to those of the olefinic byproduct obtained in the radical ring opening sequence. Hence the structure assigned to 18f was confirmed.

Whereas ring expansion competes to a certain extent in the case of unsubstituted cyclopropane derivatives, the presence of a methyl substituent on the cyclopropane moiety seems to suppress the formation of ring expansion products, as shown with selenide 20c. Treatment of the latter with stannane at a moderate temperature (25 °C) gave the desired ethyl cyclopentene product 20d (65%) with no evidence of a ring expansion product.#

[#] Compound 20d was slightly contaminated with 4% of unidentified byproduct.

In the case of selenide 14c, where two chlorine substituents are present on the cyclopropane, the reaction was also conducted at low temperature (-10 °C) and the desired dichloromethyl cyclohexene 14d was obtained in excellent yield (> 90%). Maintenance of a low temperature in this case also serves to inhibit dechlorination. With the analog 15c, we deliberatly reduced the initial ring-opened product further so as to obtain the monochloride 15d (92%).

Although in most cases we have used triphenyltin hydride, we found it was sometimes preferable to use the tributyl analog. In some examples separation of the tin byproducts is easier with one or the other of the stannanes. In the case of decalin 16c, the optimum conditions called for use of tributyltin hydride. This is a poorer hydrogen donor⁵⁵ and its use served to inhibit more efficiently the formation of cyclopropane 31.

All the conditions developed to generate the radicals, were suitable for use with selenides. In the case of the carbohydrates 21c and 22c, the radical precursor is a benzoate and therefore a photochemical method was used. 56 The method consists of irradiating a solution of the substrate, N-methylcarbazole and magnesium perchlorate in THF-water with a high pressure mercury lamp. Under these conditions, a radical is generated at the carbon bearing the benzoate, and the ring-opening process takes place as with

the previous examples. The mechanism of the photochemical process is shown in Equation 15.

ROCAr +
$${}^{1}D^{+}$$
 ROCAr + D^{+} D

Eq. 15

D = Electron donor sensitizer

XH = Solvent
 ${}^{1}D^{+}$ = Photoexcited sensitizer

ROCAr + D^{+} ROCAr - $ArCO_{2}H$

Using 21c as the starting material the desired ring-opened product 21d was obtained in excellent yield (86%). It should be noted that this conversion, combined with the previously discussed conversion of anomeric bromides 23c to 23d, serves to illustrate the fact that it is possible to prepare a carbohydrate cyclopropane flanked on either side by a potential radical precursor. Hence regiochemical control is possible, and the substituents resulting from cyclopropane opening can be placed at one or other of two sites.

With the corresponding dimethyl cyclopropane analog 22c, the expected products 22d and 22e (1:1 ratio) were obtained in 67% yield. The fact that two products arise has nothing to do with the ring opening process itself but is simply due to the fact that during the process, a tertiary radical is formed. Under the photochemical conditions used, tertiary radicals readily disproportionate⁵⁶ to give, in this case, isopropyl and isopropenyl derivatives 22d and 22e. (Equation 16).

It should be noted with this last example that no ring expansion is observed even though no strong electron-withdrawing substituent is present on the cyclopropane. This outcome was expected since the temperature of the reaction mixture was low enough (room temperature) to inhibit the competing processes. Moreover, in contrast to the procedure based on stannane chemistry, the photochemical method is compatible with the presence of a bromine atom. Indeed, in the transformations we have just discussed, i.e. $21c\rightarrow 21d$, and $22c\rightarrow (22d+22e)$, the bromine atom that was present was left untouched.

Compound 17c was the only example we found that did not undergo ring opening (see experimental) under our standard conditions, but gave instead 32 as the major (> 80%mol) compound (Equation 17). We attribute⁵⁷ this to the fact that the conformation of the molecule results in poor overlap between the radical center and all the cyclopropane carbon-carbon bonds.

Finally, before concluding our studies on cyclopropane ring opening, we decided to repeat reactions that were originally achieved by photochemical initiation (sunlamp) by using a newly introduced method⁵⁰ which consists of treating a solution of the substrate and stannane at room temperature with triethylborane and a controlled amount of air. The role of triethylborane is to serve as a radical initiator by the mechanism depicted in Equation 18.

$$Et_3B \xrightarrow{O_2} \left[Et_3BO_2\right] \xrightarrow{} Et_2B \xrightarrow{} O \xrightarrow{} O \cdot + Et \cdot \xrightarrow{R_3SnH} R_3Sn \cdot + EtH$$

$$Eq. 18$$

In the three cases we examined, i.e with the dichloro derivatives 14c and 15c and with the decalin 16c, the reaction performed under these new conditions worked very well (see experimental) and so this method represents a convenient alternative to photochemical initiation.

TABLE 2^a

Introduction of the radical precursor and ring opening step

(xxv) as in (iv); >80%. aWhere stereochemical assignments are tentative, this fact is indicated in the experimental section.

4) Conclusion

The above results show that radical ring opening of cyclopropane carbinols is a general method for attaching alkyl and substituted alkyl groups to an existing cyclic structure and it can often be carried out with predictable stereo- and regiochemical control. Where the non-bridgehead carbon of the cyclopropane carries a strongly electron-withdrawing group the ring opening can be done at the reflux temperature of benzene and proceeds efficiently. However, in the absence of such electron-withdrawing groups a low temperature is best used in order to suppress ring expansion. Like many radical-based methods the procedure is compatible with a range of functionality and the required radicals can be generated by a number of different and complementary methods.

[#]But cf. reference 22

(B) SEQUENTIAL RADICAL RING CLOSURE--RADICAL RING OPENING: USE IN THE PREPARATION OF BENZOFURANS

Encouraged by the above results, we decided to combine the methodology with conventional radical ring closure in such a way that benzofuran derivatives would be readily accessible. The ultimate goal was not necessarily to provide a new route to benzofurans, but rather to evaluate the feasibility of the radical closure-ring opening process on a system which, at the same time, would give access to compounds we were interested in at the time (for evaluation as inhibitors of leukotriene biosynthesis).⁵⁸

1) Preparation of benzofurans

The radical closure-ring opening sequence, involves Mitsunobu coupling of o-bromo phenol 33 with the functionalized alcohol 34 (Scheme 4).

SCHEME 4

Scheme 4. Reagents and conditions: (a) DEAD, Ph₃P, THF, -20 °C to rt, 1 h, 33%; (b) Bu₃SnH, Et₃B, hexane, 35 °C, 24 h, 67%.

Treatment of the coupled product 35 with stannane would generate an aryl radical which should undergo a very facile 5-exo ring closure to give an intermediate in which the newly formed radical is adjacent to the cyclopropane moiety. Therefore, ring opening should take place and, after reduction of the ring-opened radical intermediate by stannane, the tricyclic product 36 would be obtained.

The required alcohol 34 was synthesized as follows (Scheme 5). Conversion of the known olefin 37⁵⁹ to the corresponding epoxide using a wide variety of epoxidizing agents (*m*-chloroperbenzoic acid, Davis's reagent, hydrogen peroxide in benzonitrile) proceeded with little stereoselectivity⁶⁽⁾ and it was therefore desirable to devise a better route. A variety of selenenylation conditions were then attempted, and it was eventually found that treatment of the same olefin 37 with benzeneselenenyl bromide and potassium acetate,⁶¹ provided much greater facial discrimination. Indeed, this procedure afforded the selenoacetates 38 in 65% yield after purification.

SCHEME 5

Scheme 5. Reagents and conditions: (a) PhSeBr, AcOK, AcOH, 2 h, ca 65%; (b) 30% aqueous H2O2, pyridine, THF-CH2Cl2, 2 h, ca 93%; (c) EtONa, EtOH, 2 h, 79%.

The major component [AcO and C(7) syn] constituted 85 mol% of the mixture (1 H NMR). Oxidation of selenides 38 with hydrogen peroxide was followed by selenoxide elimination to afford the allylic acetate 39. This was largely [>85 mol% (1 H NMR)] one isomer. Deacetylation (sodium ethoxide) and purification of the crude material gave the desired alcohol 34 (v_{max} 3450, 1720 cm⁻¹) as a single isomer. The 1 H NMR spectrum showed two sets of olefinic signals at δ 6.25 (dd, J = 9.8. 3.8 Hz) and δ 5.75 (dd, 9.8, 5.2 Hz). The carbinyl hydrogen resonated in the expected region [i.e., δ 4.3 (m)] and the signals corresponding to the hydrogens on the cyclopropane ring all overlapped in the δ 1.8 to 2.1 region.

In order to determine the stereochemistry of the substituents on the ring, the alcohol was converted to its 3,5-dinitrobenzoate derivative and submitted for X-ray analysis (Figure 1).# It was found that the hydroxyl group and the cyclopropane are syn to each other and that the ester group, not unexpectedly, is in the exo configuration

The presence of the ester on the cyclopropane was dictated by our wish to have a carboxyl group in the final product, and had the added advantage of controlling the regiochemistry of cyclopropane opening.⁶²

Only low angle diffraction data were collected.

Figure 1. X-ray crystal structure of the 3,5-dinitrobenzoate derivative of 34

With the alcohol 34 in hand, its coupling with phenol 33 was conducted and led to the desired product 35 in 33% yield (Scheme 4). Although, the yield was poor, no optimization was attempted as the coupled product 35 served only to test the free radical conversion to 36. Treatment of 35 with stannane and triethylborane in the presence of air⁵⁰ gave the desired tricyclic compound 36 in 67% yield. Since the reaction proceeded satisfactorily, the sequence was repeated using the more substituted phenol 45 (Scheme 6).

SCHEME 6

Scheme 6. Reagents and conditions: (a) EtCOCl, AlCl₃, 2 h; then dilute HCl, 47%; (b) Zn(Hg), conc HCl, reflux, 1.5 h, 88%; (c) SO₂Cl₂, ether, 1.5 h, 70%; (d) Br₂, AcOH, 45 min, *ca* 92%; (e) TBDMSCl, imidazole, DMF; (f) BBr₃, CH₂Cl₂, -78 °C, 82% overall.

The choice of the substituents on the latter was made in such a way that the benzofuran derivative eventually produced, would ressemble other previously studied benzofurans,⁵⁸ which had been found to inhibit leukotriene biosynthesis.

Compound 45 was synthesized as follows: (Scheme 6). Friedel-Crafts acylation of dimethoxybenzene⁶³ with propionyl chloride gave propiophenone 41, which was reduced with amalgamated zinc in concentrated hydrochloric acid⁶⁴ to afford the corresponding propylphenol 42. Chlorination (sulfuryl chloride) and then, bromination (bromine/acetic acid) led to 44⁶⁵ in good overall yield (63%). Silylation followed by deprotection of the phenol (boron tribromide) gave 45 (82%), which is suitably set up for the coupling step.

Mitsunobu coupling of 45 with alcohol 34 gave the desired product 46 in very good yield (80%) providing that activation of the alcohol was done at -30 to -20 °C, and not at a higher temperature, in which case elimination of the hydroxyl group is a competing process (Scheme 7).

The stereochemistry of 46 (and also of 35) is a tentative assignment based on the assumption that inversion occurs. Desilylation (TBAF) of 46, and treatment of 47 with stannane, under the conditions used for 36, led to the desired product 48 (43%), together with a minor byproduct 49 (18%). Evidence in favor of such an assignment for 48 was obtained on the basis of the following considerations:

SCHEME 7

Scheme 7. Reagents and conditions: (a) DEAD, Ph₃P, THF, -30 to -20 °C, 2 h; (b) TBAF, THF, 1.5 h, 64% overall; (c) Bu₃SnH, Et₃B, benzene, 24 h, 43% of 48 and 18% of 49; (d) RhCl₃.3H₂O, EtOH-benzene, 65 °C, 18 h, 84%; (e) LiOH, THF-water, 8 h, *ca* 100%.

The ¹H NMR spectrum, which was complemented by decoupling experiments, showed two sets of olefinic signals at δ 5.76 and δ 5.88, and these signals were coupled (J = 10.2 Hz) to each other with a coupling constant in the expected range for cis geometry at C-4a and C-9b. The aromatic proton at C-7 was still present [at δ 6.86 (s)]. The hydrogen at C-4a (adjacent to the oxygen of the furan ring) resonated at δ 5.08--5.18 (m) and was coupled (J = 8.0 Hz) with the adjacent C-9b bis-allylic methine proton (δ 3.98), as shown by irradiation of either signal.

Finally, the signal characteristic of the methine hydrogen at C-3 resonated at δ 2.89 (m) and, as expected, irradiation of the latter caused the signal (δ 5.88) corresponding to the C-2 olefinic hydrogen to collapse to a dd (J = 10.0, 3.2 Hz). It will be noted that, although the junction of the dihydrofuran ring (C-4a and C-9b) can be assigned with confidence as being *cis*, the stereochemistry of the CH₂CO₂Et substituent is tentatively assigned on the assumption that the stereochemistry for the precursor 46 results from the expected inversion in the Mitsunobu coupling.

The formation of 49 presumably arises by intramolecular abstraction of H_a in 47, by the benzene radical resulting from homolytic cleavage of the carbon-bromine bond (Scheme 7), to form an intermediate radical which then collapses to give the observed product.

It will be noted that the radical closure-ring opening reaction was conducted under high dilution (0.01 M in substrate; 0.02 M in stannane) to compensate for the fact that the stannane is added in one portion. Under these conditions, no product coming from simple reduction of the bromide was observed and the chlorine atom present on the benzene ring survived.

Isomerization of 48 with rhodium chloride monohydrate under carefully defined conditions⁶⁶ gave 51 in excellent yield (84%). Both 48 and 51 were hydrolysed to the corresponding carboxylic acids 50 and 52, respectively, and these were then evaluated for inhibition of leukotriene biosynthesis. Unfortunately, only marginal activity was found.#

[#] We thank Merck Frosst Canada for the bioassay, which was done by the method of reference 58. Compound 52: 13% inhibition of leukotriene biosynthesis at 1 μ g/mL; compound 50: 17% inhibition at 1 μ g/mL.

2) Conclusion

We have demonstrated that radical ring opening of cyclopropanes can be used by itself and that the method can be combined with the well documented radical cyclization to provide a radical closure-ring opening sequence.

An extension of this work could be a process whereby a series of radical closure and ring openings, which do not necessarily involve the formation of benzofurans, would be combined together to afford a reaction commonly called a 'zip' reaction. This would lead to interesting polycyclic compounds. We have not yet had the opportunity to investigate such processes.

III. EXPERIMENTAL

Unless otherwise stated the following particulars apply. Reactions involving water-sensitive reagents were carried out under argon, purified by passage through a column (3.5 x 42 cm) of R-311 catalyst# and then through a similar column of Drierite.

Glassware was dried in a oven for at least 3 h (140 °C), cooled in a desiccator, quickly assembled, and sealed with rubber septa (when applicable). Inlet and exit needles for argon were passed through a septum on the apparatus, and argon was purged through the system. The exit needle was then removed, and the apparatus was kept under a static pressure of argon. Stirring was effected by using a dry Teflon-coated magnetic stirring bar. Isolated compounds were homogeneous as judged by ¹H NMR measurements. When a solution was injected over a specified time, the time refers to the main volume of the solution and not to the solvent used as a rinse; the latter was usually injected at a fast dropwise rate.

Solvents were distilled before use for chromatography or extractions. Where required, solvents and reagents were dried with suitable drying agents and distilled under argon, except for hexane and methanol, which were protected from moisture using a calcium sulfate drying tube.

Products were isolated from solution by concentration under water pump vacuum at 30 °C using a rotary evaporator. Where compounds were

[#]Supplied by chemicals Dynamics Corp., South Plainfield, N. J.

isolated by simple evaporation of their solutions, the residues were kept under vacuum (<0.1mm) until of constant weight. Melting points were measured with a Kofler block melting point apparatus. Boiling points reported for products distilled in a Kugelrohr apparatus refer to the oven temperature. Commercial silica (Merck 60F-254) thin layer chromatography (TLC) plates were used. Silica gel for flash column chromatography was Merck type 60 (230-400 mesh). Products isolated after flash chromatography were homogeneous (TLC, and/or ¹H NMR). Alumina for column chromatography was neutral and of grade III. TLC plates were examined under UV radiation (254 nm), treated with iodine vapor, and/or charred on a hot plate after being sprayed with a solution of phosphomolybdic acid.# or anisaldehyde.##

All vapor phase chromatographic (VPC) analyses were performed on a Hewlett-Packard 5830A gas chromatograph equipped with an FID detector using prepacked Hewlett-Packard 6ft x 1/8 in o.d. stainless steel analytical columns with nitrogen as the carrier gas: The specification of the column used for vapor phase chromatographic analysis was 10% OV-1, 80/100 Chromosorb W-HP. A Branson ultrasonic bath (Model B-12) was used as a source of ultrasound.

Anisaldehyde (15 drops) in a mixture of 95% ethanol (94 mL) and concentrated sulfuric acid (6 mL).

^{##} Phosphomolybdic acid (15 g) and ceric ammonium sulfate (2.5 g) dissolved in a mixture of water (485 mL) and concentrated sulfuric acid.

Elemental combustion analyses were performed in the microanalytical laboratories of the University of Alberta. An X-ray crystal structure was determined by Dr. B. Santarciero at the University of Alberta. Infrared spectra were recorded with a Perkin-Elmer 297 spectrophotometer or a Nicolet 7000 FT-IR model. Liquids and solids were run as solutions in the specified solvent in 0.5-mm potassium bromide cells. Proton NMR spectra were recorded with a Bruker WP-80 (at 80 MHz), WP-200 (at 200 MHz), Bruker AM-300 (at 300 MHz), or Bruker AM-400 (at 400 MHz) spectrometer in the specified deuterated solvent with tetramethylsilane (TMS) as an internal standard. 13C NMR spectra were recorded with a Bruker AM-300 (at 75.5 MHz) or Bruker AM-400 (at 100.6 MHz) spectrometer in the specified deuterated solvent with tetramethylsilane (TMS) as an internal standard. Where indicated, the assignment of resonances to carbon type was determined using the APT^{69,70} sequence. The following abbreviations are used in the text: s, singlet; d, doublet; t, triplet; q, quartet; m, multiplet; J, coupling constant; δ, chemical shift. Mass spectra were recorded on an AEI MS-12 or MS-50 mass spectrometer at an ionizing voltage of 70 eV.

Materials. Dry 1,2-dimethoxyethane (DME), dioxane, tetrahydrofuran, ether, and benzene were distilled from sodium-benzophenone ketyl; dry carbon tetrachloride, chloroform, dichloromethane, hexane, pyridine, toluene, and triethylamine were distilled from calcium hydride. Dry DMSO and dimethylaniline were distilled from calcium hydride under reduced pressure (15 mm). Dry diglyme was distilled from calcium hydride and then from lithium aluminum hydride under reduced pressure (40 mm). Dry dimethylformamide (DMF) was distilled from molecular sieves 4Å under

reduced pressure (40 mm). Dry methanol was distilled shortly before use from magnesium. Anhydrous ethanol was commercial dehydrated ethanol from U.S. Industrial Chemicals Co. Azobis(iso-butyronitrile) (AIBN) from Eastman was used without further purification and stored at 5°C.

General procedure for photochemical radical ring-opening. The substrate was placed in a 10- or 25-mL oven-dried Pyrex flask with an optically flat panel in its upper side and containing a Teflon-coated stirring bar. The system was flushed with argon, and dry solvent was injected. The flask was lowered into a cold-bath (-70 °C to 0 °C, depending on the experiment) and irradiated from above with a 275 W General Electric Sunlamp. Triphenyltin hydride (or tributyltin hydride) (1.5 equiv) was injected over a period of 1 min and stirring was continued for 0.5 to 4 h at the specified temperature. The mixture was transferred to a round-bottomed flask and evaporated, and the residue was then processed as described for the individual examples.

General procedure for thermal radical ring-opening. The substrate was placed in a 10- or 25-mL oven-dried round-bottomed flask containing a Teflon-coated stirring bar and equipped with a reflux condenser sealed by a rubber septum. The system was flushed with argon for 5-10 min, and dry benzene was injected. Triphenyltin hydride (or tributyltin hydride) (1.5 equiv) was injected over 1 min and AIBN (0.1 equiv) was added in one portion. The flask was lowered into an oil bath preheated to 100 °C, and the mixture was refluxed for 0.25 to 3 h, after which it was cooled and evaporated. The residue was then processed as described for the individual examples.

Ethyl $(1\alpha,6\alpha,7\alpha)$ -2-Oxobicyclo[4.1.0]heptane-7-carboxylate (11b).

Ethyl (dimethylsulfuranylidene)acetate⁴¹ (2.94 g, 19.9 mmol) was injected over 4 h into a refluxing solution of 2-cyclohexen-1-one (957 mg, 9.95 mmol) in dry benzene (9 mL). Refluxing was continued for an additional 14 h, and the solvent was then evaporated. Flash chromatography of the residue over silica gel (6.5 cm x 20 cm) using first 10% ethyl acetate--hexane and then gradually increasing proportions of ethyl acetate (up to 40%) afforded slightly impure (TLC, silica, 25% ethyl acetate--hexane) 11b (1.44 g). Distillation (Kugelrohr; 100 °C, 0.08 mm) gave pure (TLC, 25% ethyl acetate--hexane) 11b (1.32 g, 73%) as a white solid: FT-IR (CHCl₃ cast) 2940, 1725, 1700, 1295, 1180 cm⁻¹; ¹H NMR (CDCl₃, 300 MHz) δ 1.29 (t, J = 7.0 Hz, 3 H), 1.65 (m, 1 H), 1.81 (m, 1 H), 1.92--2.26 (m, 4 H), 2.24--2.38 (m, 3 H), 4.17 (q, J = 7.0 Hz, 2 H); ¹³C NMR (CDCl₃, 75.5 MHz) δ 14.07, 18.06, 20.34, 23.55, 24.66, 33.49, 36.91, 61.07, 171.09, 205.07; exact mass, m/z calcd for C₁₀H₁₄O₃ 182.0943, found 182.0942. Anal. Calcd for C₁₀H₁₄O₃: C, 65.91; H, 7.74. Found: C, 65.49; H, 7.59.

Ethyl (1α , 2β , 6α , 7α)- and (1α , 2α , 6α , 7α)-2-Hydroxybicyclo[4.1.0]heptane-7-carboxylate (11c).

Sodium borohydride (109 mg, 2.87 mmol) was added over 3 min to a cold (0 °C) and stirred suspension of 11b (476 mg, 2.61 mmol) and cerium trichloride heptahydrate (1.09 g, 2.92 mmol) in methanol (7 mL). Stirring was continued for 30 min. The mixture was quenched by addition of water (10 mL), and extracted with ether (2 x 25 mL). The combined organic extracts were washed with brine (1 x 15 mL) and dried (MgSO₄). Evaporation of the solvent and flash chromatography of the residue over silica gel (2 x 20 cm) using 40% ethyl acetate--hexane gave alcohols 11c (410 mg, 85%) as a colorless oil: FT-IR (CHCl₃ cast) 3430, 2940, 1720, 1700, 1300, 1175, 1050 cm⁻¹; ¹H NMR (CDCl₃, 300 MHz) δ 1.07 (m, 1 H), 1.10--1.20 [m, including a triplet at 1.27 (J = 7.3 Hz), 11 H], 2.23 (broad m, 0.41 H), 2.60 (broad s, 0.61 H), 4.04 (broad s, 0.8 H), 4.12 (two superimposed quartets, J = 7.3 Hz, 2 H), 4.21 (m, 0.2 H); ¹³C NMR (CDCl₃, 75.5 MHz) (major isomer) δ 14.22, 15.84, 21.97, 22.01, 24.21, 29.01, 30.21, 60.47, 65.80, 174.00; (minor isomer) δ .20.09, 21.89, 22.70, 23.99, 28.92, 29.75, 65.63, 174.11; exact mass, m/z calcd for $C_{10}H_{15}O_2$ 167.1052, found 167.1072. Anal. Calcd for C₁₀H₁₅O₂: C, 65.19; H, 8.76. Found: C, 65.38; H, 8.67.

Ethyl $(1\alpha,2\alpha,6\alpha,7\alpha)$ - and $(1\alpha,2\beta,6\alpha,7\alpha)$ -2-(Phenylseleno)bicyclo-[4.1.0]heptane-7-carboxylate (11d).

Phenylselenocyanate (982 mg, 5.4 mmol) and then tributylphosphine (1.34 mL, 5.4 mmol) were added, each in one portion, to a cold (0 °C) and stirred solution of 11c (332 mg, 1.8 mmol) in dry THF (7 mL). Stirring was

continued for 4 h at 0 °C. Evaporation of the solvent and flash chromatography of the residue over silica gel (3 x 20 cm) using successively hexane, 50% dichloromethane--hexane, and 5% ethyl acetate--hexane gave 11d (468 mg, 80%) as a slightly yellow oil: FT-IR (CHCl₃ cast) 2935, 1720, 1575, 1300, 1182, 740, 685 cm⁻¹; ¹H NMR (CDCl₃, 300 MHz) δ 1.15 [m, including two superimposed triplets at 1.25 (J = 7.2 Hz), 5 H], 3.62 (m, 0.2 H), 3.79 (m, 0.8 H), 4.10 (two superimposed quartets, J = 7.2 Hz, 2 H), 7.25 (m, 3 H), 7.58 (m, 2 H); ¹³C NMR (CDCl₃, 75.5 MHz) (major isomer only) δ 14.20, 21.88, 22.17, 24.89, 25.56, 27.60, 28.39, 39.22, 60.28, 127.50, 128.78, 135.15, 173.65; exact mass, m/z calcd for C₁₆H₂₀O₂Se 324.0629, found 324.0629. Anal. Calcd for C₁₆H₂₀O₂Se: C, 59.44; H, 6.24; O, 9.90. Found: C, 59.74; H, 6.28.

Ethyl (2-Cyclohexen-1-yl)acetate (11e).

The general procedure for thermal radical ring opening was followed using 11d (179 mg, 0.55 mmol) in dry benzene (5.5 mL), triphenyltin hydride (183 μ L, 0.72 mmol), and AIBN (4 mg, 0.03 mmol). Refluxing was continued for 1 h and the mixture was then evaporated. Kugelrohr distillation (90 °C, 1.5 mm) of the residue afforded 11e (85.4 mg, 92%) as a colorless oil: FT-IR (CHCl₃ cast) 2920, 1740, 1160 cm⁻¹; ¹H NMR (CDCl₃, 200 MHz) δ 1.19--1.38 [m, including a triplet at 1.27 (J = 7.2 Hz), 4 H], 1.45--1.92 (m, 4 H), 2.0 (m, 2 H), 2.28 (m, 2 H), 2.60 (m, 2 H), 4.15 (q, J = 7.2 Hz, 2 H), 5.55 (ddd, J = 10.1 Hz, 4.1, 2.5 Hz, 1 H), 5.72 (ddd, J = 10.1, 5.6, 3.8 Hz, 1 H); ¹³C NMR (CDCl₃, 75.5 MHz) δ 14.30, 21.01, 25.05, 28.83, 32.31, 40.90, 60.23, 128.11, 130.19, 172.84; exact mass, m/z

calcd for $C_{10}H_{16}O_2$ 168.1151, found 168.1151. Anal. Calcd for $C_{10}H_{16}O_2$: C, 71.39; H, 9.59. Found: C, 71.08; H, 9.27.

Ethyl (15 α ,16 α)-Dihydro-3-methoxy-17-oxo-3'H-cycloprop[15,16]estra-1,3,5,(10),15-tetraenyl-3'-carboxylate (12b).#

Ethyl (dimethylsulphuranylidene)acetate⁴¹ (663 mg, 4.48 mmol) was added with stirring over 3 h (syringe pump) to a warm (55 °C) solution of 12a (633 mg, 2.24 mmol) in dry DMSO (7.4 mL). Stirring at 55 °C was continued for 18 h, and water (20 mL) was added. The mixture was extracted with dichloromethane (50 mL) and the organic extract was washed with 1:1 brinewater (1 x 50 mL), and dried (MgSO₄). Evaporation of the solvent and flash chromatography of the residue over silica gel (3.0 x 20 cm) using 20% ethyl acetate--hexane afforded impure 12b (546 mg). The material, which was used directly in the next step, had: 1 H NMR (CDCl₃, 200 MHz) (major and most characteristic signals only) δ 0.98 (s, about 2.1 H), 1.04 (s, 0.65 H), 1.28 (t, J = 7.6 Hz), 3.76 (s, 3 H), 4.15 (dq, J = 7.6, 2.4 Hz, 2 H), 6.65 (d, J = 2.8 Hz, 1 H), 6.71 (d, J = 8.0, 2.8 Hz, 1 H). 7.16 (d, J = 8.0 Hz, 1 H).

[#] Stereochemistry shown at C(3') is an arbitrary assignment; that at C(15) and C(16) is made by analogy to the transformation $18a \rightarrow 18b$

Ethyl (15 α ,16 α)-Dihydro-17-hydroxy-3-methoxy-3'*H*-cycloprop[15,16]-estra-1,3,5,(10),15-tetraenyl-3'-carboxylate (12c).#

Sodium borohydride (66 mg, 1.75 mmol) was added over 3 min to a stirred suspension of crude 12b (536 mg, 1.45 mmol) and cerium trichloride heptahydrate (652 mg, 1.75 mmol) in methanol (7 mL). Stirring was continued at room temperature for 2 h. Further portions of cerium trichloride heptahydrate (325 mg, 0.88 mmol) and of sodium borohydride (33 mg, 0.88 mmol) were then added and stirring was continued for 1 h. The mixture was quenched by addition of water (1 x 10 mL) and extracted with ethyl acetate (2 x 20 mL). The combined extracts were washed with water (1 x 10 mL), dried (MgSO₄), and evaporated. Flash chromatography of the residue over silica gel (3 x 20 cm) using first 20% ethyl acetate--hexane and then 25% ethyl acetate--hexane gave crude 12c (471 mg), which was used directly in the next step. The material had: 1H NMR (CDCl₃, 200 MHz) δ 0.83 (s, 0.37 H), 0.86 (s, 1.56 H), 0.88 (s, 0.55 H), 1.04 (s, 0.25 H), 1.27 (t, J = 7.3 Hz, 3.7 H), 1.32--1.70 (m, 4.5), 1.71--2.04 (m, 4.1), 2.05--2.40 (m, 4 H), 2.73--3.0 (m, 2.2 H), 3.78 (s, 3.06 H), 4.12 (m, 2.5 H), 6.65 (d, J = 2.9) and 6.71 (dd, J = 8.4, 2.9 Hz) [both signals together correspond to 2.0 H], 7.12--7.25 [m, including doublet at 7.17 (J = 8.4 Hz), 1.06 H].

#Stereochemistry shown at C(3') is an arbitrary assignment; that at C(15), C(16) and C(17) is made by analogy to the transformation $18a \rightarrow 18b \rightarrow 18c$.

Ethyl (15 α ,16 α)-Dihydro-3-methoxy-17-(phenylseleno)-3'H-cycloprop-[15,16]estra-1,3,5,(10),15-tetraenyl-3'-carboxylate (12d).

Phenylselenocyanate (263 mg, 1.45 mmol) in dry THF (1 mL) was added with stirring over 2 h (syringe pump) to a warm (45 °C) solution of crude 12c (268 mg, 0.723 mmol) and tributylphosphine (361 µL, 1.45 mmol) in dry THF (4 mL). Stirring was continued at 45 °C for 16 h and the solvent was evaporated. Flash chromatography of the residue over silica gel (2.0 x 20.0 cm) using first 30% dichloromethane--hexane (to remove diphenyl diselenide) followed by 15% ethyl acetate--hexane afforded a mixture of selenides 12d in a ratio of 95:5 [1H NMR (300 MHz)] (218 mg, 59% based on unsaturated estrone 12a) as a gummy white solid: FT-IR (CHCl3 cast) 2932, 1722, 1500, 1282, 1172, 1037, 738 cm⁻¹; ¹H NMR (CDCl₃, 200 MHz) δ 0.91 (s, 0.3 H), 1.0 (s, 2.7 H), 1.21 (t, J = 7.3 Hz, 3 H), 1.36-1.68 (m, 4 H), 1.74-2.46 (m, 8 H), 2.82--3.0 (m, 2 H), 3.74 (s, 3 H), 3.80 (s, 1 H), 4.06 (q, J = 7.3 Hz, 2 H), 6.63 (d, 2.9 Hz, 1 H), 6.70 (dd, J = 8.5, 2.9 Hz, 1 H), 7.14 (d, J = 8.5 Hz, 1 H), 7.20--7.32 (m, 3 H), 7.50--7.69 (m, 2 H); 13 C NMR (CDCl₃, 75.5 MHz) (major peaks only) δ 14.22, 24.36, 26.46, 26.75, 28.09, 28.40, 29.57, 31.34, 37.06, 41.07, 42.04, 44.08, 52.83, 55.19, 56.78, 60.51, 111.45, 113.87, 125.90, 127.20, 129.13, 130.23, 132.30, 133.83, 137.72, 157.60, 172.72; exact mass, m/z calcd for $C_{29}H_{34}O_{3}Se$ 510.1674, found 510.1672. Anal. Calcd for C₂₉H₃₄O₃Se: C, 68.36; H, 6.73; O, 9.43. Found: C, 68.17; H, 6.82; O. 9.37.

Ethyl (3-Methoxyestra-1,3,5(10),16-tetraen-15 β -yl)acetate (12e).#

With one modification, the general procedure for thermal radical ring opening was followed using selenides 12d (129 mg, 0.252 mmol) in benzene (2.5 mL), tributyltin hydride (88 μ L, 0.33 mmol), and AIBN (3 mg, 0.02 mmol). In this particular experiment, further portions of tributyltin hydride (88 µL, 0.33 mmol) and AIBN (3 mg, 0.02 mmol) were added after 4 h, since the reaction had stopped (TLC control, silica, 10% ethyl acetate--hexane). Stirring under reflux was continued for 12 h more. The mixture was cooled and evaporated. Flash chromatography of the residue over silica gel (1.5 x 20.0 cm) using 10% ethyl acetate--hexane afforded pure 12e (80 mg, 90%) as a white solid: FT-IR (CHCl₃ cast) 3248, 1733, 1500, 1255; ¹H NMR (CDCl₃, 300 MHz) δ 0.97 (s, 3 H), 1.28 (t, J = 7.2 Hz, 3 H), 1.43-1.70 (m, 4 H), 1.71-1.88 (m, 2 H), 1.95-1.882.09 (m, 1 H), 2.20--2.41 (m, 3 H), 2.56 (dd, J = 15.6, 3.6 Hz, 1 H), 2.80--2.98 (m, 2 H), 2.98-3.08 (m, 1 H), 3.78 (s, 3 H), 4.15 (q, J = 7.2 Hz, 2 H), 5.89 (dd, J = 6.0, 3.0Hz, 1 H), 5.97 (d, J = 6.0 Hz, 1 H), 6.66 (d, J = 2.9 Hz, 1 H), 6.72 (dd, J = 8.8, 2.9 Hz, 1 H), 7.18 (J = 8.8 Hz, 1 H); 13 C NMR (CDCl₃, 75.5 MHz) δ 14.30, 22.26, 26.02, **27.61**, 29.58, 35.20, 35.42, 37.58, 40.83, 45.12, 46.39, 55.21, 55.79, 60.35, 111.34, 113.84, 125.70, 132,95, 133.12, 137.62, 143.67, 157.58, 173.32; exact mass, m/z calcd for C₂₃H₃₀O₃ 354.2195, found 354.2193. Anal. Calcd for C₂₃H₃₀O₃: C, 77.93; H, 8.53. Found: C, 77.96; H, 8.25.

[#]Stereochemistry at C(15) follows from the sense of cyclopropanation

2-(Cyclohexen-1-yl)diazoacetate (13b).

The procedure is based on a general literature method. 35 Dry N,Ndimethylaniline (1.55 mL, 12.24 mmol) was added to a cold (0 °C) and stirred 10.2 mmol) and [(psolution of 2-cyclohexen-1-ol (1.0 g, toluenesulfonyl)hydrazono]acetyl chloride⁶⁹ (3.31 g, 12.75 mmol) in dry dichloromethane (68 mL). After 20 min at 0 °C, dry triethylamine (7.1 mL, 51 mmol) was injected over about 1 min and stirring was continued for 15 min. The cold-bath was removed, and after a further 30 min, the mixture was quenched with water (30 mL), and concentrated. The residue was extracted with 10% ethyl acetate--hexane (2 x 65 mL) and the combined extracts were washed with saturated aqueous citric acid (2 x 30 mL). The combined aqueous layers were extracted with 10% ethyl acetate--hexane (1 x 30 mL), and the organic extract was washed with saturated aqueous citric acid (1 x 5 mL). All the organic extracts were combined, dried (MgSO₄), and evaporated. Flash chromatography of the residue over silica gel (4 x 20 cm) using 8% ethyl acetate--hexane afforded 13b (1.19 g, 70%) as a bright yellow oil, containing trace impurities. The material was distilled (Kugelrohr, 45 °C, 0.05 mm) for characterization: FT-IR (CHCl₃ cast) 3120, 2950, 2055, 1690, 1380, 1180; ¹H NMR (CDCl₃, 300 MHz) δ 1.55--1.81 (m, 3 H), 1.81--2.18 (m, 3 H), 4.74 (broad s, 1 H), 5.35 (m, 1 H), 5.72 (ddt, J = 10.0, 3.8, 2.1 Hz, 1 H), 5.96 (ddt, J = 10.0, 3.8, 1.2 Hz, 1 H); ¹³C NMR (CDCl₃, 75.5 MHz) δ 18.60, 24.86, 28.49, 68.61, 125.68, 132.67; exact

mass, m/z calcd for C₈H₁₀N₂O₂ 166.0742, found 166.0725. Anal. Calcd for C₈H₁₀N₂O₂: C, 57.82; H, 6.06; N, 16.86. Found: C, 57.81; H, 5.98; N, 16.81.

 $(2a\alpha,2b\alpha,5a\alpha,5b\alpha)$ -Hexahydrocyclopropa[cd]benzofuran-2(2aH)-one (13c).

A solution of 13b (1.65 g, σ — mol) in dry toluene (40 mL) was injected over 12 h into a refluxing solution of bis-(N-tert-butyl salicylaldiminato)copper(II)⁷⁰ (136 mg, 0.328 mmol) in dry toluene (210 mL) contained in a 500-mL round bottomed flask equipped with a condenser and heated by an oil bath set at 135 °C. After the addition was complete the mixture was cooled and evaporated. Flash chromatography of the residue over silica gel (3 x 18 cm) using 40% ethyl acetate--hexane afforded 13c (798 mg, 88%) as a slightly yellow oil: FT-IR (CHCl₃ cast) 2950, 1760, 1340, 970 cm⁻¹; ¹H NMR (CDCl₃, 300 MHz) δ 1.40--1.78 (m, 5 H), 1.85 (m, 1 H), 2.08 (m, 2 H), 2.36 (dt, J = 8.0, 6.2 Hz, 1 H), 4.92 (dt, J = 6.0, 2.6 Hz, 1 H); ¹³C NMR (CDCl₃, 75.5 MHz) δ 14.61, 18.07, 18.52, 22.60, 24.07, 24.70, 74.03, 175.69; exact mass, m/z calcd for C₈H₁₀O₂ 130.0681, found 130.0682. Anal. Calcd for C₈H₁₀O₂: 69.54; H, 7.29. Found: C, 69.18; H, 7.31.

 $(1\alpha,2\beta,6\alpha,7\beta)$ -2-Hydroxy-N,N-dimethylbicyclo[4.1.0]heptane-7-carboxamide (13d).

The procedure is based on a general literature method.³⁶ Cold (-70 °C) dimethylamine (30 µL, 0.456 mmol) and then trimethylaluminum (2 M in toluene, 0.217 mL, 0.434 mmol) were added to dry dichloromethane (1 mL) contained in a 10-mL round-bottomed flask equipped with a condenser. The mixture was stirred for 30 min at room temperature and lactone 13c in dry dichloromethane (0.2 mL, plus 0.2 mL as a rinse) was injected over about 5 min. Stirring was continued for 3 h at room temperature and then at reflux for 5 h. The mixture was cooled in ice and quenched by careful addition of aqueous hydrochloric acid (1 M, 0.5 mL). The aqueous layer was extracted with dichloromethane (2 x 7 mL) and the combined organic extracts were dried (MgSO₄) and evaporated. Kugelrohr distillation (90 °C, 0.05 mm) afforded 13d (37 mg, 93%) as a white solid: FT-IR (CHCl₃ cast) 3287, 2943, 2870, 1615, 1451, 1048, 711 cm⁻¹; 1 H NMR (CDCl₃, 300 MHz) δ 0.82 (m, 1 H), 0.97 (m, 1 H), 1.13 (ddq, J = 13.0, 4.5, 2.2 Hz, 1 H), 1.43 (dm, J = 13.0 Hz, 1 H), 1.77 (m, 2 H),1.94 (m, 2 H), 3.03 (s, 3 H), 3.17 (s, 3 H), 4.12 (tt, J = 11.0, 7.0 Hz, 1 H), 5.30 (d, J = 1.94 (m, 2 H), 3.03 (s, 3 H), 3.17 (s, 3 H), 4.12 (tt, J = 11.0, 7.0 Hz, 1 H), 5.30 (d, J = 1.94 (m, 2 H), 3.03 (s, 3 H), 3.17 (s, 3 H), 4.12 (tt, J = 11.0, 7.0 Hz, 1 H), 5.30 (d, J = 1.94 (m, 2 H), 3.03 (s, 3 H), 3.17 (s, 3 H), 4.12 (tt, J = 11.0, 7.0 Hz, 1 H), 5.30 (d, J = 1.94 (m, 2 H), 3.03 (s, 3 H), 3.17 (s, 3 H), 4.12 (tt, J = 11.0, 7.0 Hz, 1 H), 5.30 (d, J = 1.94 (m, 2 H), 3.17 (s, 3 H), 4.12 (tt, J = 11.0, 7.0 Hz, 1 H), 5.30 (d, J = 1.94 (m, 2 H), 3.17 (s, 3 H), 4.12 (tt, J = 11.0, 7.0 Hz, 1 H), 5.30 (d, J = 1.94 (m, 2 H), 3.17 (s, 3 H), 4.12 (tt, J = 11.0, 7.0 Hz, 1 H), 5.30 (d, J = 1.94 (m, 2 H), 3.17 (s, 3 H), 4.12 (tt, J = 11.0, 7.0 Hz, 1 H), 5.30 (d, J = 1.94 (m, 2 H), 3.17 (s, 3 H), 4.12 (tt, J = 11.0, 7.0 Hz, 1 H), 5.30 (d, J = 1.94 (m, 2 H), 3.17 (s, 3 H), 4.12 (tt, J = 11.0, 7.0 Hz, 1 H), 5.30 (d, J = 1.94 (m, 2 H), 3.17 (m, 2 H11.5 Hz, 1 H); 13 C NMR (CDCl₃, 75.5 MHz) δ 18.79, 20.00, 20.21, 22.53, 25.84, 31.71, 35.41, 37.57, 66.65, 171.16; exact mass, m/z calcd for $C_{10}H_{17}NO_2$ 183.1259, found 183.1256. In a similar experiment done on a bigger scale [13c (150 mg)], 13d (180 mg, 90%) was obtained.

 $(1\alpha,2\alpha,6\alpha,7\beta)$ -N,N-Dimethyl-2-(phenylseleno)bicyclo[4.1.0]heptane-7-carboxamide (13e).

Phenylselenocyanate (236 μ L, 1.75 mmol) in dry THF (0.5 mL) was added over 15 min (syringe pump) to a refluxing solution of 13d (168 mg, 0.874 mmol) and tributylphosphine (436 μ L, 1.75 mmol) in dry THF (3.9 mL) contained in a 10-mL round-bottomed flask equipped with a condenser. Stirring was continued for 14 h and the mixture was cooled and evaporated. Flash chromatography of the residue over silica gel (2 x 20 cm) using 40% ethyl acetate--hexane gave 13e (232 mg, 78%) as an orange oil. The material contained slight impurities [¹H NMR (200 MHz)] but was suitable for the next stage: FT-IR (CHCl₃ cast) 2930, 2855, 1841, 1580, 1140, 740, 685 cm⁻¹; ¹H NMR (CDCl₃, 300 MHz) δ 1.2 (m, 1 H), 1.34--1.63 (m, 5 H), 1.75 (m, 2 H), 1.88 (m, 1 H), 2.93 (s, 3 H), 3.04 (s, 3 H), 4.0 (ddd, J = 8.1, 5.1, 2.3 Hz, 1 H), 7.25 (m, 3 H), 7.61 (m, 2 H); ¹³C NMR (CDCl₃, 75.5 MHz) δ 15.18, 19.57, 20.34, 21.50, 22.85, 28.97, 34.89, 36.17, 37.02, 127.08, 128.98, 130.37, 133.97, 170.24; exact mass, m/z calcd for C₁₆H₂₁NOSe 323.0789, found 323.0791. Anal. Calcd for C₁₆H₂₁NOSe: C, 59.62; H, 6.57; N, 4.34. Found: C, 59.45; H, 6.51; N, 4.45.

N,N-Dimethyl-2-cyclohexene-1-acetamide (13f).

With one exception, the general procedure for thermal radical ring opening was followed using selenide 13e (221 mg, 0.685 mmol) in benzene (6.8 mL), triphenyltin hydride (262 μ L, 1.02 mmol), and AIBN (11 mg, 0.07 mmol). In this particular experiment a second portion of AIBN (11 mg, 0.07 mmol) was added after 30 min at reflux temperature. Refluxing was continued for 2 h after the second addition of initiator, and the mixture was then cooled and evaporated. Kugelrohr distillation of the residue (90 °C, 0.4 mm) afforded 13f (109 mg, 96%) as a colorless oil: FT-IR (CHCl₃ cast) 3020, 2924, 1647, 1395, 1140 cm⁻¹; ¹H NMR (CDCl₃, 300 MHz) δ 1.28 (m, 1 H), 1.51-1.78 (m, 2 H), 1.85 (m, 1 H), 1.97 (m, 2 H), 2.3 (m, 2 H), 2.69 (m, 1 H), 2.96 (s, 3 H), 3.03 (s, 3 H), 5.59 (dm, J = 10.0 Hz, 1 H), 5.72 (ddd, J = 10.0, 5.9, 3.7 Hz, 1 H); ¹³C NMR (CDCl₃, 75.5 MHz) δ 21.12, 25.18, 29.14, 32.25, 35.42, 37.46, 39.41, 127.70, 131.07, 172.10; exact mass, m/z calcd for C₁₀H₁₇NO 167.1310, found 167.1308.

$(1\alpha,2\beta,6\alpha)$ -7,7-Dichloro-4,4,6-trimethylbicyclo[4.1.0]heptan-2-ol (14b).

Benzyltriethyl-ammonium chloride (35 mg) was added to a cold (0 °C) and stirred solution of 3,5,5-trimethyl-2-cyclohexen-1-ol (1.0 g, 7.13 mmol) in

chloroform (15 mL). Aqueous sodium hydroxide 50% w/w (7.1 mL) was then added over a period of 5 min.34 The course of the reaction was closely monitored by TLC (silica, 20% ethyl acetate hexane),# and, after 40 min at 0 °C, the reaction was stopped by addition of water (15 mL), and ether (25 mL) was added. The aqueous layer was extracted with ether (2 X 25 mL) and the combined organic layers were dried (MgSO₄₎. Evaporation of the solvent and flash chromatography of the residue over silica gel (3.0 cm X 20.0 cm) using 15% ethyl acetate--hexane gave 14b (1.14 g, 71%) as a white solid: FT-IR (CHCl₃ cast) 3220, 2956, 1050, 843 cm⁻¹; ¹H NMR (CDCl₃, 300 MHz) δ 0.87 (s, 3 H), 0.95 (s, 3 H), 1.24 (dd, J = 12.3, 11.8 Hz, 1 H), 1.41 (s) and 1.44 (dd, J = 14.5, 2.1 Hz) [both signals together correspond to 4 H], 1.61 (ddd, J = 13.1, 7.5, 2.1 Hz, 1 H), 1.69 (d, J = 7.5 Hz) and 1.75 (dd, J = 14.5, 0.7 Hz) [both signals together correspond to 2 H], 1.97 (broad s, 1 H), 4.32 (dt, J = 11.2, 7.5 Hz, 1 H); ¹³C NMR (CDCl₃, 75.5 MHz) δ 25.21, 25.99, 30.95, 32.04, 32.56, 36.66, 39.79, 42.04, 65.75 71.25; exact mass, m/z calcd for $C_{10}H_{16}Cl_2O$ 222.0578, found 222.0576. Anal. Calcd for C₁₀H₁₆Cl₂O: C, 53.82; H, 7.23; Cl, 31.78. Found: C, 53.68; H, 7.30; Cl, 32.01.

 $(1\alpha,5\alpha,6\alpha)$ -7,7-Dichloro-1,3,3-trimethyl-5-(phenylseleno)bicyclo[4.1.0]-heptane (14c).

[#] The desired product is slowly transformed into a less polar (TLC) compound. It is best to stop the reaction a little short of completion.

Method (a). Phenylselenocyanate (342 mg, 1.88 mmol) in dry THF (1 mL) was added by syringe pump over 1 h to a refluxing solution of dichlorocyclopropane alcohol 14b (210 mg, 0.94 mmol) and tributylphosphine (0.47 mL, 1.88 mmol) in dry THF (2 mL). After 16 h the mixture was cooled to room temperature and evaporated. Flash chromatography of the residue ever silica gel (2 x 20 cm) using 10% ethyl acetate--hexane gave 14c (539 mg) contaminated with diphenyl diselenide. This material was dissolved in dry THF-ethanol (4:1) (10 mL) and cooled to -20 °C. Sodium borohydride (100 mg) was added and the mixture was stirred at -20 °C for 10 min. Bromoacetic acid (400 mg) was then added, the cold-bath was removed, and stirring was continued for 30 min. The mixture was then diluted with ether (15 mL) and quenched with saturated aqueous sodium bicarbonate (20 mL). The aqueous layer was extracted with ether (1 x 15 mL) and the combined extracts were washed with water (1 x 10 mL) and brine (1 x 10 mL), and dried (MgSO₄). Evaporation of the solvent and flash chromatography of the residue over silica gel (2 x 20 cm) using 3% ethyl acetate--hexane gave selenide 14c (282 mg, 82%) as a very slightly yellow solid: FT-IR (CHCl₃ cast) 2953, 1580, 1478, 1437, 734, 691 cm⁻¹; ¹H NMR (CDCl₃, 300 MHz) δ 0.89 (s, 3 H), 1.08 (s, 3 H), 1.43 (s, 3 H), 1.44-1.59 (m, 3 H), 1.63 (dd, J = 15.1, 7.3 Hz, 1 H), 1.70 (d, J = 1.4 Hz, 1 H), 3.66 (dm, J = 7.0 Hz, 1 H), 7.32 (m, 3 H), 7.55 (m, 2 H); ¹³C NMR (CDCl₃, 75.5) MHz) δ 26.88, 28.05, 29.33, 30.21, 32.14, 32.76, 33.16, 33.58, 38.58, 40.34, 40.78, 72.74, 128.11, 130.06, 131.82, 133.10; exact mass, m/z calcd for $C_{16}H_{20}Cl_2Se$ 362.0107, found 362.0064. Anal Calcd for C₁₆H₂₀Cl₂Se: C, 53.05; H, 5.57. Found: C, 52.93; H, 5.59.

Method (b). (i) $(1\alpha,2\beta,6\alpha)$ -7,7-Dichloro-4,4,6-trimethylbicyclo-[4.1.0]heptan-2-yl 4-methylbenzenesulfonate. Freshly recrystallised p-toluenesulfonyl chloride (2.15 g, 11.25 mmol) and then 4-(dimethylamino)-

pyridine (0.10 g, 0.73 mmol) were added in one portion to a solution of 14b (2.03 g, 9.18 mmol) in dry pyridine (9 mL). The mixture was stirred at room temperature for 40 h and then concentrated under reduced pressure. The residue was diluted with ethyl acetate (30 mL) and the solution was washed with 1N aqueous hydrochloric acid (2 x / mL), saturated aqueous sodium bicarbonate (15 mL), water (10 mL), and brine (10 mL), dried (MgSO₄), and evaporated. Flash chromatography of the residue over silica gel (4.0 x 17.0 cm) using 8% ethyl acetate--hexane afforded the required tosylate (2.0 g, 57%) as a white solid: FT-IR (CHCl₃ cast) 2958, 2931, 2870, 1600, 1362, 1188, 924, 556 cm⁻¹; ¹H NMR (CDCl₃, 200 MHz) δ 0.85 (s, 3 H), 0.92 (s, 3 H), 1.38 (s) and 1.44--1.57 (m) [both signals together correspond to 7 H], 1.75 (d, J = 13.4 Hz, 1 H), 2.46 (s, 3 H), 5.22 (ddd, J = 10.8, 8.8, 7.6 Hz, 1 H), 7.38 (d, J = 8 0 Hz, 2 H), 7.88 (d, J = 10.8, 10.88.0 Hz, 2 H); ¹³C NMR (CDC₁₃, 100.6 MHz) δ 22.15, 25.57, 26.32, 31.19, 33.24, 33.39, 34.67, 38.90, 40.07, 70.46, 77.39, 128.16, 130.41, 135.30, 145.09; exact mass, m/z calcd for $C_{17}H_{22}Cl_2O_3$ 376.0633, found 376.0633. Anal. Calcd for C₁₇H₂₂Cl₂O₃: C, 54.11; H, 5.88; Cl, 18.79. Found: C, 54.39; H, 5.82; Cl, 18.53.

The tosylate is rather unstable to silica gel and for larger scale work it is best to crystallise the crude product from cold (0 °C) 1:8 dichloromethane-hexane.solution, and to purify material from the mother liquors by chromatography. In this way overall yields of 80 to 90% were obtained. The compound should not be exposed directly to sunlight. When kept in a refrigerator in the dark, no sign of decomposition was observed after 1 month.

(ii) $(1\alpha,5\alpha,6\alpha)$ -7,7-Dichloro-1,3,3-trimethyl-5-(phenylseleno)bicyclo-[4.1.0]heptane (14c). Sodium hydride (0.128 g, 60% in oil, 3.2 mmol) was washed under argon with THF (3 x 2 mL). The residue was then covered with

dry tetrahydrofuran (5 mL), and diphenyl diselenide (0.50 g, 1.60 mmol) was added. The mixture was refluxed for 60 min, yielding a light yellow suspension of sodium phenylselenide, which was allowed to cool to room temperature. Dry hexamethylphosphoramide (HMPA) (0.6 mL) was injected with stirring and the solid tosylate (1.15 g, 3,05 mmol) was added to the resulting homogeneous solution. The mixture was refluxed for 18 h, cooled to room temperature and poured into diethyl ether (40 mL). The solution was washed with saturated aqueous sodium bicarbonate (2 x 10 mL), saturated aqueous copper sulfate (10 mL), 1:1 brine--water solution (10 mL), and dried (MgSO₄) and evaporated. Flash chromatography of the residue over silica gel (2.0 x 17 cm) with 5% ethyl acetate--hexane afforded 14c (1.0 g, 91%) as a slightly yellow oil, containing about 3 mol% of diphenyl diselenide [by ¹H-NMR (200 MHz)]. The material can be used directly in the next step.

3-(Dichloromethyl)-3,5,5-trimethylcyclohexene (14d).

(a) Photochemical method. The general photochemical method for radical ring opening was followed using triphenyltin hydride (161 μL, 0.63 mmol) and selenide 14c (208 mg, 0.573 mmol) in dry toluene (3.8 mL). The mixture was stirred and irradiated at -23 °C to -10 °C for 1.5 h and then at -10 °C for 1 h. Carbon tetrachloride (0.5 mL) was added and stirring was continued at 25 °C for 1 h (without irradiation). Evaporation of the solvent and flash chromatography of the residue over silica gel (2 x 20 cm) using hexane gave 14d (116 mg), contaminated (TLC, silica, 2% ethyl acetate--hexane) by traces of

impurity. Kugelrohr distillation of a portion (43.9 mg) of this material gave pure [¹H NMR (300 MHz)] 14d (43.2 mg) as a colorless oil. Corrected yield (that would correspond to distillation of the total product): 114 mg (96%): FT-IR (CHCl₃ cast) 2954, 1456, 1365, 1213, 760, 733 cm⁻¹; 1 H NMR (CDCl₃, 300 MHz) δ 0.98 (s,3 H), 1.02 (s, 3 H), 1.28 (s, 3 H), 1.45, (dm, J = 14.2 Hz, 1 H), 1.70 (d, I = 14.2 Hz, 1 H), 1.80 (m, 2 H), 5.53 (dm, J = 10.0 Hz) and 5.55 (s) [both signals together correspond to 2 H], 5.80 (ddd, J = 10.0, 4.9, 3.2 Hz, 1 H); 13 C NMR (CDCl₃, 75.5 MHz) δ 22.55, 28.18, 30.13, 31.76, 38.46, 44.02, 44.62, 83.33, 128.34, 129.54. Anal. Calcd for C₁₀H₁₆Cl₂: C, 57.98; H, 7.79. Found: C, 58.27; H, 7.66.

(b) Thermal method using triethylborane. Triethylborane (1 M in hexane, 5.0 mL, 5.0 mmol) and then triphenyltin hydride (21.93 g, 62.0 mmol) were added dropwise over about 1 min to a cold (-10 °C) and stirred solution of 14c (18.0 g, 50.0 mmol) in dry hexane (500 mL).⁵⁰ After 50 min at -10 °C, carbon tetrachloride (5 mL) was added and the solvents were evaporated. The residue was filtered through a short pad (5 x 7 cm) of silica gel using hexane (500 mL), in order to remove triphenyl(phenylseleno)stannane. The solution was evaporated and Kugelrohr distillation [125-140 °C (27 mm)] of the residue gave 14d (9.50 g, 92%) as a colorless, homogeneous liquid.

 $(1\alpha,2\beta,6\alpha)$ -6-Butyl-7,7-dichloro-4,4-dimethylbicyclo[4.1.0]heptan-2-ol (15b).

Treatment of 3-butyl-5,5-dimethyl-2-cyclohexen-1-ol# (1.3 g, 7.22 mmol) in chloroform (15 mL) with benzyltriethylammonium chloride (36 mg) and aqueous sodium hydroxide 50% w/w (7.1 mL), under identical conditions to those described for 14b, gave 15b (1.39 g, 73%) as a white solid: FT-IR (CHCl₃ cast) 3400, 2955, 1720, 1486, 1053 cm⁻¹; ¹H NMR (CDCl₃, 200 MHz) δ 0.88 (s) and 0.93 (t, J = 7.3 Hz, including a singlet at 0.97) [all signals together correspond to 9 H], 1.13--2.0 (m, 12 H), 4.32 (dt, J = 11.5, 7.5 Hz, 1 H); exact mass, m/z calcd for C₁₃H₂₀Cl₂ [(M - H₂O)+] 246.0942, found 246.0940.

 $(1\alpha,5\alpha,6\alpha)$ -1-Butyl-7,7-dichloro-3,3-dimethyl-5-(phenylseleno)bicyclo-[4.1.0]heptane (15c).

Addition of phenylselenocyanate (1.46 g, 8.06 mmol) in THF (4 mL) to **15b** (1.06 g, 4.03 mmol) and tributylphosphine (2.0 mL, 8.06 mmol) in THF (9 mL), as described for **14b**, gave **15c** (1.50 g, 92%) as a yellowish oil: FT-IR (CHCl₃ cast) 2953, 1598, 1460, 1435, 733, 690 cm⁻¹; ¹H NMR (CDCl₃, 300 MHz) δ 0.92 (t, J = 6.8 Hz, including a singlet at 0.89, 6 H), 1.05 (s, 3 H), 1.22--1.91 (m, 11 H), 3.65 (ddd, J = 7.1, 2.9, 1.4 Hz, 1 H), 7.24--7.30 (m, 3 H), 7.51--7.62 (m, 2 H); ¹³C NMR (CDCl₃, 75.5 MHz) δ 13.98, 22.80, 27.55, 27.84, 29.31, 31.53, 32.50, 36.35,

[#] Prepared in 80% yield by conjugate addition (see reference 71) of butyl(phenylthio)copper to 3-bromo-5,5-dimethyl-2-cyclohexen-1-one, followed by reduction to the corresponding allylic alcohol using sodium borohydride and cerium(III) chloride heptahydrate in methanol.

38.06, 39.60, 40.04, 72.04, 127.32, 129.28, 131.12, 133.00; exact mass, *m/z* calcd for C₁₉H₂₆Cl₂Se 404.0577, found 404.0568. Anal. Calcd for C₁₉H₂₆Cl₂Se: C, 56.44; H, 6.48. Found: C, 56.68; H, 6.48.

3-Butyl-3-(chloromethyl)-5,5-trimethylcyclohexene (15d).

Triethylborane (1 M in hexane, 0.7 mL, 0.7 mmol) and then triphenyltin hydride (187 µL, 0.734 mmol) were added dropwise over about 1 min to a cold (0 °C) and stirred solution of 15c in dry hexane (6 mL).50 After 45 min at 0 °C, some starting material still remained (TLC control, silica, hexane). A further portion of triphenyltin hydride (60 µL, 0.235 mmol) was added, and stirring was continued for 15 min at 0 °C. At this point, no starting material remained (TLC control), and the mixture contained mainly the dichloride corresponding to the desired ring opening, with traces (<5%) of the monochloride 15d (VPC, 220 °C). Triphenyltin hydride (250 μL, 0.98 mmol) was added in one portion to the cold (0 °C) solution and the cold-bath was left The mixture was stirred for 14 h and the solvent was then evaporated. Flash chromatography of the residue over silica gel (2 x 21 cm) using hexane afforded the monochloride 15d (144 mg, 96%) as a colorless liquid: FT-IR (CHCl₃ cast) 2953, 1450, 747 cm⁻¹; ¹H NMR (CDCl₃, 300 MHz) δ 0.89 (t, J = 6.8 Hz, 3 H), 0.96 (s, 6 H), 1.10--1.60 (m, 8 H), 1.80 (dd, J = 4.0, 2.1 Hz, 2H), 3.46 (s, 2 H), 5.48 (dt, J = 10.2, 1.2 Hz, 1 H), 5.74 (dt, J = 10.2, 4.0 Hz, 1 H); 13 C NMR (CDCl₃, 75.5 MHz) & 14.13, 23.35, 25.66, 29.36, 29.72, 31.05, 38.34, 39.08,

39.61, 43.06, 53.01, 127.31, 130.14. Anal. Calcd for C₁₃H₂₃Cl: C, 72.70; H, 10.79. Found: C, 73.12; H, 10.78.

(1aα,2β,4aβ)-Decahydro-4a-methylcyclopropa[d]naphthalen-2-ol (16b).⁷²

A mixture of zinc powder (BDH Chemicals, 1.96 g, 30 mmol) and dry DME (10 mL), maintained under a static atmosphere of argon, and contained in a 100-mL round-bottomed flask equipped with a condenser, was sonicated⁷³ for 20 min at 55 °C. A mixture⁷² of alcohols 16a and 17a (in a ratio of 87:13, respectively) (500 mg, 3.0 mmol) was then added in one portion, followed by dropwise addition of diiodomethane over 15 min. Sonication was continued and, after a few min, an exothermic reaction began, causing the DME to reflux gently. Sonication was continued for 6 h after the diiodomethane had been added. [This experiment was done several times and, in some instances, heating at reflux for a few hours was necessary in order to complete the reaction.] The mixture was then diluted with ether (30 mL), followed by slow addition of saturated aqueous ammonium chloride (20 mL). The mixture was filtered through a pad of Celite (4.0 x 4.0 cm). The pad was washed with ether (3 X 20 mL) and the combined organic layers were washed with 5% w/v aqueous sodium thiosulfate (1 x 20 mL), water (1 x 20 mL), and brine (1 x 20 mL), dried (MgSO₄) and evaporated. Flash chromatography of the residue over silica gel (2 x 20 cm) using 20% ethyl acetate--hexane afforded 16b and 17b (372 mg, 68%) as a brownish solid, which

contained the two isomers in a ratio of 87:13 respectively [¹H NMR, (300 MHz)].

A mixture of 16b and 17b (87:13, about 2.4 g), obtained from a different experiment, was separated by chromatography over neutral alumina (grade III) (3.5 x 20 cm) using ether--benzene mixtures (2 to 20% ether--benzene). Pure 16b (1.7 g, 70% of the original mixture) and a mixture of 16b and 17b (20:80, respectively; 0.65 g, 30% of the original mixture) were obtained. We later found that the compounds could be separated more conveniently by flash chromatography over silica gel, using 12% ethyl acetate--hexane.

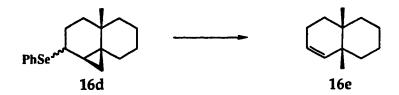

Alcohol 16b had: 1 H NMR (CDCl₃, 300 MHz) δ 0.08 (dd, J = 9.2, 4.7 Hz, 1 H), 0.55 (broad d, J = 13.5 Hz, 1 H), 0.62 (t, J = 4.9 Hz, 1 H), 0.90 (m, 1 H), 1.02 (s, 3 HI), 1.10--1.33 (m, 5 H), 1.48--1.79 (m, 6 H), 1.94 (dt, J = 13.0, 3.9 Hz, 1 H), 4.17 (broad t, J = 13.5 Hz, 1 H); 13 C NMR (CDCl₃, 75.5 MHz) δ 10.22, 22.36, 25.52, 25.58, 26.83, 27.46, 28.00, 30.29, 31.10, 34.66, 35.15, 63.85. The VPC retention times at 170 °C were 5.71 and 6.21 min for 16b and 17b, respectively.

 $(1a\alpha,2\alpha,4a\beta)$ - and $(1a\alpha,2\beta,4a\beta)$ -Decahydro-4a-methyl-2-(phenylseleno)-cyclopropa[d]naphthalene (16c).

The general method reported in the literature⁴³ was followed, but with some modifications. Phenylselenocyanate (511 mg, 2.79 mmol) in dry THF (1 mL) was added over 1 h to a cold (-78 °C), stirred solution of cyclopropyl alcohol **16b** (251 mg, 1.39 mmol) and tributylphosphine (695 µL, 2.79 mmol) in dry THF (4 mL). The cold-bath was left in place and stirring was continued for

12 h, during which time the mixture attained room temperature. Evaporation of the solvent and flash chromatography of the residue over silica gel (2 x 20 cm) using 4% ethyl acetate--hexane afforded a yellow oil consisting of 16c and diphenyl diselenide. This material was dissolved in a mixture of dry THF (8 mL) and absolute ethanol (2 mL), and the solution was cooled to -20 °C. Sodium borohydride (100 mg) was added in one portion. Bubbling was observed and the yellow coloration due to diphenyl diselenide disappeared. Stirring was continued for 5 min at -20 °C, and bromoacetic acid (500 mg) was added in one portion. The cold-bath was removed and the mixture was stirred for 1 h, and diluted with ether (30 mL). The reaction was quenched with saturated aqueous sodium bicarbonate (1 x 15 mL). The aqueous layer was extracted with ether (1 x 30 mL) and the combined organic extracts were washed successively with saturated aqueous sodium bicarbonate (1 x 15 mL), water (1 x 15 mL), and brine (1 x 15 mL), and dried (MgSO₄). Evaporation of the solvent and flash chromatography of the residue over silica gel (1.5 x 20 cm) using 0.5% ethyl acetate--hexane afforded a mixture of selenides 16c (366 mg, 82%) as a colorless oil: FT-IR (CHCl₃ cast) 2928, 1580, 740, 690 cm⁻¹; ¹H NMR (CDCl₃, 300 MHz) δ 0.27 (m, 2 H), 0.48 (dm, J = 13.5 Hz, 1 H), 0.99 (s, 3 H), 1.0--1.27(m, 6 H), 1.41--1.81 (m, 7 H), 1.86 (dt, J = 13.9, 3.5 Hz, 1 H), 3.41 (dd, J = 11.0, 7.4 Hz, 1 H), 7.21--7.32 (m, 3 H), 7.53--7.63 (m, 2 H); 13 C NMR (CDCl₃, 75.5 MHz) δ 18.04, 22.61, 25.57, 25.61, 25.80, 27.43, 27.91, 30.28, 35.32, 35.89, 39.46, 126.95, 128.91, 130.53, 133.81; exact mass, m/z calcd for C₁₈H₂₄Se, 320.1043, found 320.1040. Anal. Calcd for C₁₈H₂₄Se: C, 67.70; H, 7.57. Found: C, 68.21; H, 7.55.

Cis-1,2,3,4,4a,5,6,8a-Octahydro-4a,8a-dimethylnaphthalene (16d).

(a) Photochemical method. The general photochemical method for radical ring opening was followed using the selenides 16c (57 mg, 0.178 mmol) in dry hexane (0.9 mL), and tributyltin hydride (72 μ L, 0.267 mmol). The mixture was stirred and irradiated for 2 h at -5 °C to 5 °C, and evaporated. Flash chromatography of the residue over silica gel (1 x 20 cm) using hexane afforded, after careful evaporation of the solvent, an oil (26.0 mg). Kugelrohr distillation (80 °C, 15 mm) (to effect complete removal of solvent) gave 16d (25 mg, 84%) as a colorless oil: FT-IR (CHCl₃ cast) 2970, 2923, 2859, 1650 cm⁻¹; H NMR (CDCl₃, 300 MHz) δ 0.87 (s, 3 H), 0.88 (s, about 3 H), 1.05-1.55 (m, 10 H), 2.0 (m, 2 H), 5.28 (dt, J = 10.0, 2.0 Hz, 1 H), 5.51 (dt, J = 10.0, 3.4 Hz, 1 H), 5.55--5.72 [m, 0.12 H (from an olefinic byproduct, which amounted to 6% of the total)]; ¹³C NMR (CDCl₃, 75.5 MHz) δ 22.20, 22.79, 23.25, 23.33, 33.80, 37.18, 37.48, 124.00, 131.57, 138.15; exact mass, m/z calcd for C₁₂H₂₀ 164.1565, found 164.1562.

The ¹H NMR spectrum shows that the oil contains the desired material (93%), an olefinic byproduct (6%), and the product of reduction without ring opening (1%). The ¹H NMR chemical shifts of 16d were identical with those reported for material synthesized⁷⁴ by another route. We are not certain if the ¹³C NMR signals at 124.00 and 131.57 correspond to 16d or to the olefinic byproduct.

[#] The evaporation was done at 25 °C under water pump vacuum, and the residual oil was kept under water pump vacuum for a maximum of 2 min.

(b) Thermal method using triethylborane. Tributyltin hydride (328 μL, 1.22 mmol) and then triethylborane (1M in hexanes, 121 μL, 0.121 mmol) were each added in one portion to a cooled (-5 °C) and stirred solution of selenides 16c in dry hexane (2 mL), and then air (12 mL) was injected into the solution over a period of 2 h (syringe pump). Carbon tetrachloride (0.5 mL) was then injected and the solvent was evaporated. The residue was processed as described above and gave 16d (58 mg, 85%) as a colorless oil, whose ¹H NMR spectrum showed the desired material 16d (97%), the olefinic byproduct (2%) and product of reduction without ring opening (1%).

 2α , 3, 4, 4a, 5, 6, 7, 8-Octahydro-4a β -methyl-2-naphthol (17a).

(a) 2α-(Benzoyloxy)-2α,3,4,4a,5,6,7,8-Octahydro-4aβ-methylnaphthalene. Triphenylphosphine (4.74 g, 18.08 mmol) and then benzoic acid (2.21 g, 18.08 mmol) were each added in one portion to a magnetically stirred solution of 16a and 17a (in a ratio of 87:13, respectively) (1.5 g, 9.04 mmol) in dry THF (70 mL). Diethylazodicarboxylate (2.84 mL, 18.08 mmol) in dry THF (20 mL) was then injected over 30 min (syringe pump). After the addition, the mixture was stirred for 1 h, evaporated, and diluted with dichloromethane (250 mL). The organic layer was washed with saturated aqueous sodium bicarbonate (1 x 100 mL), water (1 x 100 mL), and brine (1 x 100 mL), and dried (MgSO₄). Evaporation of the solvent and flash chromatography of the residue over silica gel (6 x 18 cm) using 25% dichloromethane--hexane afforded a

chromatographically inseparable (TLC) mixture of benzoates [in a ratio of 21:79; 1 H NMR (200 MHz)] (2.06 $_{\odot}$, 82%) as a colorless oil: IR (neat) 2925, 1705, 1270, 1108, 718 cm⁻¹; 1 H NMR (CDCl₃, 300 MHz) δ 1.09 (s, 2.36 H), 1.16 (s, 0.64 H), 1.20--2.13 (m, 13 H), 2.13--2.29 (m, 1 H), 5.35--5.41 (m, 1 H), 5.50--5.56 (m, 1 H), 7.38--7.46 (m, 2 H), 7.50--7.57 (m, 1 H), 8.02--8.09 (m, 2 H); 13 C NMR (CDCl₃, 75.5 MHz) (major isomer) δ 22.11, 22.84, 25.04, 27.88, 32.36, 35.02, 41.74, 68.68, 117.39, 128.23, 129.58, 131.10, 132.61, 151.02, 166.30; (minor isomer) δ .22.28, 23.81, 24.93, 28.42, 37.02, 41.92, 71.46, 119.19, 128.23, 129.58, 130.86, 132.68, 148.76, 166.45.

(b) 2α,3,4,4a,5,6,7,8-Octahydro-4aβ-methyl-2-naphthol (17a). A mixture of the above benzoates (2.07 g, 7.67 mmol) in methanol (80 mL) and 20% w/v aqueous sodium hydroxide (7 mL) was stirred at room temperature for 5 h, quenched with saturated aqueous ammonium chloride (50 mL), and concentrated. The residue was extracted with ether (150 mL) and the organic extract was washed with water (2 x 25 mL), and brine (1 x 25 mL), and dried (MgSO₄). Evaporation of the solvent and flash chromatography of the residue over silica gel (3 x 22 cm) using 20% ethyl acetate--hexane afforded 17a and 16a (1.17 g, 92%) as a colorless oil which was a mixture of the isomers [1H NMR (300 MHz)] in a 79:21 ratio, respectively: 1 H NMR (CDCl₃, 300 MHz) δ 1.02 (s, 2.49 H), 1.10 (s, 0.51 H), 1.11-2.52 (m, 14 H), 4.02-4.12 (m, 0.87 H), 4.14-4.22 (m, 0.13 H), 5.26-5.31 (m, 0.13 H), 5.42 (d, J = 4.2 Hz, 0.83 H); 13 C NMR (CDCl₃, 75.5 MHz) (major isomer only) δ 22.08, 22.94, 27.90, 32.27, 34.37, 34.99, 41.45, 64.65, 121.46, 148.28.

 $(1a\beta,2\alpha,4a\beta)$ -Decahydro-4a-methyl-cyclopropa[d]naphthalen-2-ol (17b).

The procedure described for 16b was followed using zinc powder (6.96 g, 107.4 mmol) in dry DME (40 mL), a mixture⁷⁵ of 17a and 16a (17a:16a::79:21) (1.78 g, 10.74 mmol), and diiodomethane (3.03 mL, 37.6 mmol), except that, after sonication at 55 °C for 6 h, more zinc powder (1.39 g, 21.4 mmol) and diiodomethane (0.86 mL, 10.74 mmol) were added, followed by refluxing for 30 min, and sonication for 6 h at 55 °C. This modification was necessary to ensure complete reaction. Flash chromatography over silica gel (3 x 20 cm) using 20% ethyl acetate--hexane afforded 17b and 16b (1.58 g, 82%) as a mixture of isomers in a 79:21 ratio, respectively [1H NMR (300 MHz)]. The mixture was separated by flash chromatography over silica gel using 12% ethyl acetate--hexane. Alcohol 17b had: FT-IR (CHCl₃ cast) 3375, 2922, 2859, 1484, 1056 cm⁻¹ ¹H NMR (CDCl₃, 300 MHz) δ 0.10 (dd, J = 8.6, 4.7 Hz, 1 H), 0.52 (dm, J = 13.2 Hz, 1 H), 0.73 (m, 1 H), 0.99--1.09 (m, including a singlet at 1.03, 4 H), 1.11--1.71 (m, 11 H), 1.88--2.03 (m, 2 H), 4.36 (m, 1 H); ¹³C NMR (CDCl₃, 75.5 MHz) δ 10.88. 22.14, 22.22, 25.37, 26.44, 27.30, 30.11, 30.95, 33.01, 33.43, 38.80, 64.61; exact mass, m/z calcd for C₁₂H₂₀O 180.1514, found 180.1514.

 $(1a\alpha,2\beta,4a\alpha)$ - and $(1a\alpha,2\alpha,4a\alpha)$ -Decahydro-4a-methyl-2-(phenylseleno)-cyclopropa[d]naphthalene (17c).

The procedure described for selenide 16c was followed using alcohol 17b (240 mg, 1.39 mmol) in dry THF (4.5 mL), tributylphosphine (690 μL, 2.78 mmol), and phenylselenocyanate (510 mg, 2.78 mmol) in dry THF (0.5 mL). Diphenyl diselenide was removed as described for 16c, using sodium borohydride (100 mg) and bromoacetic acid (500 mg). After workup, flash chromatography of the residue over silica gel (2 x 20 cm) using 1% ethyl acetate--hexane afforded a mixture of selenides 17c (304 mg, 72%) as a slightly yellow oil. The material, which contained the isomers in a ratio of 75:25, based on ¹H NMR (300 MHz) signals at δ 3.65 and 4.06, had: FT-IR (CHCl₃ cast) 2925, 1580, 1477, 1437, 758, 691 cm⁻¹; ¹H NMR (CDCl₃, 300 MHz) (major isomer only) δ 0.21 (dd, J = 9.2, 4.8 Hz, 1 H), 0.43 (m, 2 H), 0.93--1.88 (m, including a singlet at 1.09, 13 H), 1.97 (ddt, J = 8.6, 3.6, 2.1 Hz, 1 H), 3.67 (t, J = 9.2 Hz, 1 H), 7.30 (m, 3 H), 7.61 (m, 2 H); ¹³C NMR (CDCl₃, 75.5 MHz) δ 17.79, 21.88, 22.01, 25.26 (two coincident signals), 30.45, 30.85, 33.09, 35.22, 37.68, 38.45, 17 97, 128.91, 130.92, 133.80; exact mass, m/z calcd for $C_{18}H_{24}Se$ 320.1043, found **320.1042.** Anal. Calcd for C₁₈H₂₄Se: C, 67.70; H, 7.57. Found: C, 67.31; 7.51.

Attempted Preparation of Trans-1,2,3,4,4a,5,6,8a-Octahydro-4a,8a-dimethylnaphthalene (17d).

(a) Thermal procedure. The general procedure for thermal radical ring opening was followed using selenides 17c (60 mg, 0.187 mmol) in benzene (0.5 mL), triphenyltin hydride (72 μ L, 0.28 mmol), AIBN (3 mg, 0.02 mmol) and a reaction time of 15 min. Flash chromatography of the crude product over

silica gel (1 x 15 cm) using hexane afforded a mixture of hydrocarbons (26.2 mg) containing a compound tentatively identified as 32 [~ 70 mol%, 1 H NMR (300 MHz)] as the major component, and unidentified olefinic byproducts: 1 H NMR (CDCl₃, 300 MHz) and characteristic peaks of the major component only) δ 0.04 (dd, J = 9.0, Lo ru 1 H), 0.36–0.45 (m, 2 H), 0.68 (m, 1 H), 1.10 (s, 3 H), 1.93 (m, 2 H); (minor component) δ 5.40 (broad s); 13 C NMR (CDCl₃, 75.5 MHz) (major component only) δ 15.12, 15.79, 18.11, 20.29, 21.99, 22.41, 25.59, 33.52, 34.79, 39.40.

(b) Photochemical procedure. The general photochemical method for radical ring opening was followed except that the stannane was added slowly: Triphenyltin hydride (80 μL, 0.234 mmol) in dry THF (0.2 mL) was added over 45 min (svringe pump) to a cold (-70 °C) and stirred solution of 17c in dry THF (0.2 mL). Stirring and irradiation were continued at -70 °C to -10 °C for 45 min, and then at 0 °C for 45 min. Flash chromatography of the crude product over silica gel (1 x 15 cm) using hexane afforded 23 mg of a mixture of hydrocarbons (23 mg) containing 32 [> 80 mol%, ¹H NMR (300 MHz)] as the major component, along with one unidentified olefinic compound.#

The olefinic byproduct from the attemted preparation of **17d** had: 1 H NMR (CDCl₃, 300 MHz) δ 0.15--0.24 (m, 1 H), 0.96 (d, J = 6.2 Hz, 3 H), 1.13 (s, 9 H), 1.39--1.47 (m, 1 H), 2.17 (d, J = 16.4 Hz) and 2.24 (t, J = 6.4 Hz) [both signals together correspond to 3 H], 2.45 (dd, J = 16.4, 7.2 Hz, 1 H), 3.67 (tm, J = 7.2 Hz, 2 H), 5.48--5.51 (broad m, 1 H), 7.31--7.48 (m, 6 H), 7.59--7.72 (m, 4 H); 13 C NMR (CDCl₃, 75.5 MHz) δ 17.27, 19.22, 23.89, 24.49, 26.89, 31.91, 34.07, 38.51, 63.15, 127.62, 128,46, 134.08, 135.61, 139.74.

[#] No significant change in the product ratio was observed when the addition of the stannane was done at 0 $^{\circ}$ C instead of -70 $^{\circ}$ C.

(15α,16α)-15,16-Dihydxo-3-methoxy-3'*H*-cycloprop[15,16]estra-1,3,5(10),15-tetraen-17-one (18b).

Treatment of the pure unsaturated ketone 18a with trimethylsulfoxonium iodide and sodium hydride according to the literature method, 76 followed by flash chromatography when store gel using 20% ethyl acetate—hexane, gave the cyclopropane 18b (72%): FT-IR (CH₂Cl₂ cast) 2948, 1710, 1611, 1498, 1282, 1253, 1043, 889 cm⁻¹; ¹H NMR (CDCl₃, 300 MHz) δ 1.0 (s, 3 H), 1.17 (m, 1 H), 1.45--1.88 (m, 8 H), 2.05 (m, 1 H), 2.13--2.24 (m, 2 H), 2.24-2.43 (m, 2 H), 2.96 (m, 2 H), 3.78 (s, 3 H), 6.66 (d, J = 2.8 Hz, 1 H), 6.71 (dd, J = 8.5, 2.8 Hz, 1 H), 7.17 (d, J = 8.5 Hz, 1 H); exact mass, m/z calcd for C₂₀H₂₄O₂ 296.1777, found 296.1776.

(15 α ,16 α ,17 β)-15,16-Dihydro-3-methoxy-3'H-cycloprop[15,16]estra-1,3,5(iii),15-tetraen-1 (18c).

Treatment of the cyclopropyl ketone with lithium aluminum hydride according to the literature method,⁷⁶ followed by flash chromatography over silica gel using 30% ethyl acetate- hexane gave pure cyclopropyl alcohol 18c

(90%): 1 H NMR (CDCl₃, 200 MHz) δ 0.3 (dd, J = 14.0, 8.3 Hz, 1 H), 0.82, (s, 3 H), 0.98 (m, 1 H), 1.17--1.65 (m, 8 H), 1.73--1.89 (m, 2 H), 2.07--2.37 (m, 3 H), 2.92 (m, 2 H), 3.78 (s, 3 H), 4.10 (m, 1 H), 6.65 (d, J = 3.2 Hz) and 6.7.3 (dd, J = 8.4, 3.2 Hz) [both signals together correspond to 2 H], 7.18 (d, J = 8.4 Hz, 1 H).

(15α,16α)-15,16-Dihydro-3-methoxy-17-(phenylseleno)-3'*H*-cycloprop[15,16]estra-1,3,5(10),15-tetraene (18d).#

Tributylphosphine (83 μL, 0.334 mmol) was added dropwise over 1 min a stirred solution of phenylselenocyanate(61 mg, 0.334 mmol) and cyclopropyl alcohol 18c⁷⁶ (50 mg, 0.167 mmol) in dry THF (0.6 mL). Stirring was continued for 4 h and another portion of phenylselenocyanate (30 mg, 0.16 mmol) and of tributylphosphine (42 μL, 0.0.16 mmol) were added. The mixture was stirred for 12 h at room temperature and was then diluted with dichloromethane (20 mL) and water (5 mL). The organic layer was washed with brine (1 x 5 mL), and dried (MgSO4). Evaporation of the solvent and flash chromatography of the residue over silica gel (1.2 x 15 cm) using 30% dichloromethane--hexane gave 18d (59 mg, 80%) as a gummy solid free of diphenyl diselenide: FT-IR (CHCl₃ cast) 2920, 1605, 1578, 1500, 1255, 1039,737 cm⁻¹; ¹H NMR (CDCl₃, 200 MHz) δ 0.35 (dd, J = 14.0, 8.2 Hz, 1 H), 0.95 (m, including a singlet at 1.0, 4 H), 1.38--1.72 (m, 6 H), 1.90 (dt, J = 12.5, 3.2 Hz, 1 H),

Stereochemistry at C(17) was not determined

2.03–2.38 (m, 4 H), 2.93 (m, 2 H), 4.78 (s, 1 H), 7.66 (d, J = 3.2 Hz) and 7.71 (dd, J = 8.4, 3.2 Hz) [both signals together correspond to 2 H], 7.16 (d, J = 8.4 Hz, 1 H), 7.28 (m, 3 H), 7.60 (m, 2 H); 13 C NMR (CDCl₃, 75.5 MHz) δ 11.03, 18.31, 20.88, 26.74, 26.85, 28.55, 29.76, 37.43, 41.25, 41.91, 44.08, 52.39, 55.19, 57.61, 11.35, 113.86, 125.95, 126.68, 128.97, 131.26, 132.76, 133.28, 137.90, 157.50; exact mass, m/z calcd for C₂₆H₃₀OSe 438.1462, found 438.1459. Anal. Calcd for C₂₆H₃₀OSe: C, 71.38; H, 6.91; O, 3.66. Found: C, 71.53; H,6.88; O, 3.69.

In a similar experiment, done on a larger scale (593 mg of starting material), the selenide was obtained in 75% yield.

(15β) -3-Methoxy-15-methylestra-1,3,5(10),16-tetraene (18e).

The general photochemical method for radical ring opening was followed using cyclopropyl selenide 18d (275 mg, 0,981 mmol) in toluene (5.0 mL) and tributyltin hydride (396 μ L, 1.47 mmol). The mixture was stirred and irradiated for 2.5 h at 0 °C. Evaporation of the solvent and flash chromatography of the residue over silica gel (1.5 × 15 cm) using 20% dichloromethane--hexane gave 18e (167 mg, 94%; 79% after correction for the fact that the material is contaminated [¹H NMR (200 MHz)] with 16 mol% of the ring expansion product 18f as a white semi-solid: FT-IR (CHCl₃ cast) 3033, 1610, 1575, 1533, 1256, 1237, 1042, 762 cm⁻¹; ¹H NMR (CDCl₃, 300 MHz) δ 0.89 (s, 0.6 H), 0.99 (s) and 1.01 (d, J = 7.2 Hz) [both signals together correspond to 4.8

H], 1.15--1.38 (m, 0.9 H), 1.40--1.92 (m, 5.8 H), 2.08 (m, 1.4 H), 2.28 (m, 2 H), 2.65 (dd of quintets, J = 7.2, 2.9, 1.1 Hz, 0.83 H), 2.80--3.02 (m, 2 H), 3.76 (s, 3 H), 5.50 (s, 0.34 H), 5.77 (dd, J = 5.9, 3.0 Hz, 0.83 H), 5.87 (dd, J = 5.9, 1.5 Hz, 0.83 H), 6.67 (d, J = 3.2 Hz) and 6.70 (dd, J = 8.4, 3.2 Hz) [both signals together correspond to 2 H], 7.19 (d, J = 8.4 Hz, 1 H); ¹³C NMR (CDCl₃, 75.5 MHz) (major isomer) δ 14.90, 22.87, 26.17, 27.67, 29.68, 35.50, 37.86, 39.06, 45.17, 46.41, 55.17, 56.04, 111.20, 113.85, 125.69, 133.50, 135.28, 138.00, 142.08, 157.48; (minor isomer) δ 20.00, 20.22, 26.25, 26.36, 26.42, 30.16, 34.72, 38.55, 44.08, 47.36, 111.49, 113.49, 123.69, 126.15, 133.23, 139.50, 157.47; exact mass, m/z calcd for $C_{20}H_{26}O$ 282.1984, found 282.1977.

The results were slightly different when the reaction was done with triphenyltin hydride at -30 °C (16% ring expansion) or in refluxing benzene (with triphenyltin hydride) (22% ring expansion).

(17α) -3-Methoxyestra-1,3,5(10),15-tetraen-17-ol (196).

(a) (17β) -3-Methoxyestra-1,3,5(10),15-tetraen-17-ol.

Cerium(III) chloride heptahydrate⁷⁷ (1.58 g, 4.25 mmol) was added in one portion to a cooled (-23 °C) and stirred suspension of 19a (0.98 g, 3.54 mmol) in dry methanol (18 mL) and dry THF (4 mL). Sodium borohydride (161 mg, 4.25 mmol) was then added in portions ever 5 min. Stirring was continued for 30 min at -23 °C. The cold-bath was replaced by an ice bath and, after 30 min, this was removed. Stirring was continued for an additional 45

min. The mixture was diluted with dichloromethane (20 mL) and quenched with saturated aqueous ammonium chloride (10 mL). The aqueous layer was extracted with dichloromethane (1 x 20 mL) and the combined organic extracts were washed with water (1 x 10 mL), and brine (1 x 10 mL), and dried (MgSO4). Evaporation of the solvent and flash chromatography of the residue over silica gel (3 x 20 cm) using 5% ethyl acetate--dichloromethane gave the desired alcohol⁷⁶ (969 mg, 98%) as a white solid: FT-IR (CHCl₃ cast) 3460, 2927, 1605, 1502, 1237, 1037 cm⁻¹; ¹H NMR (CDCl₃, 400 MHz) δ 0.86 (s, 3 H), 1.40--1.51 (m, 1 H), 1.53--1.73 (m, 4 H), 1.98--2.13 (m,3 H), 2.23--2.39 (m, 2 H), 2.91 (m, 2 H), 3.78 (s, 3 H), 4.41 (broad s, 1 H), 5.73 (ddd, J = 5.9, 3.1, 1.3 Hz, 1 H), 6.04 (broad d, J = 5.9 Hz, 1 H), 6.65 (d, J = 2.5 Hz, 1 H), 6.72 (dd, J = 8.5, 2.5 Hz, 1 J = 8.5 Hz, 1 H); ¹³C NMR (CDCl₃, 75.5 M/sz) δ 12.24, 26.14, 27.64, 74, 36.42, 44.43, 51.36, 55.24, 56.76, 85.72, 111.50, 113.92, 126.13, 131.61, 132.58, 134.68, 137.87, 157.57; exact mass, m/z calcd for C₁₉H₂₄O₂ 284.1777, found 284.1778.

(b) (17α)-3-Methoxyestra-1,3,5(16),15-tetraen-17-yl benzoate. Triphenylphosphine (1.74 g, 6.6 mmol) and benzoic acid (806 mg, 6.6 mmol) were added successively to a magnetically stirred solution of the above alcohol (940 mg, 3.31 mmol) in dry THF (27 mL). Diethyl azodicarboxylate (1.04 mL, 6.6 mmol) in dry THF (6 mL) was then added dropwise over 30 min and stirring was continued for 2 h.⁷⁸ At this point, the reaction was still incomplete (TLC control, silica, 30% ethyl acetate--hexane). Further portions of triphenylphosphine (1.74 g, 6.6 mmol), benzoic acid (806 mg, 6.6 mmol) and diethyl azodicarboxylate (1.04 mL, 6.6 mmol) were then added and, after an additional 1 h the solvent was evaporated and the residue was taken up in dichloromethane (150 mL). The solution was washed with saturated aqueous sodium bicarbonate (1 x 50 mL), water (1 x 50 mL), and brine (1 x 50 mL), and

dried (MgSO₄). Evaporation of the solvent and flash chromatography of the residue over silica gel (4 × 20 cm) using 25 % ethyl acetate--hexane gave the desired benzoate (1.10 g, 86%) as a gummy solid which contained slight impurities (TLC): FT-IR (CHCl₃ cast) 2920, 1713, 1500, 1270, 1256, 705 cm⁻¹; ¹H NMR (CDCl₃, 300 MHz) δ 1.02 (s, 3 H), 1.20--2.03 (m, 5 H), 2.13 (m, 1 H), 2.35 (m, 1 H), 2.69 (ddd, J = 11.5, 3.3, 1.7 Hz, 1 H), 2.92 (m, 2 H), 3.77 (s, 3 H), 5.39 (d, J = 2.6 Hz, 1 H), 6.08 (quintet, J = 3.0 Hz, 1 H), 6.39 (dd, J = 5.9, 1.3 Hz, 1 H), 6.65 (d, J = 2.2 Hz, 1 H), 6.72 (dd, J = 2.2 Hz, 1 H), 7.21 (d, J = 8.5 Hz, 1 H), 7.43 (m, 2 H), 7.53 (m, 2 H), 8.05 (m, 2 H); ¹³C NMR (CDCl₃, 75.5 MHz) δ 19.24, 25.75, 28.16, 29.60, 31.06, 36.09, 44.41, 46.24, 55.21, 56.14, 84.57, 111.52, 113.90, 126.09, 128.36, 129.61, 129.78, 130.79, 132.50, 132.80, 137.78, 139.58, 157.60, 166.47; exact mass, m/z calcd for C₂₆H₂₈O₃ 388.2038, found 388.2033.

(c) (17 α)-3-Methoxyestra-1,3,5(10):15-tetraen-17-ol (19b).⁷⁹ Methanol (21 mL) and 20% w/v aqueous sodium experiencide (9 mL) were added to a magnetically stirred solution of the above benzoate (1.06 g, 2.73 mmol) in THF (7 mL). Stirring was continued for 16 h and the mixture was then quenched with saturated aqueous ammonium chloride (15 mL). Most of the THF was evaporated (water pump vacuum) and the residue was extracted with dichloromethane (1 x 100 mL). The organic phase was washed with water (2 x 20 mL), and brine (1 x 20 mL), and dried (MgSO4). Evaporation of the solvent and flash chromatography of the residue over silica gel (3 x 15 cm) afforded 19b (592 mg, 76%) as a white solid: FT-IR (CHCl₃ cast) 3300, 2929, 1610, 1501, 1258, 1046, 1053 cm⁻¹; ¹H NMR (CDCl₃, 300 MHz) δ 0.84 (s, 3 H), 1.42--1.75 (m, 5 H), 1.96 (m, 1 H), 2.10 (m, 1 H), 2.28 (dt, J = 10.5, 4.4 Hz, 1 H), 2.36--2.53 (m, 2 H), 2.90 (m, 2 H), 3.78 (s, 3 H), 4.15 (broad d, J = 2.0 Hz, 1 H), 6.0 (m, 1 H), 6.22 (dd, J = 4.2, 1.4 Hz, 1 H), 6.63 (d, J = 2.8 Hz, 1 H), 6.72 (dd, J = 8.5, 2.8 Hz, 1 H), 7.21 (d, J = 8.5 Hz, 1 H); ¹³C NMR (CDCl₃, 75.5 MHz) δ 19.50, 25.75, 28.19, 29.58, 30.56,

36.04, 44.46, 46.15, 54.80, 55.20, 82.47, 111.45, 113.89, 126.06, 132.68, 133.19, 137.20, 137.79, 157.50; exact mass, *m*/*z* calcd for C₁₉H₂₄O₂ 284.1777, found 284.1777. Anal. Calcd for C₁₉H₂₄O₂: C, 80.24; H, 8.51. Found: C, 79.95; H, 8.52.

 $(15\beta,16\beta,17\alpha)$ -15,16-Dihydro-3-methoxy-3'*H*-cycloprop[15,16]estra-1,3,5(10),15-tetraen-17-ol (19c).

The procedure is based on a literature method. 80 Allylic alcohol 19b (200 mg, 0.7 mmol) and then dry ether (5 mL) were added to a suspension of zinc-copper couple (436 mg, 6.7 mmol)⁸¹ in dry DME (5 mL) maintained under a static atmosphere of argon in a 25-mL round-bottom-flask equipped with a condenser. Diiodomethane (324 μL, 4.02 mmol) was then added dropwise and the mixture was stirred at reflux temperature (oil bath at 60 °C) for 18 h. At this point the reaction was still incomplete (TLC, silica, 30% ethyl acetate--hexane). Zinc-copper couple (218 mg, 3.3 mmol) and then diiodomethane (162 μL, 2.01 mmol) were added and the mixture was stirred at reflux temperature for an additional 18 h. Saturated aqueous ammonium chloride (10 mL) was added followed by ethyl acetate (10 mL). The resulting slurry was filtered through a pad of Celite (2.0 x 2.0 cm) and the pad was washed with ethyl acetate (5 x 6 mL). The organic filtrate was washed with water (1 x 10 mL), saturated aqueous sodium bicarbonate (1 x 10 mL), water (1 x 10 mL), and brine (1 x 10 mL), and dried (MgSO4). Evaporation of the

solvent and flash chromatography of the residue over silice 3el (1.5 x 20.0 cm) using 20% ethyl acetate--hexane afforded 19c (171 mg, 81%; 86% based on conversion) and starting material 19b (11 mg). Compound 19c had: FT-IR (CHCl₃ cast) 3440, 1600, 1570, 1255, 1230, 1042 cm⁻¹; ¹H NMR (CDCl₃, 300 MHz) δ 0.9--1.08 (m, including a singlet at 0.95, 6 H), 1.20--1.80 (m, 8 H), 2.13 (m, 2 H), 2.28 (m, 1 H), 2.88 (m, 1 H), 3.77 (s, 3 H), 3.96 (d, J = 5,5 Hz, 1 H), 6.64 (d, J = 2.8 Hz, 1 H), 6.70 (dd, J = 8.5, 2.8 Hz, 1 H), 7.20 (d, J = 8.5 Hz, 1 H); ¹³C NMR (CDCl₃, 75.5 MHz) δ 19.31, 19.32, 21.12, 25.32, 25.85, 28.78, 29.92, 30.47, 37.98, 43.96, 54.66, 55.21, 56.14, 77.99, 111.41, 113.88, 126.24, 132.78, 138.12, 157.45, 180.97; exact mass, m/z calcd for C₂₀H₂₆O₂ 298.1933, found 298.1933. Anal. Calcd for C₂₀H₂₆O₂: C, 80.49; H, 8.78. Found: C, 80.26; H, 8.94.

(15β,16β)-15,16-Dihydro-3-methoxy-17-(phenylseleno)-3'*H*-cycloprop[15,16]estra-1,3,5(10),15-tetraene (19d).#

Tributylphosphine (0.41 mL, 334 mg, 1.65 mmol) was added to a stirred solution of **19c** (214 mg, 0.72 mmol) in dry THF (4 mL) at 50 °C contained in a 10-mL round-bottomed flask equipped with a condenser. Phenylselenocyanate (303 mg, 1.65 mmol) in dry THF (0.8 mL) was then added over 3 h

[#] Stereochemistry at C(17) was not determined.

(syringe pump) via the condenser, and stirring was continued for 12 h. The mixture was allowed to cool to room temperature and the solvent was evaporated. Flash chromatography of the residue over silica gel (2 x 20.0 cm) using 25% dichloromethane--hexane gave 19d (197 mg, 63%) as a viscous oil: FT-IR (CHCl₃ cast) 2930, 1620, 1590, 1500, 1260, 1050, 740 cm⁻¹; 1 H NMR (CDCl₃, 300 MHz) δ 0.63 (dd, J = 7.8, 3.7 Hz, 1 H), 0.82 (dd, J = 11.0, 5.1 Hz, 1 H), 1.12 (s, 3 H), 1.2-1.93 (m, 8 H), 2.21 (m, 3 H), 2.75 (d, J = 4.8 Hz, 1 H), 2.91 (m, 2 H), 3.80 (s, 3 H), 6.67 (d, J = 2.8 Hz, 1 H), 6.73 (dd, J = 8.5, 2.8 Hz, 1 H), 7.11--7.32 [m, including a doublet at 7.20 (J = 8.5 Hz), 4 H], 7.60 (m, 2 H); 13 C NMR (CDCl₃, 75.5 MHz) (major peaks only) δ 17.20, 20.74, 26.02, 27.15, 27.25, 28.54, 29.81, 35.63, 38.21, 44.34, 55.13, 57.34, 57.91, 60.16, 111.40, 113.85, 126.16, 128.90, 132.04, 132.13, 132.52, 138.03, 157.52; exact mass, m/z calcd for C_{26} H₃₀OSe 438.1462, found 438.1460. Anal. Calcd for C_{26} H₃₀OSe: C, 71.38; H, 6.91; Ω , 3.66. Found: C, 71.28; H, 6.92; Ω , 3.95.

(15α) -3-Methoxy-15-methylestra-1,3,5(10),16-tetraene (19e).

The general photochemical method for radical ring opening was followed using tributyltin hydride (110 μ L, 0.411 mmol), which was added to a cold (0 °C) solution of 19d (115 mg, 0.262 mmol) in dry toluene (2.8 mL). The mixture was stirred and irradiated at 0-20 °C for 3 h. At this point, the reaction was still incomplete (TLC control, silica, 5% ethyl acetate--hexane).

Tributyltin hydride (44 µL, 0.164 mmol) was added at 0 °C and the mixture was stirred and irradiated at 0-25 °C for 1 h. Evaporation of the solvent and flash chromatography of the residue over silica gel (2 x 15 cm) using 20% dichloromethane--hexane gave a mixture of 19e and 19f in a ratio [1H NMR (300 MHz)] of 84:16, respectively (64 mg, 86%): FT-IR (CHCl₃ cast) 2928, 1610, 1575, 1501, 1256, 1240 cm⁻¹; ¹H NMR (CDCl₃, 300 MHz) 0.83 (s, 2.6 H), 0.90 (s, 0.4 H), 1.10--1.42 [m, including a doublet at 1.17 (J = 7.1 Hz), 4 H], 1.42--1.95 (m, 5 H), 2.12 (dm, J = 12.5 Hz, 1.72 H), 2.32 (m, 3 H), 2.57 (quintet, J = 7.5 Hz, 0.86 H), 2.78-3.01 [m, including a doublet at 2.88 (J = 6.5 Hz), 2 H], 3.78 (s, 3 H), 5.45(d, J = 5.5 Hz, 0.86 H), 5.50 (broad s, 0.28 H), 5.81 (dd, J = 5.5, 2.2 Hz, 0.86 H), 6.62 (d, I = 2.9 Hz, 1 H), 6.71 (dd, J = 8.6, 2.9 Hz, 1 H), 7.13--7.26 [m, including a]doublet at 7.19 (J = 8.6 Hz)], 1 H] 13 C NMR (CDCl₃, 75.5 MHz) (major isomer) δ 18.97, 20.48, 27.24, 28.58, 30.04, 36.38, 38.43, 39.86, 44.91, 47.97, 55.21, 62.85, 111.55, 113.67, 126.37, 133.00, 136.72, 137.76, 141.53, 157.41; (minor isomer) δ . 20.04, 20.25, 26.26, 26.44, 30.21, 34.76, 38.59, 39.14, 44.12, 47.40, 113.53, 123.94, 126.21, 139.54; exact mass, m/z calcd for $C_{20}H_{26}O$ 282.1982, found 282.1978. Anal. Calcd for C₂₀H₂₆0: C, 85.05; H, 9.21. Found: C, 85.03; H, 9.44.

3-Methoxy-D-homoestra-1,3,5(10),17-tetraene (18f=19f).⁵³

Freshly prepared potassium graphite (C₈K) (3.98 g, 29.4 mmol) and titanium trichloride (2.18 g, 14.19 mmol) were weighed under argon in a glove box and transferred successively to a 250-mL round-bottomed flask equipped with a condenser and containing dry diglyme (60 mL). The mixture was stirred at 85 °C for 2 h under argon. 3-Methoxy-D-homoestra-1,3,5(10)triene- 17α , $17a\beta$ -diol 30^{54} (267 mg, 0.84 mmol) was added via the condenser in one portion into the stirred slurry of titanium reagent, and the inside of the condenser was rinsed with dry diglyme (5 mL). Stirring was continued at 150 °C for an arbitrary period of 36 h. T : mixture was cooled to room temperature and filtered under a blanket of argon through a pad of Florisil (11 x 4 cm) contained in a sintered funnel equipped with an argon inlet near the top. The column was washed with dichloromethane (400 mL) and ether (200 mL). Evaporation of the filtrate, removal of diglyme by Kugelrohr distillation (80 °C, 3 mm) and flash chromatography of the residue over silica gel (2.5 x 20.0 cm) using "% ethyl acetate--hexane gave 18f (219 mg, 92%) as a white solid: FT-IR (CHCl₃ cast) 2925, 1600, 1500, 1218, 759 cm⁻¹; ¹H NMR (CDCl₃, 300 MHz) δ 0.82--0.98 (m, including a singlet at 0.91, 4 H), 1.20--1.69 (m, 10 H), 1.81--1.95 (m, 1 H), 2.0--2.22 (m, 3 H), 2.22--2.39 (m, 2 H), 2.82--2.93 (m, 2 H), 3.79 (s, 3 H), 5.51 (broad singlet, 2 H), 6.64 (d, J = 2.8 Hz, 1 H), 6.72 (dd, J = 8.4, 2.8 Hz, 1 (d, I = 8.4 Hz, 1 H); ¹³C NMR (CDCl₃, 75.5 MHz) δ 20.04, 20.15, 26.26, 25.30, 39.74, 30.21, 34.77, 38.60, 39.14, 44.13, 47.41, 55.24, 111.54, 113.53, 123.94, 126,21, 133.30, 138.05, 139.54, 157.48; exact mass, m/z calcd for $C_{20}H_{26}O$ 282.1984, found 282.1983. Anal. Calcd for C₂₀H₂₆O: C, 85.05; H, 9.28. Found: C, 84.99; H, 9.63.

Cis-5-[2-[[(1,1-Dimethylethyl)diphenylsilyl]oxy]ethyl]-2-cyclopenten-1-ol (20a).

(a) Cis-(3,3a,4,6a)-Tetrahydro-2H-cyclopenta[b]-furan-2-one. Sodium bicarbonate (66.4 g, 0.70 mol) and iodine (120.7 g, 0.47 mol) were added with vigorous stirring to a cooled (0 °C) solution of 2-cyclopentene-1-acetic acid (20.0 g, 0.158 mol) in 75% THF-water. The cold-bath was left in place and allowed to attain room temperature. After 16 h, the reaction mixture was diluted with ether (1000 mL) and washed with water (1 x 250 mL). The organic layer was washed with 10% aqueous sodium thiosulfate (1 x 200 mL), water, (1 x 200 mL), and brine (1 x 200 mL), and dried (MgSO₄). Evaporation of the solvent gave the desired iodo lactone (38.4 g) as a red-brown oil, which was used without further purification.

1,8-Diazabicyclo[5.4.0]undec-7-ene (27.8 mL, 0.185 mol) was added in one portion to a stirred solution of the crude iodo lactone (36.12 g, 0.143 mol) in dry benzene (650 mL). The mixture was stirred and refluxed for 4 h, cooled to room temperature, and filtered through a sintered glass funnel to remove insoluble salts. The filtrate was diluted with ether (1000 mL), washed with water (1 x 250 mL), and brine (1 x 250 mL), and dried (MgSO₄). Evaporation of the solvent gave crude *cis*-(3,3a,4,6a)-tetrahydro-2*H*-cyclopenta[b]furan-2-one (12.7 g, 71.3%). The combined aqueous layers were saturated with sodium chloride and continuously extracted with ether for 4 h. The ether was dried and evaporated to afford more product (7.2 g, 40.4%): ¹H NMR (CDCl₃, 80

- MHz) δ 1.90–3.40 (m, 7 H), 5.40 (d, J = 7.0 Hz, 1 H), 5.50–5.90 (m, 1 H), 5.90–6.20 (m, 1 H). The material was used directly in the next step.
- (b) Cis-5-(2-Hydroxyethyl)-2-cyclopenten-1-ol. The crude lactone from the previous step (10.0 g, 0.08 mol) was added over 5 min to a cold (0 °C) and stirred suspension of lithium aluminum hydride (6.11 g, 0.161 mol) in ether (300 mL). The cold-bath was removed and stirring was continued for 2 h. The mixture was then quenched by slow addition of saturated aqueous ammonium chloride (200 mL). The organic layer was separated, and the aqueous layer was saturated with sodium chloride and extracted continuously with ether for 16 h. The combined organic extracts were dried (MgSO₄) and evaporated to afford the required diol (10.0 g). Flash chromatography over silica gel (7 x 30 cm) using 50% ethyl acetate—hexane gave the pure diol (8.6 g, 86% based on 2-cyclopentene-1-acetic acid): 1 H NMR (CDCl₃, 80 MHz) δ 1.30-2.50 (m, 5 H), 3.0-3.95 (m, 4 H), 4.65 (broad s, 1 H), 5.75-6.15 (m, 2 H).
- (c) Cis-5-[2-[[(1,1-Dimethylethyl)diphenylsilyl]oxy]ethyl]-2-cyclopententert-3.43 mmol) and Imidazole (233 mg, 1-ol (20a). butylchlorodiphenylsilane 82 (440 μ L, 1.72 mmol) were added to a cold (0 °C) and stirred solution of the above diol (200 mg, 1.56 mmol) in dry DMF (3.2 mL). The cold-bath was left in place and allowed to attain room temperature. After 11 h, the mixture was quenched by addition of saturated aqueous ammonium chloride (5 mL), and diluted with ether (25 mL). The organic layer was washed with water (1 x 10 mL), and brine (1 x 10 mL), and dried (MgSO₄). Evaporation of the solvent and flash chromatography of the residue over silica gel (2.0 x 18.0 cm) using 15% ethyl acetate--hexane gave 20a (442 mg, 77%) as a thick, colorless oil: FT-IR (CHCl₃ cast) 3400, 2930, 2857, 1472, 1427, 1112, 1084, 701, 505 cm⁻¹; 1 H NMR (CDCl₃, 300 MHz) δ 1.06 (s, 9 H), 1.68 (ddd, J = 14.4, 9.5, 4.4 Hz, 1 H), 1.96-2.30 (m, 3 H), 2.38 (dddd, J = 15.6, 7.4, 2.8, 1.6

Hz, 1 H), 2.81 (d, J = 4.1 Hz, 1 H), 3.67 (dt, J = 9.7, 3.9 Hz, 1 H), 3.81 (m, 1 H), 4.73-4.81 (broad m, 1 H), 5.92 (m, 1 H), 6.01 (broad dt, J = 6.0, 2.2 Hz, 1 H), 7.32-7.49 (m, 6 H), 7.60-7.80 (m, 4 H); 13 C NMR (CDCl₃, 75.5 MHz) δ 19.05, 26.82, 31.58, 37.54, 41.63, 64.36, 76.32, 127.77, 129.79, 132.82, 133.08, 133.17, 135.29, 135.60; exact mass, m/z calcd for C₁₉H₂₁O₂Si [(M - C₄H₉)+] 309.1311, found 309.1311. Anal. Calcd for C₂₃H₃₀O₂Si: C, 75.36; H, 8.25. Found: C, 75.27; H, 8.39.

 $(1\alpha,2\beta,3\beta,5\alpha,6\alpha)$ - and $(1\alpha,2\beta,3\beta,5\alpha,6\beta)$ -3-[2-[[(1,1-Dimethylethyl)diphenylsilyl]oxy]ethyl]-6-methylbicyclo[3.1.0]hexan-2-ol (20b).#

The procedure is based on a general literature method.³³, Samarium metal (Research Chemicals, Phoenix, Arizona, *ca* 40 mesh, 1.15 g, 7.65 mmol) was flame dried in a 50-mL round-bottomed flask equipped with a Teflon-coated stirring bar and purged with a stream of argon. The flask was allowed to cool to room temperature and dry THF (18 mL) was added, followed by a solution of mercuric chloride in THF (1.5 M, 407 μL, 0.6 mmol). Stirring was continued for 10 min at room temperature and then allylic alcohol 20a (650 mg, 1.77 mmol) in dry THF (2 mL) was introduced via a cannula over about 10 min. The mixture was cooled to -78 °C and 1,1-diiodoethane (2.0 g, 7.08 mmol) was injected dropwise over about 5 min. The cold-bath was left in

[#] The samarium-mediated cycloprapanation proceeds with syn direction by the hydroxyl (reference 33). The stereochemistry at C(6) was not determined.

place and allowed to attain room temperature. After 8 h, the mixture was diluted with dichloromethane (20 mL) and quenched with saturated aqueous ammonium chloride (15 mL). Stirring was continued for 3 min, and the aqueous layer was separated and extracted with dichloromethane (1 x 25 mL). The combined organic extracts were washed with water (1 x 15 mL), and brine (1 x 15 mL), and dried (MgSO₄). Evaporation of the solvent and flash chromatography of the residue over silica gel (3 x 20 cm) with 15% ethyl acetate--hexane afforded 20b (313 mg, 45%; 69% based on conversion) and recovered starting material 20a (230 mg). Compound 20b had: FT-IR (CHCl₃ cast) 3460, 2929, 2858, 1595, 1428, 1112, 701 cm⁻¹; 1 H NMR (CDCl₃, 300 MHz) $^{\delta}$ 1.0 (s, 3 H), 1.0--1.1 (m, including a singlet at 1.05, 11 H), 1.17--1.27 (m, 1 H), 1.32 (ddd, J = 14.3, 9.5, 4.5 Hz, 1 H), 1.42 (m, 1 H), 1.88 (m, 1 H), 2.06 (ddd, J = 13.0, 9.2, 6.3 Hz, 1 H), 2.21 (m, 1 H), 2.70 (broad s, 1 H), 3.54 (dt, J = 10.0, 4.0 Hz, 1 H), 3.67 (dt, J = 10.0, 4.0 Hz, 1 H), 4.63 (broad t, J = 6.5 Hz, 1 H), 3.67 (dt, J = 10.0, 4.0 Hz, 1 Hz)H), 7.35--7.48 (m, 6 H), 7.63--7.71 (m, 4 H); 13 C NMR (CDCl₃, 75.5 MHz) δ 18.08, 19.02, 19.57, 26.83, 26.92, 32.35, 34.61, 35.49, 48.77, 64.66, 73.95, 127.75, 129.75, 133.10, 133.20, 135.58, 135.63; exact mass, m/z calcd for $C_{21}H_{25}O_2Si$ [(M - C_4H_9)+] 337.1624, found 337.1622. Anal. Calcd for C₂₅H₃₄O₂Si: C, 76.09; H, 8.68. Found: C, 75.77; H, 8.58.

(1,1-Dimethylethyl)[2-[6-methyl-2-(phenylseleno)-bicyclo[3.1.0]hex-3-yl]ethoxy]diphenylsilane (20c).#

[#] Stereochemistry at C(2) and C(6) was not determined.

Phenylselenocyanate (137 mg, 0.75 mmol) in dry THF (0.5 mL) was added dropwise over about 5 min to a stirred solution of cyclopropyl alcohol 20b (197 mg, 0.5 mmol) and tributylphosphine (187 μ L, 0.75 mmol) in dry THF (5 mL). Stirring at room temperature was continued for 4 h. Evaporation of the solvent and flash chromatography of the residue over silica gel (2 x 20 cm) using 20% dichloromethane--hexane (to remove diphenyl diselenide) followed by 5% ethyl acetate--hexane gave the selenide 20c as a single isomer (154 mg, 58 %) and an olefinic byproduct (48 mg, 26 %). Selenide 20c had: FT-IR (CHCl₃ cast) 2929, 1580, 1111, 701 cm⁻¹; 1 H NMR (CDCl₃, 200 MHz) δ 0.52 (d of septets, J = 6.0, 3.2 Hz, 1 H), 0.91 (d, J = 6.0 Hz, 3 H), 1.02 (s, 9 H), 1.06--1.50 (m, 5 H), 1.52 (m, 1 H), 2.14 (ddd, J = 13.0, 9.7, 5.5 Hz, 1 H), 2.33 (m, 1 H), 3.27 (d, J = 3.8 Hz, 1 H), 3.48 (t, J = 8.0 Hz, 1 H), 7.15 (m, 3 H), 7.30 - 7.45 (m, 6 H), 7.45 - 7.45 (m, 6 H)7.57(m, 2 H), 7.60--7.70 (m, 4 H); 13 C NMR (CDCl₃, 75.5 MHz) δ 17.76, 19.19, 23.00, 26.93, 28.72, 33.74, 34.70, 40.77, 45.69, 50.67, 62.75, 126.95, 127.66, 128.94, 129.60, 131.10, 133.72, 133.97, 135.64; exact mass, m/z calcd for C₃₁H₃₈OSeSi 534.1857, found 534.1855. Anal. Calcd for C₃₁H₃₈OSeSi: C, 69.77; H, 7.18. Found: C, 69.61; H, 7.34.

Cis-(1,1-Dimethylethyl)[2-(4-ethyl-2-cyclopenten-1-yl)ethoxy]diphenylsilane (20d).

The general photochemical method for radical ring opening was followed using selenide 20c (107 mg, 0.2 mmol) in dry hexane (3 mL) and tributyltin hydride (81 μ L, 0.3 mmol). The mixture was stirred and irradiated at 0-10 °C for 45 min, and then at 10-30 °C for 1.5 h. At this stage, some starting material still remained (TLC, silica, 5% ethyl acetate--hexane). Tributyltin hydride (25 μ L) was added and the mixture was stirred and irradiated for 40 min at 10-30 °C. Evaporation of the solvent and flash chromatography of the residue over silica gel (1.5 x 20 cm) using 1% ethyl acetate--hexane afforded 20d (52 mg 69%) as a slightly yellow oil:# FT-IR (CHCl3 cast) 2957, 2930, 2857, 1582, 1472, 1428, 1112, 702 cm⁻¹; 1 H NMR (CDCl₃, 300 MHz) δ 0.9 (t, J = 7.5 Hz, 3.6 H), 1.07 (s, 9 H), 1.18--1.60 (m, 3.4 H), 1.75 (dq, J = 13.5, 7.0 Hz, 1 H), 2.18 (dt, J = 12.7, 8.0 Hz, 1 H), 2.52 (m, 1 H), 2.75 (m, 1 H), 3.71 (t, J = 6.9 Hz, 1 H), 5.62 (m, 2 H), 7.32--7.45 (m, 6 H), 7.62--7.73 (m, 4 H); 13 C NMR (CDCl₃, 75.5 MHz) δ 12.31, 19.25, 26.95, 29.54, 37.04, 39.79, 42.41, 47.52, 62.96, 127.64, 129.54, 134.16, 134.69, 135.64; exact mass, m/z calcd for $C_{21}H_{25}OSi$ [(M - C_4H_9)+] 321.1675, found 321.1678. Anal. Calcd for C₂₅H₃₄OSi: C, 79.30; H, 9.05. Found: C, 79.39; H, 9.03.

Ethyl [1R-(1 α ,2 α ,4 β ,5 α ,6 α ,7 α)]-5-(Benzoyloxy)-4-(bromomethyl)-2-methoxy-3-oxabicyclo[4.1.0]-heptane-7-carboxylate (21c).

[#] The 1 H NMR spectrum (200 MHz) showed a byproduct (ca 6mol% of the total). The corrected yield is 65%.

The procedure is based on a general literature method.⁵² Barium carbonate (533 mg, 2.7 mmol) and then N-bromosuccinimide (freshly recrystallised from water; 354 mg, 1.99 mmol) were each added in one portion to a hot (50 °C) solution of sugar 21b# (596 mg, 1.8 mmol) in dry carbon tetrachloride (32 mL) contained in a 100-mL round-bottomed flask equipped with a condenser. The oil bath temperature was then raised to 90 °C and the mixture was allowed to reflux for 2 h. The hot solution was filtered through a sintered glass funnel and the insoluble material was washed with hot carbon tetrachloride (4 x 5 mL). The combined filtrates were evaporated and the residue was diluted with ethyl acetate (100 mL). The solution was washed with water (2 x 10 mL), dried (MgSO₄), and evaporated. chromatography of the residue over silica gel (2 x 20 cm) using 15% ethyl acetate--hexane afforded 21c (611 mg, 82%) as a white solid: FT-IR (CHCl3 cast) 1723, 1285, 712 cm⁻¹; 1 H NMR (CDCl₃, 300 MHz) δ 1.26 (t, J = 7.0 Hz, 3 H), 1.8 (m, 2 H), 1.93 (dd, J = 5.0, 9.9 Hz, 1 H), 3.37 (dd, J = 11.3, 7.5 Hz, 1 H), 3.55 (s) and 3.56 (dd, J = 11.5, 2.5 Hz) [both signals together correspond to 4 H], 4.0--4.2 [m, including quartets at 4.13 (J = 7.0 Hz) and at 4.14 (J = 7.0 Hz), 3 H], 4.96 (s, 1 H), 5.07 (d, J = 9.2 Hz, 1 H), 7.47 (m, 2 H), 7.62 (m, 1 H), 8.07 (m, 2 H); 13 C NMR (CDCl₃, 75.5 MHz) δ 14.18. 21.97, 23.09, 24.45, 32.68, 55.68, 61.07, 66.79, 67.13, 96.84, 128.56, 129.32, 129.85, 133.60, 165.55, 171.89; exact mass, m/z calcd for C₁₈H₂₁O₆Br 414.0501, found 414.0526. Anal. Calcd for C₁₈H₂₁BrO₆: C, 52.31; H, 5.12; O, 23.23; Br,19.34. Found: C, 52.04; H, 5.26; O, 23.18; Br, 20.08.

 $[\]mbox{\# Synthesized}$ in four steps from $\alpha\mbox{-Methyl}$ glucoside (reference 37 and 83).

Ethyl [2S- $(2\alpha,3\beta,6\beta)$]-6-(Bromomethyl)-3,6-dihydro-2-methoxy-2H-pyran-3-acetate (21d).

The procedure is based on a general literature method.⁵⁶ Magnesium perchlorate hexahydrate (152 mg, 0.46 mmol) in water (1 mL), and water (7 mL) were added to a solution of N-methylcarbazole (87 mg, 0.482 mmol) and 21c (181 mg, 0.438 mmol) in distilled THF (80 mL). The mixture was then distributed among four 50-mL test tubes [using distilled THF (3 mL) as a rinse for each tube]. The tubes were capped with septa, flushed with argon and maintained under a static pressure of argon. The tubes were irradiated simultaneously for 10 h at room temperature using a Hanovia 200 W high pressure mercury lamp surrounded by a Pyrex filter. The reaction mixtures were then transferred to a 500-mL round-bottomed flask containing a mixture of saturated aqueous sodium bicarbonate (20 mL) and THF (50 mL). The resulting mixture was evaporated. The residue was extracted with ethyl acetate (2 x 75 mL), and the extracts were washed with saturated aqueous sodium bicarbonate (1 x 40 mL), and 50% brine-water (1 x 40 mL), and dried (MgSO₄). Evaporation of the solvent and flash chromatography of the residue over silica gel (2 x 20 cm) using 10% ethyl acetate--hexane afforded 21d (110 mg, 86%) as a colorless oil: FT-IR (CHCl₃ cast) 1733, 1370, 1265, 1170, 1120, 1040, 935, 730 cm⁻¹; 1 H NMR (CDCl₃, 300 MHz) δ 1.26 (t, J = 7.2 Hz, 3 H), 2.37--2.64 (m, 3 H), 3.44 (dd, J = 10.8, 5.5 Hz), 3.50 (s), 3.51 (dd, J = 10.8, 4.5 Hz) [the signals at 3.44, 3.50 and 3.51 together correspond to 5 H], 4.16 (q, J = 7.2 Hz, 2 H), 4.43 (m, 1 H), 5.71 (broad d, J = 10.0 Hz, 1 H), 5.89 (dm, J = 10.0 Hz, 1 H); 13 C NMR (CDCl₃, 75.5 MHz) δ 14.19, 34.95, 35.42, 37.40, 55.67, 60.56, 61.02, 67.37, 100.55, 126.30, 127.39, 171.65; exact mass, m/z calcd for C₁₀H₁₄BrO₃ [(M - CH₃O)+] 263.0106, found 263.0085. Anal. Calcd for C₁₁H₁₇BrO₄: C, 45.06; H, 5.85; O, 21.83. Found; C, 45.27; H, 6.02; O, 21.87.

Methyl [2(R),4(R)]-2,3-Dideoxy-2,3-[1-(ethoxycarbonyl)ethylidene]-4,6-()-(phenylmethylene)- α -D-mannopyranoside (22a).

The literature procedure³⁸ was followed, but with some modifications. Sodium hydride (7.56 g, 60% suspension in oil, 0.189 mol) was added in several portions over a period of 15 min to a stirred solution of triethyl 2-phosphonopropionate (45.0 g, 0.189 mol) in dry triglyme (150 mL) contained in a 500 mL round-bottomed flask equipped with a condenser. Stirring was continued for 30 min at room temperature, and methyl 2,3-anhydro-4,6-()-(phenylmethylene)-α-D-allopyranoside 21a⁸³ (10.1 g, 0.0378 mol) was added in one portion. The flask was lowered into an oil bath preheated to 140 °C. Heating at 140 °C was continued for 4 days. The brown solution was allowed to cool to room temperature, and was poured into saturated aqueous ammonium chloride (100 mL). The mixture was extracted with ether (2 x 200 mL), and the combined organic extracts were washed with water (3 x 50 mL), and dried (MgSO₄). Evaporation of the solvent and flash chromatography of the residue (which was applied to the column dissolved in a minimum

amount of dichloromethane) over silica gel (6 x 20 cm) using 20% ethyl acetate--hexane afforded 22a (5.99 g, 45%) as a thick oil containing traces of impurities (TLC, silica, 20% ethyl acetate--hexane): FT-IR (CHCl₃ cast) 2977, 2937, 1721 cm⁻¹; ¹H NMR (CDCl₃, 200 MHz) δ 1.20 (t, J = 7.6 Hz, 3 H), 1.38 (s, 3 H), 1.79 (d, J = 11.6 Hz, 1 H), 2.12 (dd, J = 11.6, 2.5 Hz, 1 H), 3.42 (s, 3 H), 3.43--3.51 (m, 1 H), 3.64--3.78 (m, 2 H), 4.11 (q, J = 7.6 Hz, 2 H), 4.23--4.38 (m, 1 H), 4.65 (s, 1 H), 5.60 (s, 1 H), 7.35--7.44 (m, 3 H), 7.47--7.58 (m, 2 H); exact mass, m/z calcd for C₁₉H₂₄O₆ 348.1573, found 348.1556.

[1(R)-(1 α ,2 α ,4 β ,5 α ,6 α)]-5-(Benzoyloxy)-4-(bromomethyl)-2-methoxy-7,7-dimethyl-3-oxa-bicyclo[4.1.0]heptane (22c).

Barium carbonate (571 mg, 2.89 mmol) and then *N*-bromosuccinimide (freshly recrystallised from water, 377 mg, 2.12 mmol) were added to a hot (65 °C) and stirred solution of methyl 4,6-O-(phenylmethylene)-2,3-dideoxy-2,3-C-isopropylidene- α -D-mannopyranoside³⁸ (555 mg, 1.93 mmol) in carbon tetrachloride (34 mL). Stirring at 65 °C was continued for 1 h and the hot suspension was filtered through a Whatman filter paper (No. 1). The insoluble material was washed with hot carbon tetrachloride (10 mL) and the combined filtrates were evaporated. Flash chromatography of the residue over silica gel (4.0 x 20 cm) with 10% ethyl acetate--hexane afforded 22b (501 mg, 71%) as a thick, colorless oil: FT-IR (CHCl₃ cast) 2950, 1722, 1274, 1111, 1027 cm⁻¹; ¹H NMR (CDCl₃, 300 MHz) δ 0.87 (d, J = 9.1 Hz, 1 H), 1.04 (dd, J = 9.1, 1.9

Hz, 1 H), 1.10 (s, 3 H), 1.25 (s, 3 H), 3.52 (s, J = 11.1, 8.0 Hz, 1 H), 3.58 (dd, J = 11.1, 2.3 Hz, 1 H), 3.89--3.98 (m, 1 H), 4.79 (s, 1 H), 4.85 (dd, J = 8.0, 1.9 Hz, 1 H), 7.43--7.51 (m, 1 H), 7.57--7.63 (m, 1 H), 8.02--8.11 (m, 2 H); 13 C NMR (CDCl₃, 75.5 MHz) δ 14.42, 17.33, 23.31, 26.09, 27.77, 32.77, 55.18, 67.02, 67.26, 97.52, 128.54, 129.72, 129.80, 133.39, 165.58; exact mass, m/z calcd for C₁₇H₂₁BrO₄ 370.0603, found 370.0599. Anal. Calcd for C₁₇H₂₁BrO₄: C, 55.42; H, 5.75; O, 17.37. Found: C, 55.23; H, 5.72; O, 17.47.

[$2S(2\alpha,3\beta,6\beta)$]-6-(Bromomethyl)-3,6-dihydro-3-(1-methylethyl)-2-methoxy-2H-pyran (22d) and [$2S(2\alpha,3\beta,6\beta)$]-6-(bromomethyl)-3,6-dihydro-3-(1-methylethenyl)-2-methoxy-2H-pyran (22e).

Magnesium perchlorate hexahydrate (308 mg, 0.932 mmol) in water (2 mL) and water (7 mL) were added to a solution of N-methylcarbazole (169 mg, 0.932 mmol) and 22c in distilled THF (104 mL). The mixture was then distributed among among four 50-mL test tubes [using distilled THF (3 mL) as a rinse for each tube]. The tubes were capped with septa, flushed with argon and maintained under a static pressure of argon. The tubes were irradiated simultaneously for 7 h at 25 °C using a Hanovia 400 W high pressure mercury lamp surrounded by a Pyrex filter. The mixtures were then transferred to a 500-mL round-bottomed flask containing saturated aqueous sodium bicarbonate (50 mL) and the resulting mixture was evaporated. The residue was extracted with ether (2 x 75 mL) and the extracts were washed with water

(1 x 40 mL), dried (MgSO₄), and evaporated. [In this particular run the crude material was kept at -5 °C for 48 h]. Flash chromatography of the residue over silica gel (3 x 20 cm) using mixtures of 2%, 5%, and 40% ethyl acetate--hexane, afforded a 1:1 mixture [¹H NMR (300 MHz)] of 22d and 22e (140 mg, 67%) as a colorless oil, as well as unidentified material (29 mg). The mixture of 22d and 22e had: FT-IR (CHCl₃ cast) 2959, 1192, 1117, 1048, 973, 961 cm⁻¹; 1 H NMR (CDCl₃, 300 MHz) δ 0.95 (t, J = 7.3 Hz, 3 H), 1.71--1.87 (m, 2.5 H), 1.87--2.03 (m, 1 H), 3.39--3.53 (m, including two singlets at 3.46 and 3.48, 5 H), 4.32--4.44 (m, 1 H), 4.715 (s, 0.5 H), 4.735 (s, 0.5 H), 5.70--5.89 (m, 2 H); 13 C NMR (CDCl₃, 75.5 MHz) δ 19.67, 20.53, 21.49, 30.74, 34.71, 34.97, 45.10, 46.95, 55.19, 55.40, 66.87, 67.12, 100.45, 100.48, 113.96, 125.95, 126.02, 126.88, 127.08, 143.74; mass for C₁₀H₁₇8¹BrO and C₁₀H₁₅8¹BrO (chemical ionization, NH₃) 268 (M + 18)+.

(R)-4,6,Di-O-acetyl-2,3-dideoxy-2,3-[(ethoxycarbonyl)methylene]- α -D-mannopyranosyl bromide and (R)-4,6,Di-O-acetyl-2,3-dideoxy-2,3-[(ethoxycarbonyl)methylene]- β -D-mannopyranosyl bromide (23c).

(a) Methyl (R)-2,3-Dideoxy-2,3-[(ethoxycarbonyl)-methylene]- α -D-mannopyranoside. A stirred suspension of 5% palladium on carbon (0.5 g) in glacial acetic acid (8 mL) was saturated with hydrogen and 21b³⁷ (1.01 g, 3.04 mmol) was added in one portion. Stirring under 1 atmosphere of hydrogen was continued for 17 h. The catalyst was then removed by filtration through a pad of Celite and the pad was washed with ethyl acetate (5 x 5 mL). The

combined filtrates were evaporated and traces of acetic acid were removed by azeotropic evaporation with toluene (15 mL). This evaporation was repeated twice more to afford a white solid which was used without further purification.

- (b) Methyl (R)-4,6-Di-O-acetyl-2,3-Dideoxy-2,3-{(ethoxycarbonyl)methylene]-\alpha-D-mannopyranoside. Acetic anhydride (0.75 mL, 9.12 mmol) and then 4-(dimethylamino)pyridine (37 mg, 0.3 mmol) were added, each in one portion, to a cold (0 °C) and stirred solution of the above diol (736 mg, 3.04 mmol) in dry pyridine. Stirring was continued for 4 h at room temperature. The mixture was diluted with dichloromethane (70 mL) and washed with aqueous hydrochloric acid 1 M (2 x 25 mL), saturated aqueous sodium bicarbonate (1 \times 20 mL), water (1 \times 20 mL), and brine (1 \times 20 mL), and dried (MgSO₄). Evaporation of the solvent and flash chromatography of the residue over silica gel (3 x 20 cm) using 30% ethyl acetate--hexane followed by azeotropic evaporation of the new residue with toluene (2 x 15 mL), for removal of traces of pyridine, afforded the required diacetate (881 mg, 88% from the diol) as a white solid: FT-IR (CHCl₃ cast) 3050, 1741, 1728, 1448 cm⁻¹; ¹H NMR (CDCl₃, 300 MHz) δ 1.27 (t, J = 7.2 Hz, 3 H), 1.69 (t, J = 5.0 Hz, 1 H), 1.72-1.82 [m, including a triplet at 1.78 (J = 5.0 Hz), 2 H], 2.09 (s, 3 H), 2.11 (s, 3H), 3.41 (s, 3 H), 3.86 (ddd, J = 9.4, 5.8, 3.1 Hz, 1 H), 4.03--4.20 (m, 4 H), 4.83 (d, J = 9.6 Hz, 1 H), 4.89 (s, 1 H); 13 C NMR (CDCl₃, 75.5 MHz) δ 14.15, 20.74, 20.95, 21.94, 22.94, 24.39, 55.09, 60.99, 63.29, 64.10, 64.84, 96.47, 169.92, 170.62, 171.92; exact mass, m/z for $C_{14}H_{19}O_7$ [(M - CH₃0)+] 299.1131, found 299.1133. Anal. Calcd for C₁₅H₂₂0₈: C, 54.54; H, 6.71. Found: C, 54.66; H, 6.60.
- (c) Methyl (R)-1,4,6-Tri-O-acetyl-2,3-dideoxy-2,3-[(ethoxycarbonyl)-methylene]- α -D-mannopyranose and Methyl (R)-1,4,6-Tri-O-acetyl-2,3-dideoxy-2,3-[(ethoxycarbonyl)methylene]- β -D-mannopyranose. A solution of

sulfuric acid (15 μ L) in acetic anhydride (1 mL) was injected over 5 min into a cold (0 °C) and stirred solution of the above mannopyranoside (438 mg, 1.34 mmol) in acetic anhydride (4 mL). Stirring was continued for 4 h at 0 °C. The mixture was diluted with dichloromethane (20 mL) and stirred for 10 min with saturated aqueous sodium bicarbonate (10 mL). The aqueous layer was extracted with dichloromethane (1 x 20 mL) and the combined organic extracts were washed with saturated aqueous sodium bicarbonate (1 x 10 mL), and water (1 x 10 mL), and dried (MgSO₄). Evaporation of the solvent and flash chromatography of the residue over silica gel (1.5 \times 20 cm) using 40% ethyl acetate--hexane afforded a mixture of the required triacetates in a ratio of 8:1 [1H NMR (200 MHz)] (469 mg, 99%) as a colorless oil: FT-IR (CHCl₃ cast) 1746, 1226 cm $^{-1}$; ¹H NMR (CDCl₃, 200 MHz) δ 1.32 and 1.33 (two superimposed triplets, J = 7.2 Hz, 3 H), 1.72--1.91 (m, 3 H), 2.10 (s), 2.17 (s), 2.185 (s) and 2.11 (s), 2.16 (s), 2.18 (s) [signals at 2.10, 2.11, 2.16, 2.17, 2.18 and 2.185 together correspond to 6 H], 3.7 (m, 0.11 H), 3.94 (ddd, J = 9.7, 5.1, 3.1 Hz, 1 H), 4.03--4.23 [m, including a quartet at 4.15 (J = 7.2 Hz), 4 H], 4.89 (d, J = 9.2 Hz, 1 H) 6.19 (d, J = 2.2 Hz, 0.11 H), 6.28 (s, 0.89 H); 13 C NMR (CDCl₃, 75.5 MHz) (signals due to major isomer only) δ 14.10, 20.64, 20.88, 20.99, 21.72, 21.95, 24.19, 61.19, 62.85, 63.69, 89.36, 169.20, 169.74, 170.59, 171.46; exact mass, m/z calcd for $C_{16}H_{22}O_{9}$ 358.1241, found 358.1277. Anal. Calcd for C₁₆H₂₂O₉: C,53.62; H, 6.12. Found: C, 53.88; H, 6.27.

(d) (R)-4,6,Di-O-acetyl-2,3-dideoxy-2,3-[(ethoxycarbonyl)methylene]- α -D-mannopyranosyl bromide and (R)-4,6,Di-O-acetyl-2,3-dideoxy-2,3-[(ethoxycarbonyl)methylene]- β -D-mannopyranosyl bromide (23c). Trimethylsilyl bromide (37 μ L, 0.28 mmol) was injected into a stirred solution of the above triacetates (51 mg, 0.14 mmol) in dry benzene (1.4 mL) contained in a 10-mL round-bottomed flask equipped with a condenser.⁵¹ The mixture was

lowered into a bath preheated at 65 °C and stirring was continued for an arbitrary period of 8 h. The mixture was cooled and evaporated (oil pump vacuum) to give the crude bromides 23c which were used without purification for the next step. The bromides are rather unstable, and, therefore, were kept under argon and protected from moisture.

4,6-Di-O-acetyl-1,5-anhydro-2,3-dideoxy-3-(2-ethoxy-2-oxoethyl)-D-arabino-hex-1-enitol (23d).

The general procedure for thermal radical ring opening was followed using the crude bromides 23c (about 0.143 mmol) in dry benzene (1.4 mL), tributyltin hydride (94 μ L, 0.35 mmol), and AIBN (2 mg, 0.012 mmol). Refluxing was continued for 2 h, and the mixture was cooled and evaporated. Flash chromatography (twice) of the residue over silica gel (1 x 15 cm) using 25% ethyl acetate--hexane afforded 23d [34.0 mg, 79% based on the anomeric acetates (see part c above)]: FT-IR (CHCl₃ cast) 2980, 1744, 1651, 1374, 1237, 1062, 1039 cm⁻¹; 1 H NMR (CDCl₃, 300 MHz) δ 1.26 (t, J = 7.2 Hz, 3 H), 2.09 (s, 6 H), 2.21 (dd, J = 16.0, 9.5 Hz, 1 H), 2.49 (dd, J = 16.0, 5.0 Hz, 1 H), 2.88 (m, 1 H), 3.99 (dd, J = 16.0, 5.0 Hz, 1 H), 2.88 (m, 1 H), 3.99 (dd, J = 16.0, 5.0 Hz, 1 H), 2.88 (m, 1 H), 3.99 (dd, J = 16.0, 5.0 Hz, 1 H), 2.88 (m, 1 H), 3.99 (dd, J = 16.0, 5.0 Hz, 1 H), 2.88 (m, 1 H), 3.99 (dd, J = 16.0, 5.0 Hz, 1 H), 2.88 (m, 1 H), 3.99 (dd, J = 16.0, 5.0 Hz, 1 H), 3.99 (dd, J = 16.0, 5.0 Hz, 1 H), 3.99 (dd, J = 16.0, 5.0 Hz, 1 H), 3.99 (dd, J = 16.0, 5.0 Hz, 1 H), 3.99 (dd, J = 16.0, 5.0 Hz, 1 H), 3.99 (dd, J = 16.0, 5.0 Hz, 1 H), 3.99 (dd, J = 16.0, 5.0 Hz, 1 H), 3.99 (dd, J = 16.0, 5.0 Hz, 1 H), 3.99 (dd, J = 16.0, 5.0 Hz, 1 H), 3.99 (dd, J = 16.0, 5.0 Hz, 1 H), 3.99 (dd, J = 16.0, 5.0 Hz, 1 H), 3.99 (dd, J = 16.0, 5.0 Hz, 1.0 Hz,(ddd, J = 10.0, 5.0, 2.4 Hz,1 H), 4.14 (q, J = 7.2 Hz) and 4.17 (d, J = 12.3 Hz) [both signals together correspond to 3 H], 4.36 (dd, J = 12.3, 5.0 Hz, 1 H), 4.68 (dd, J = 12.3) 6.0, 2.0 Hz, 1 H), 4.97 (t, J = 9.4 Hz, 1 H), 6.38 (dd, J = 6.0, 2.1 Hz, 1 H); 13 C NMR $(CDCl_3, 75.5 \text{ MHz}) \delta 14.21, 20.76, 20.85, 35.32, 37.29, 60.63, 62.12, 68.83, 74.86,$ 102.14, 143.06, 170.09, 170.76, 171.68; exact mass, m/z calcd for $C_{12}H_{17}O_5$ [(M -C₂H₃O₂)+] 255.0869, found 255.0865; mass (chemical ionization, NH₃) 318 [(M + 18)+]. Anal. Calcd for C₁₄H₂₀O₇: C, 55.99; H, 6.71. Found: C, 55.78; H, 6.86.

Ethyl (±)-Bicyclo[4.1.0]hept-3-ene-7-carboxylate (37).58

Treatment of 1,4-cyclohexadiene (12.40 g, 0.154 mol) with ethyl diazoacetate (8.8 g, 0.08 mol) in the presence of rhodium(II) acetate (66 mg) at room temperature according to a literature procedure,⁵⁸ afforded 37 (8.9 g, 70%) as a mixture of stereoisomers with an endo:exo ratio of 3:7: bp 78-79 °C (*ca.* 5 mm); ¹H NMR (CDCl₃, 200 MHz) δ 1.19--1.32 [m, including triplets (J = 7.6 Hz) at δ 1.23 and δ 1.28, 3.3 H], 1.40--1.51 (m, 0.6 H), 1.62--1.77 (m, 2.3 H), 2.20--2.56 (m, 4 H), 4.09 (q, J = 7.6 Hz) and 4.13 (q, J = 7.6 Hz) [both signals together correspond to 2 H], 5.48 (broad s, 1.4 H), 5.57 (broad s, 0.6 H).

Ethyl (±)-3-Acetoxy-4-(phenylseleno)bicyclo[4.1.0]heptane-7-carboxylate (38).

Diphenyl diselenide (8.4 g, 26.9 mmol) was added over 1 min to a solution of bromine (4.2 g, 25.2 mmol) in glacial acetic acid (80 mL). The mixture was stirred at room temperature for 10 min, and 37 (7.75 g, 46.7 mmol), followed by anhydrous potassium acetate (9.16 g, 93.4 mmol), were added successively, each in one portion⁶¹. After being stirred at room temperature for 2 h, the mixture was diluted with ether (500 mL), washed with water (1 x 200 mL), saturated aqueous sodium bicarbonate (1 x 100 mL), and water (1 x 100 mL), dried (MgSO₄) and evaporated. Flash chromatography

of the residue over silica gel (7 x 24 cm) using successively 5%, 8%, and 15% ethyl acetate--hexane afforded 38 (11.56 g, 65%) as a slightly yellow oil that was a mixture of isomers. The major component [ca 85 mol%, AcO and C(7) syn] had: 1 H NMR (CDCl₃, 200 MHz) δ 1.27 (t, J = 7.3 Hz, 3 H), 1.50--2.66 (m, including a singlet at δ 1.97, 1 H), 3.72--3.79 (dm, J = 10.0 Hz, 1 H), 4.11 (q, J = 7.3 Hz, 2 H), 4.79-4.94 (m, 1 H), 7.20--7.33 (m, 3 H), 7.46--7.63 (m, 2 H).

Ethyl (±)-3-Acetoxybicyclo[4.1.0]hept-4-ene-7-carboxylate (39).

Pyridine (4.69 mL, 58 mmol) and then 30% w/w aqueous hydrogen peroxide (6.67 mL, 58 mmol) [addition over 15 min (see the caution in reference 84)] were added to a stirred solution of 38 (from the previous experiment, 11.01 g, 29 mmol) in dichloromethane (130 mL). Stirring was continued for 15 min after the addition of the hydrogen peroxide, and THF (20 mL) was then added in order to obtain an homogeneous mixture. After a further 2 h (stirring), the mixture was diluted with ether (300 mL), washed with 10% w/v aqueous sodium thiosulfate (1 x 100 mL), and water (1 x 100 mL), dried (MgSO₄) and evaporated. Flash chromatography of the residue over silica gel (5 x 17 cm) using 15% ethyl acetate--hexane afforded 39 (6.05 g, 93%) as an oil. The material was largely (85 mol%; ¹H NMR) a single isomer of the indicated stereochemistry and had: ¹H NMR (CDCl₃, 300 MHz) (major signals only) δ 1.29 (t, J = 7.2 Hz, 3 H), 1.81 (broad t, J = 4.2 Hz, 1 H), 1.92--2.07 (m, including a singlet at δ 2.04, 1 H), 2.20 (dm, J = 16.0 Hz, 1 H), 4.08--4.21 (m, 2 H), 5.27--5.34 (m, 1 H), 5.73 (dd, J = 10.0, 5.7 Hz, 1 H), 6.32--6.39 (m, 1 H); ¹³C

NMR (CDCl₃, 75.5 MHz) δ 14.22, 20.96, 21.22, 22.16, 24.68, 31.66, 60.54, 65.56, 122.65, 132.60, 170.37, 172.51; exact mass, m/z calcd for C₁₂H₁₇O₄ 225.1127, found 225.1125.

Ethyl $(1\alpha,3\beta,6\alpha,7\alpha)$ - (\pm) -3-Hydroxybicyclo[4.1.0]hept-4-ene-7-carboxylate (34).

Sodium hydride (60% dispersion in oil, 203 mg, 5.08 mmol) was added in several portions over 2 min to a stirred solution of 39 (5.72 g, 25.4 mmol) in anhydrous ethanol. After being stirred at room temperature for 2 h, the mixture was quenched with saturated aqueous ammonium chloride (20 mL) and concentrated (water-pump vacuum) to ca. 40 mL. The concentrate was diluted with ether (400 mL), washed with water (2 x 50 mL), dried (MgSO₄) and evaporated. Flash chromatography of the residue over silica gel (5 x 21 cm) using 20% ethyl acetate--hexane afforded the allylic alcohol 34 (3.66 g, 79%) as a slightly yellow oil: FT-IR (CHCl₃ cast) 3456 (broad), 2981, 2909, 1723, 1702, 1641, 1193 cm⁻¹; ¹H NMR (CDCl₃, 300 MHz) δ 1.26 (t, J = 7.0 Hz, 3 H), 1.85--2.01 (m, 4 H), 2.07 (broad d, J = 15.2 Hz, 1 H), 2.51 (broad s, 1 H), 4.12 (q, J = 7.0 Hz, 2 H), 4.26--4.32 (m, 1 H), 5.76 (dd, J = 9.8, 5.2 Hz, 1 H), 6.23 (dd, J = 9.8, 3.8 Hz, 1 H); ¹³C NMR (CDCl₃, 75.5 MHz) δ 14.14, 21.45, 22.58, 27.29, 32.66, 60.45, 62.52, 127.32, 130.09, 173.06; exact mass, m/z calcd for C₁₀H₁₄O₃ 182.0943, found 182.0942. Anal. Cald for C₁₀H₁₄O₃: C, 65.91; H, 7.74. Found: C, 65.29; H, 7.63.

5-Methoxy-2-propionylbenzenol (41).

A solution of 1,3-dimethoxybenzene (70.8 g, 0.51 mol) and propionyl chloride (42.23 mL, 0.486 mol) in dry benzene (500 mL) was added dropwise with stirring over 30 min to aluminum trichloride (74 g, 0.56 mol) and the mixture was kept at 25 °C by a water bath.63 After being stirred at room temperature for 1 h, and then at reflux for 2 h, the mixture was allowed to cool to room temperature and was then carefully treated with cold (0 °C) 1 M aqueous hydrochloric acid (500 mL). The organic layer was separated, dried (MgSO₄) and evaporated. Recrystallisation of the residue from 95% ethanol afforded 41 (46.5 g, 47%): FT-IR (CHCl₃ cast) 3800--1700, 1631, 1612, 1371, 1206, 1131 cm⁻¹; ¹H NMR (CDCl₃, 300 MHz) δ 1.12 (t, J = 7.4 Hz, 3 H), 2.94 (q, J = 7.4 Hz, 2 H), 3.82 (s, 3 H), 6.38--6.42 (m) and 6.44 (d, J = 2.9 Hz) [both signals together correspond to 2 H], 7.64 (dm, J = 9.5 Hz, 1 H), 12.84 (s, 1 H); ¹³C NMR (CDCl₃, 75.5 MHz) δ 8.42, 31.09, 55.45, 100.93, 107.40, 113.29, 131.28, 165.21, 165.81, 205.29; exact mass, m/z calcd for C₁₀H₁₂O₃ 180.0787, found 180.0791. Anal. Cald for C₁₀H₁₂O₃: C, 66.67; H, 6.67. Found: C, 66.74; H, 6.73

5-Methoxy-2-propylbenzenol (42).

Mercuric chloride (10 g) was added in several portions over 5 min to a suspension of powdered zinc (100 g) in 9 M aqueous hydrochloric acid (75 mL).64 The phenol 41 (24.9 g) was added in one portion and the mixture was refluxed for 1.5 h, allowed to cool to room temperature, and carefully diluted with 5 M aqueous sodium hydroxide (50 mL). The residue was extracted continuously for 5 h with ethyl acetate, and the solution was dried (MgSO₄) and evaporated. The resulting blue oil was distilled to afford pure 42 (20.34 g, 88%) as a colorless oil which slowly solidified to white crystals: (bp 115--118 $^{\circ}$ C, 0.34 mm); FT-IR (CHCl₃ cast) 3405, 2940, 1620, 1593, 1519, 1161, 1123 cm⁻¹; ¹H NMR (CDCl₃, 300 MHz) δ 0.95 (t, J = 7.2 Hz, 3 H), 1.60 (sextet, J = 7.2 Hz, 2 H), 2.50 (broad t, J = 7.2 Hz, 2 H), 3.64 (s, 3H), 5.20 (s, 1 H), 6.36 (d, J = 2.4 Hz, 1 H), 6.44 (dd, J = 9.0, 2.4 Hz, 1 H), 7.0 (d, J = 9.0 Hz, 1 H); 13 C NMR (CDCl₃, 75.5 MHz) δ 13.92, 23.14, 31.31, 55.34, 101.73, 105.95, 120.84, 130.63, 154.27, 158.76; exact mass, m/z calcd for C₁₀H₁₄O₂ 166.0994, found 166.0992. Anal. Cald for C₁₀H₁₄O₂: C, 72.26; H, 8.49. Found: C, 72.57; H, 8.60.

4-Chloro-5-methoxy-2-propylbenzenol (43).

A solution of freshly distilled sulfuryl chloride (5.58 mL, 69.42 mmol) in dry ether (20 mL) was added dropwise over 15 min (syringe pump) to a stirred solution of 42 (11.9 g, 66.1 mmol) in the same solvent (60 mL).⁶⁵ After 30 min, more sulfuryl chloride (1.1 mL, 13.68 mmol) in dry ether (5 mL) was added over 3 min and stirring was continued for 1 h. The mixture was then

concentrated (water-pump), diluted with ether (200 mL) and water (200 mL), and stirred for 40 min. The organic layer was separated and washed with water (1 x 100 mL), dried (MgSO₄) and evaporated. Flash chromatography (twice) of the brown residue over silica gel (7 x 12 cm) using 10% ethyl acetate-hexane afforded 43 (9.88 g, 70%) as a yellow oil which becomes black within hours at room temperature but which remains pure for at least 3 days at room temperature as judged by ¹H NMR and combustion analysis measurements: FT-IR (CHCl₃ cast) 3450, 2960, 1511, 1205, 1149 cm⁻¹; ¹H NMR (CDCl₃, 300 MHz) δ 0.94 (t, J = 7.2 Hz, 3 H), 1.59 (sextet, J = 7.2 Hz, 2 H), 2.47 (t, J = 7.2 Hz, 2 H), 3.78 (s, 3 H), 5.23 (broad s, 1 H), 6.41 (s, 1 H), 7.07 (s, 1 H); ¹³C NMR (CDCl₃, 75.5 MHz) δ 13.79, 22.91, 31.01, 56.22, 100.79, 113.36, 121.35, 130.84, 152.85, 153.55; exact mass, m/z calcd for C₁₀H₁₃³⁵ClO and C₁₀H₁₃³⁷ClO, 200.0604 and 202.0575, found 200.0618 and 202.0591. Anal. Cald for C₁₀H₁₃ClO: C, 59.85; H, 6.53. Found: C, 59.66; H, 6.50.

2-Bromo-4-chloro-3-methoxy-6-propylbenzenol (44).

Bromine (7.29 g, 45.53 mmol) in glacial acetic acid (25 mL) was added dropwise over 15 min (syringe pump) to a stirred solution of 43 (7.29 g, 33.8 mmol) in the same solvent (70 mL). After 45 min, the solvent was evaporated and the residue was diluted with ether (250 mL), washed with water (2 x 100 mL), dried (MgSO₄) and evaporated. Flash chromatography of the resulting red oil over silica gel (70 x 180 mm) using 5% ethyl acetate--

hexane afforded 44 (9.2 g, 92%) as a reddish transparent oil that was 90 mol% pure [¹H NMR, (300 MHz)]: FT-IR (CHCl₃ cast) 3507, 2960, 1477, 1431, 1398, 1157 cm⁻¹; ¹H NMR (CDCl₃, 300 MHz) (major signals only) δ 0.94 (t, J = 7.2 Hz, 3 H), 1.60 (sextet, J = 7.2 Hz, 2 H), 2.59 (t, J = 7.2 Hz, 2 H), 3.86 (s, 3 H), 5.58 (s, 1 H), 7.09 (s, 1 H); ¹³C NMR (CDCl₃, 75.5 MHz) δ 13.86, 22.61, 32.31, 60.64, 106.87, 119.03, 126.56, 129.73, 149.94, 151.01; mass for C₁₀H₁₂⁷⁹Br³⁵ClO₂, C₁₀H₁₂⁷⁹Br³⁷ClO₂ and C₁₀H₁₂⁸¹Br³⁷ClO₂ (chemical ionization, NH₃) 296 (M + 18)+, 298 (M' + 18)+ and 300 (M'' + 18)+. Anal. Cald for C₁₀H₁₂BrClO₂: C, 42.96; H, 4.33; O, 11.45. Found: C, 42.44; H, 4.25; O, 11.30.

2-Bromo-6-chloro-3-[dimethyl(1,1-dimethylethyl)silyl]oxy-4-propylbenzenol (45).

tert-Butylchlorodimethylsilane (2.67 g, 17.7 mmol) was added in one portion to a stirred solution of 44 (90 mol% pure, 5.0 g, 18.0 mmol) and imidazole (2.52 g, 37.1 mmol) in dry dimethylformamide (40 mL). After 1.5 h, the mixture was diluted with ether (350 mL) and washed with water (1 x 200 mL). The aqueous layer was extracted with ether (1 x 150 mL) and the combined organic layers were washed with water (1 x 200 mL), dried (MgSO₄) and evaporated. Filtration of the residue through silica gel (7 x 15 cm) using 6% ethyl acetate--hexane afforded impure silyl ether (6.5 g) which was used directly in the next step without further purification.

Boron tribromide (1 M in dichloromethane, 20.7 mL, 20.7 mmol) was added over 2 min to a cold (-78 °C) and stirred solution of crude silvl ether (6.5 g, 16.57 mmol) in dry dichloromethane (100 mL). Stirring at 0 °C was continued for 1.5 h, and the mixture was quenched with saturated aqueous sodium bicarbonate (100 mL) and diluted with ether (300 mL). The organic extracts were washed with water (100 mL), dried (MgSO₄) and evaporated. Flash chromatography of the residue over silica gel (7 x 18 cm) using 1% ethyl acetate--hexane afforded pure 45 (5.56, 82% from 44): FT-IR (CHCl₃ cast) 3507, 2958, 2930, 1468, 1424, 1191, 833, 782 cm⁻¹; ^1H NMR (CDCl₃, 300 MHz) δ 0.27 (s, 6 H), 0.91 (t, J = 7.2 Hz, 3 H), 1.03 (s, 9 H), 1.54 (sextet, J = 7.2 Hz, 2 H), 2.50 (t, J = 7.2 Hz, 2 H), 4.25--5.75 (broad, 1 H), 7.07 (s, 1 H); 13 C NMR (CDCl₃, 75.5 MHz) δ -2.44, 13.78, 18.92, 23.29, 26.20, 32.61, 104.69, 112.64, 127.26, 128.58, 147.24, 150.36; mass for $C_{15}H_{24}^{79}Br^{35}ClO_2Si$, $C_{15}H_{24}^{79}Br^{37}ClO_2Si$ and $C_{15}H_{24}^{81}Br^{37}ClO_2Si$ (chemical ionization, NH₃) 396 (M + 18)+, 398 (M' + 18)+, 400 (M" + 18)+. Anal. Cald for C₁₅H₂₄BrClO₂Si: C, 47.43; H, 6.37; Halogens (based on Cl), 18.66. Found: C, 47.19; H, 6.25; Halogens (based on Cl), 18.28.

Ethyl $(1\alpha,3\alpha,6\alpha,7\alpha)$ - (\pm) -3-(2-Bromo-6-chloro-3-hydroxy-4-propyl-phenoxy)bicyclo[4.1.0]hept-4-ene-7-carboxylate (46).

Diethyl azodicarboxylate (1.87 g, 1.69 mL, 10.7 mmol) was added over 2 min to a cold (-40 °C) and stirred solution of triphenylphosphine (2.83 g, 10.8 mmol) in dry THF (60 mL). After 30 min at -40 °C, the mixture became a thick

paste and was therefore allowed to attain room temperature (over 30 min), and then diluted with dry THF (30 mL). The suspension, which could now be stirred, was cooled to -30 °C and alcohol 34 (1.98 g, 10.9 mmol) in dry THF (7 mL + 2 mL rinse) was injected over 3 min by cannula. After being stirred at -30 °C for 1 h, and then at -20 °C for 1 h, phenol 45 (1.65 g, 4.35 mmol) in dry THF (5 mL + 2 mL rinse) was added over 2 min by cannula to the suspension. All the solids dissolved as soon as the addition was complete. The solution was stirred at -20 °C for 1 h and the solvents were then evaporated. Flash chromatography of the residue over silica gel (7 x 18 cm) using 4% ether-hexane afforded 46 (1.92 g). The material contained some impurities but was used directly in the next step: FT-IR (CHCl₃ cast) 29.58, 1726, 1458, 1180, 855 cm⁻¹; 1 H NMR (CDCl₃, 300 MHz) δ 0.28 (s, 6 H), 0.93 (t, J = 7.8 Hz, 3 H), 1.03 (s, 9 H), 1.24 (t, J = 7.2 Hz, 3 H), 1.49-1.61 (m, 3 H), 1.90-1.99 (m, 2 H), 2.03-2.15 (m, 1 H), 2.49--2.61 (m, 3 H), 4.11 (q, J = 7.1 Hz, 2 H), 4.55--4.64 (m, 1 H), 5.89 (broad d, J = 10.3 Hz, 1 H), 6.10 (dm, J = 10.3 Hz, 1 H), 7.09 (s, 1 H); ¹³C NMR (CDCl₃, 75.5 MHz) δ -2.35, 13.82, 14.25, 18.93, 19.30, 20.46, 23.04, 25.07, 26.21, 26.89, 32.80, 60.58, 75.58, 113.15, 120.84, 126.99, 127.61, 129.29, 131.19, 150.01, 150.75, 172.64; exact mass, for $C_{25}H_{36}^{79}Br^{35}ClO_4Si$ (chemical ionization, NH₃) 560 (M + 18)+. Anal. Cald for C₂₅H₃₆BrClO₄Si: C, 55.19; H, 6.67; Halogens (based on Cl), 13.04. Found: C, 55.25; H, 6.81; Halogens (based on Cl), 12.77.

The reaction is capricious; on a few occasions lower yields (30-70%) were obtained

Tetrabutylammonium fluoride (1 M in THF, 6 mL, 7.06 mmol) was added in one portion to a stirred solution of crude silyl ether of 46 (1.92 g, ca. 3.5 mmol) in dry THF (20 mL). After 1.5 h, the mixture was diluted with ether (200 mL), washed with water (2 x 50 mL), dried (MgSO₄) and evaporated. Flash chromatography (twice) of the residue over silica gel (4 x 19 cm) using

first 8% and then 10% ethyl acetate--hexane afforded pure 47 (1.19 g, 64% from phenol 45) as a colorless oil: 1 H NMR (CDCl₃, 200 MHz) δ 0.96 (t, J = 7.8 Hz, 3 H), 1.27 (t, J = 7.2 Hz, 3 H), 1.53--1.87 (m, 3 H), 1.97--2.02 (m, 2 H), 2.03--2.18 (m, 1 H), 2.55--2.70 (m, 3 H), 4.16 (q, J = 7.1 Hz, 2 H), 4.58--4.72 (m, 1 H), 5.65 (s, 1H), 5.89 (broad d, J = 10.3 Hz, 1 H), 6.15 (dm, J = 10.3 Hz, 1 H), 7.11 (s, 1 H).

In a previous run on ca. 1/10 scale, the yield from phenol 45 was 75%.

Ethyl $(3\alpha,4a\alpha,9b\alpha)$ - (\pm) -(6-chloro-9-hydroxy-8-propyl-3,4,4a,9b-tetra-hydrodibenzofuran-3-yl)acetate (48) and Ethyl (\pm) -[3-(6-chloro-3-hydroxy-4-propylphenoxy)cyclohexa-3,5-dienyl]acetate (49).

 $\stackrel{HO}{\longleftarrow}$ $\stackrel{HO}{\longleftarrow}$ $\stackrel{CO_2Et}{\longleftarrow}$ $\stackrel{CO_2Et}{\longleftarrow}$ $\stackrel{HO}{\longleftarrow}$ $\stackrel{HO}{\longleftarrow}$ $\stackrel{CO_2Et}{\longleftarrow}$ $\stackrel{CO_2Et}{\longleftarrow}$

Triethylborane (1 M in hexane, 0.17 mL, 0.17 mmol) and then tributyltin hydride (47 μ L, 0.17 mmol) were added to a solution of 47 (48 mg, 0.111 mmol) in dry benzene (distilled over CaH₂, 10 mL) and the mixture was stirred for 24 h. The solvent was evaporated and the residue was diluted with ether (3 mL) and stirred with an excess of potassium fluoride in water. After 1 h, the mixture was diluted with ether (10 mL) and the organic layer was washed with water (3 mL), dried (MgSO₄) and evaporated. Flash chromatography of the residue over silica gel (1.5 x 12 cm) using successively

10%, 15% and 20% ethyl acetate--hexane afforded 48 (17 mg, 43%) as a white solid and 49 (7 mg, 18%) as colorless oil. Compound 48 had: mp 124-130 °C; FT-IR (CHCl₃ cast) 3402, 2951, 1714, 1614, 1479, 1280, 1250, 1215, 1195, 1024 cm⁻¹; 1 H NMR (CDCl₃, 200 MHz) δ 1,0 (t, J = 7.5 Hz, 3 H), 1.30 (t, J = 7.2 Hz, 3 H), 1.42--1.75 (m, 3 H), 2.35--2.55 (m, 5 H), 2.80--3.0 (m, 1 H), 3.93--4.02 (m, 1 H), 4.19 (q, J = 7.2 Hz, 2 H), 4.71 (broad s, 1 H), 5.08--5.18 (m, 1 H), 5.76 (d, J = 10.2 Hz, 1 H), 5.88 (dt, J = 10.2, 3.2 Hz, 1 H), 6.86 (s, 1 H); [Irradiation at δ 5.8 caused the signal at δ 3.93--4.02 to collapse to a dd (J = 8.0 Hz, 1.2 Hz), the signal at δ 2.80--3.0 to simplify slightly. Irradiation at δ 3.98 caused the signal at δ 5.88 to collapse to a dd (J = 10.0, 3.2 Hz), the signal at δ 5.08--5.18 to collapse to a triplet (J = 3.6 Hz). Irradiation at δ 2.88 caused the signal at δ 1.42--1.75 to simplify, the signal at δ 2.35--2.55 to simplify, the signal at δ 3.93--4.2 to collapse to a dd (J = 7.6, 2.0 Hz), and the signal at δ 5.88 to collapse to a dd (J = 10.0, 3.2 Hz)]; ¹³C NMR (CDCl₃, 75.5 MHz) δ 13.82, 14.20, 23.13, 26.61, 31.13, 31.29, 39.87, 40.16, 60.65, 82.17, 106.31, 118.13, 122.14, 125.11, 129.15, 131.15, 149.10, 154.20, 172.54; exact mass, m/z calcd for C₁₉H₂₃ClO₄ (35Cl) 350.1285 and (37Cl) 352.1255, found (35Cl) 350.1286 and (37Cl) 352.1263. Anal. Cald for C₁₉H₂₃ClO₄: C, 65.04; H, 6.61; O, 18.24. Found: C, 64.88; H, 6.50; O, 17.97. Compound 49 had: ¹H NMR (CDCl₃, 200 MHz) δ 1.01 (t, J = 7.2 Hz, 3 H), 1.30 (t, J = 7.2 Hz, 3 H), 1.60--1.80 (m, 2 H), 2.34 (dd, J = 16.0, 8.0 Hz, 1 H), 2.45--2.59 (m) and 2.67 (ddd, J = 16.0, 7.6, 0.8 Hz) [both signals together correspond to 3 H], 2.92-3.12 (m, 1 H), 4.17 (q, J = 7.2 Hz, 2 H), 4.95 (d, J = 1 H), 5.14 (s, 1 H), 5.48 (dd, J = 8.8, 4.8 Hz, 1 H), 5.83 (ddd, J = 8.8, 4.8 Hz, 1 H)6.0, 1.6 Hz, 1 H), 6.58 (s, 1 H), 7.13 (s, 1 H).

The radical reaction is initiated by traces of oxygen in the solvent.⁵⁰ In a subsequent run, where benzene freshly distilled over sodiumbenzophenone ketyl, was used the reaction was sluggish and required a large excess of triethylborane and tin hydride.

$(3\alpha,4a\alpha,9b\alpha)$ - (\pm) -(6-Chloro-9-hydroxy-8-propyl-3,4,4a,9b-tetra-hydrodibenzofuran-3-yl)acetic acid (50)

Lithium hydroxide monohydrate (33 mg, 0.78 mmol) was added to a stirred solution of 48 (55 mg, 0.157 mmol) in 60% THF-water. After 8 h, the mixture was diluted with ether (6 mL) and water (6 mL). The aqueous layer was separated, acidified to pH 2 using 6 M aqueous hydrochloric acid and extracted with ether (2 x 6 mL). The organic extracts were dried (MgSO₄) and evaporated to yield the desired carboxylic acid 50 (50 mg, 100%) as a brownish solid: mp 176-181 °C; FT-IR (THF cast) 3700--2100, 2959, 1708, 1617, 1473, 1428, 1275, 1235, 1208 cm⁻¹; ¹H NMR (THF-d₈, 200 MHz) δ 0.95 (t, J = 7.1 Hz, 3 H), 1.48--1.68 (m, 3 H), 2.30 (d, J = 7.2 Hz, 2 H), 2.36--2.58 (m, 3 H), 2.68--2.88 (m, 1 H), 3.89--3.99 (m, 1 H), 4.97--5.07 (m, 1 H), 5.70 (d, J = 10.5 Hz, 1 H), 5.81 (dt, J = 10.5, 2.5 Hz, 1 H), 6.78 (s, 1 H), 7.15--8.6 (broad, 1 H); exact mass, m/z calcd for C₁₇H₁₉ClO₄ 322.0971, found 322.0962.

Ethyl (±)-(6-chloro-9-hydroxy-8-propyl-1,2,3,4-tetrahydrodibenzofuran-3-yl)acetate (51).

Rhodium chloride trihydrate (50 mg, 0.21 mmol) was added to a stirred solution of 48 (150 mg, 0.428 mmol) in 20% ethanol--benzene (6 mL) contained in a 10-mL round-bottomed flask equipped with a condenser⁶⁶. The flask was lowered into an oil bath preheated at 65 °C and the mixture was stirred at that temperature for 18 h, allowed to cool to room temperature and evaporated. Flash chromatography of the black residue over silica gel (1.5 x 12 cm) using 20% ethyl acetate--hexane afforded 51 (125 mg, 84%) as a white solid: mp 123-124 °C;FT-IR (CHCl₃ cast) 3499, 1717, 1474, 1195, 854 cm⁻¹; ¹H NMR (CDCl₃, 200 MHz) δ 1.01 (t, J = 7.4 Hz, 3 H), 1.32 (t, J = 7.0 Hz, 3 H), 1.68 [sextet (J = 7.5 Hz) superimposed on a multiplet, 3 H], 2.00--2.11 (m, 1 H), 2.40--2.60 (m) and 2.60 (t, J = 7.8 Hz) [both signals together correspond to 6 H], 2.80-- $3.10 \text{ (m, 3 H)}, 4.20 \text{ (q, J} = 7.0 \text{ Hz, 2H)}, 4.79 \text{ (s, 1 H)}, 6.95 \text{ (s, 1 H)}; ^{13}\text{C NMR (CDCl}_3,$ 75.5 MHz) δ 13.79, 14.20, 20.74, 23.37, 28.59, 29.14, 30.97, 31.14, 40.08, 60.51, 107.73, 112.02, 118.68, 121.94, 124.57, 145.74, 149.67, 152.20, 172.55; exact mass, m/z calcd for C₁₉H₂₃ClO₄ (35Cl) 350.1285 and (37Cl) 352.1255, found (35Cl) 350.1289 and (37Cl) 352.1267. Anal. Cald for C₁₉H₂₃ClO₄: C, 65.04; H, 6.61; O, 18.24. Found: C, 65.15; H, 6.54; O, 18.07.

(±)-(6-Chloro-9-hydroxy-8-propyl-1,2,3,4-tetrahydrodibenzofuran-3-yl)acetic acid (52).

Hydrolysis of 51 (55 mg), under identical conditions to those used for 48, afforded acid 52 (50 mg, 100%) as a solid: mp 205-207 °C; FT-IR (THF cast)

3700--2100 (including peak at 3486), 1685, 1474, 1344, 1280, 1184, 852 cm⁻¹; ¹H NMR (THF-d₈, 300 MHz) δ ¹ 0 (t, J = 7.6 Hz, 3 H), 1.50--1.78 (m, 3 H), 1.95--2.15 (m, 1 H), 2.30--2.60 (m, 4 H), 2.66 (t, J = 7.9 Hz, 2 H), 2.74--3.11 (m, 3 H), 6.92 (s, 1 H), 7.55 (br, 1 H); exact mass, m/z calcd for C₁₇H₁₉³⁵ClO₄ 322.0972, found 322.0968.

Ethyl $(1\alpha,3\alpha,6\alpha,7\alpha)$ - (\pm) -3-(2-Bromophenoxy)bicyclo[4.1.0]hept-4-ene-7-carboxylate (35).

Diethyl azodicarboxylate (0.21 mL, 1.32 mmol) was added over 2 min to a cold (-40 °C) and stirred solution of triphenylphosphine (0.35 g, 1.32 mmol) in dry THF (8 mL). After 30 min at -40 °C, the mixture became a thick paste and was therefore allowed to attain room temperature (over 30 min) and diluted with dry THF (5 mL). The suspension, which could now be stirred, was cooled to -40 °C and alcohol 34 (240 mg, 1.32 mmol) in dry THF (2 mL + 1 mL rinse) was injected over 3 min by cannula. After being stirred at -40 °C for 1 h, and then at -20 °C for 1 h, o-bromophenol (81 μL, 0.66 mmol) was injected over 2 min. All the solids dissolved as soon as the addition was complete. With the cold bath left in place, the mixture was allowed to attain room temperature (over ca. 1 h) and the solvents were then evaporated. Flash chromatography of the residue over silica gel (2 x 18 cm) using 12% etherhexane afforded crude 35 which was further purified using a Chromatotron [circular plate coated with a 2 mm-thick adsorbent (silica gel 60 PF₂₅₄ containing gypsum)]. Successive elution with 4%, 8%, and 12% ether-hexane

gave pure 35 (72 mg, 33%) as a colorless oil: FT-IR (CHCl₃ cast) 1720, 1475, 1183 cm⁻¹; ¹H NMR (CDCl₃, 300 MHz) δ 1.27 (t, J = 7.0 Hz, 3 H), 1.63 (t, J = 3.8 Hz, 1 H), 1.82--2.03 (m, 3 H), 2.55--2.70 (m, 1 H), 4.13 (q, J = 7.0 Hz, 2 H), 4.55--4.65 (m, 1 H), 5.72 (broad d, J = 10.2 Hz, 1 H), 6.18 (dm, J = 10.2 Hz, 1 H), 6.82--6.93 (m, 2 H), 7.20--7.30 (m, 1 H), 7.50--7.57 (m, 1 H); ¹³C NMR (CDCl₃, 75.5 MHz) δ 14.26, 19.09, 20.39, 24.60, 27.09, 60.71, 71.32, 113.63, 115.77, 122.58, 126.50, 127.94, 128.36, 133.68, 154.31, 172.52; exact mass, m/z calcd for C₁₆H₁₇⁷⁹BrO₃ 336.0362, found 336.0350. Anal. Cald for C₁₆H₁₇BrO₃: C, 56.98; H, 5.08; O, 14.23. Found: C, 56.84; H, 4.91; O, 14.28.

Ethyl $(3\alpha,4a\alpha,9b\alpha)$ - (\pm) -(3,4,4a,9b-Tetrahydrodibenzofuran-3-yl)acetate (36).

Triethylborane (1 M in hexane, 0.22 mL, 0.22 mmol) and then tributyltin hydride (0.231 mL, 0.878 mmol) were added to a stirred solution of 35 (140 mg, 0.439 mmol) in dry hexanes (18 mL). The mixture was stirred at 35 °C for 24 h. The solvent was then evaporated and the residue was diluted with ether (6 mL) and stirred with an excess of potassium fluoride in water. After 1 h, the mixture was diluted with ether (20 mL) and the organic layer was washed with water (6 mL), dried (MgSO₄) and evaporated. Flash chromatography of the residue over silica gel (1.5 x 12 cm) using 5--10% ethyl acetate--hexane afforded 36 (71 mg, 67 %) and an unidentified side product (12 mg). Compound 36 had: FT-IR (CHCl₃ cast) 2860, 1731, 1597, 1477, 1230 cm⁻¹; ¹H NMR (CDCl₃, 300 MHz) δ 1.28 (t, J = 7.2 Hz, 3 H), 1.58--1.78 (m, 2 H), 2.31-

2.41 (m, including a doublet at δ 2.35, (J = 7.2 Hz), 3 H), 2.72--2.92 (m, 1 H), 3.79 (broad d, 7.2 Hz, 1 H), 4.17 (q, J = 7.2 Hz, 2 H), 5.06 (m, 1 H), 5.72 (broad s, 2 H), 6.77--6.90 (m, 2 H), 7.05--7.12 (m, 2 H); ¹³C NMR (CDCl₃, 75.5 MHz) δ 14.30, 26.90, 31.49, 40.25, 41.06, 60.45, 80.70, 109.94, 120.58, 124.51, 127.19, 128.28, 130.78, 130.86, 159.37, 172.12; exact mass, m/z calcd for C₁₆H₁₈O₃ 258.1255, found 258.1252.

Ethyl $(1\alpha,3\beta,6\alpha,7\alpha)$ - (\pm) -3-[3,5-Dinitrobenzoyloxy]bicyclo[4.1.0]hept-4-ene-7-carboxylate.

Freshly recrystallized 3,5-dinitrobenzoyl chloride (140 mg, 0.61 mmol), and then a few crystals of 4-(dimethylamino)pyridine were added in one portion to a stirred solution of 34 (85 mg, 0.47 mmol) in dry pyridine (1 mL). Stirring at room temperature was continued for an arbitrary period of 6 h and the mixture was then evaporated under reduced pressure. The residue was diluted with dichloromethane (20 mL) and the solution was washed with cold 1N aqueous hydrochloric acid (2 x 5 mL), saturated aqueous sodium bicarbonate (1 x 5 mL), and water (1 x 5 mL), dried (MgSO₄), and evaporated. Flash chromatography of the residue over silica gel (1 x 18 cm) using 15% ethyl acetate—hexane afforded the dinitrobenzoate derivative of 34 (ca 150 mg) as a white solid. Recrystallization from dichloromethane—hexane gave colorless thin crystals: 1 H NMR (CDCl₃, 200 MHz) δ 1.32 (t, J = 7.8 Hz, 3 H), 1.95 (t, J = 3.8 Hz, 1 H), 2.10—2.26 (m, 3 H), 2.38—2.54 (m, 1 H), 4.16 (q, J = 7.8 Hz, 2 H), 5.61—5.72 (m, 1 H), 5.86 (dd, J = 10.0, 6.0 Hz, 1 H), 6.46—6.60 (dm, J = 10.0 Hz, 1 H), 9.04—9.12 (m, 2 H), 9.16—9.24 (m, 1 H).

CHAPTER 2

PRELIMINARY STUDIES ON THE SYNTHESIS OF CALICHEAMICINONE

I. INTRODUCTION

Over the past four years considerable efforts have been devoted to elucidation of the structures and mechanism of action of a series of novel naturally occurring compounds called calicheamicins¹ and esperamicins.²

The compounds, which have powerful biological properties, were isolated from *Micromonospora echinospora* ssp calichensis and cultures of *Actinomadura verrucospora*, respectively. They are prominent members of a growing class of antitumor agents characterized by the presence of an enediyne moiety. Other members of this class include the previously discovered neocarzinostatin,³ the very recently discovered dynemicin A,⁴ as well as similar (or identical compounds) identified as FR-900405, FR-900406⁵ and the veractamycins PD114,759 and PD115,208.⁶

These substances have attracted enormous attention because of their complex and unusual structures, which represent a substantial challenge for synthetic organic chemists, and also because of their strong potency against murine tumors. The compounds are among the most powerful antitumor agents known.

The mode of action is believed to involve Bergman rearrangement of the 1,5-diyne-3-ene into a diyl radical which attacks DNA.

A very large number of synthetic studies have been reported in this area, some of them being aimed at constructing the central core enedigne bicyclic system, while others involve the peripheral carbohydrate attachments. The requirements for triggering the Bergman rearrangement are also being explored. All of these subjects are surveyed in the following paragraphs with emphasis on studies related to the calicheamicins.

The structure of calicheamicin γ_l^l was recently elucidated, although the

structure consists of two major portions. The first is represented by four sugar units, two of them being linked by a unique N-O glycosidic bond, and a fully substituted iodothiobenzoate moiety. The aglycon portion is a bicyclo[7.3.1]tridec-9-ene-2,6-diyne with a methyl trisulfide attachment, and an α,β -unsaturated ketone substructure bearing a methoxycarbonylamino group on the α carbon.

(A) BIOLOGICAL ASPECTS

Calicheamicin γ_1^I is 4000 times more active than adriamycin against murine tumors and its optimal dose is 0.5 to 1.5 µg per kilogram of body weight.⁷ The drug can also cause chromosome aberrations in human lung fibroblasts and mutagenesis in *Escherichia Coli*.

The antimicrobial and antitumor properties of the calicheamicins (and esperamicins) follows from their capacity to cut single and double stranded DNA.⁸ Evidence has been accumulated that the effector species for DNA degradation *in vitro* is a benzene diyl arising from chemically induced Bergman bond reorganization of the 1,5-diyne-3-ene moiety (Scheme 1).^{8,#,##}

In vivo, this reorganization would be triggered by bioreductive activation of calicheamicin, resulting in conversion of the methyl trisulfide into a thiolate. The latter attacks the α,β -unsaturated ketone in a Michael fashion, resulting in saturation of the bridgehead double-bond, thus

[#] For studies that demonstrate for the first time the existence of an intermediate benzenediyl, see reference 9.

changing the hybridization at C-1 from sp² to sp³. This change in hybridization allows the two triple bonds to approach each other so that the ends of the enediyne [C-3 and C-7] are close enough for cyclization to take place so as to form a phenylene diradical (Bergman cycloaromatization).¹¹

This diradical is believed to be the active form of the drug. It is responsible for abstracting a hydrogen atom from the sugar phosphate backbone of DNA, producing single and double-strand DNA cleavage. In some instances, the drug identifies sites for DNA degradation with remarkable sequence specificity.¹²

In the presence of thiol cofactors,⁷ calicheamicin γ_1^1 at concentrations as low as 0.01 µg/mL (7 nM) causes double strand and single strand breaks in supercoiled ϕ X174 DNA. In the absence of thiol cofactors, only slight cutting was observed at 0.1 µg/mL. At 0.1 µg/mL, single strand ϕ X174 was unaffected by the drug, indicating the preference of calicheamicin γ_1^1 for double strand DNA.

Without exception, the preferred site of attack was the 5'C of a TCCT sequence and three nucleotides towards the 3' side of the 3'G in the complementary AGGA box.⁷ This asymmetric cleavage pattern to the 3' side on opposite strands indicates interaction of the drug with the minor groove of DNA. This hypothesis is reinforced by a competition experiment with retropsin (which is known to bind in the minor groove) that caused significant alteration of the calicheamicin γ_1 ¹ cleavage site. Further observations led to the proposal of a cleavage mechanism of the TCCT sites at 5'C (Equation 1).⁷

Whereas the aglycon is perceived as the "source of latent chemical radiation", the carbohydrate sector is seen to be the DNA recognition device, as shown by Zein et al.¹² According to these studies the carbohydrate portion

becomes attached to the DNA in such a way that the enediyne core is held in an appropriate position for specific double strand cleavage.

Binding models depicting the calicheamicin-DNA encounter were proposed by two independent groups^{8,12,13} and, although the nature of the binding, as well as the source of one of the two hydrogens abstracted by the diyl moiety, are different in each model, both models involve an association between DNA and the thiobenzoate as well as the carbohydrate moiety# by a combination of hydrophobic, electrostatic and hydrogen-bonding interactions.

According to Zein et al., 12 this association then guides the enediyne moiety into the duplex DNA groove at sites where the local helix characteristics (such as groove width and angles) are favorable for the insertion. The movement of the enediyne unit within the groove is then controlled by the carbohydrate-thiobenzoate tail of calicheamicin γ_1 molecule.

In the presence of thiols, the diradical species then forms in the groove at sites such as TCCT/AGGA, where the spatial orientations are optimal. The diradical abstracts both hydrogens it requires from the sugars (one on each strand) and this initiates DNA double-strand scission. The recognition is not entirely specific and, therefore, when and if the diradical forms in a site on the DNA that is too "wide" and where the hydrogens on the deoxyribose sugars are not accessible, then it abstracts hydrogens from only one strand (as in a mismatch) or from thiol/solvent (as in the case of an unfavored site).

[#] For NMR studies leading to the conclusion that the carbohydrate tail would be a good binder, see reference 14.

(B) REQUIREMENTS FOR TRIGGERING THE BERGMAN REARRANGEMENT

Inspired by the striking capacity of esperamicin/calicheamicin to induce DNA strand scission via a diradical species, researchers have initiated programs directed towards the design and evaluation of simple structures that might mimic¹⁵ the biological action of the natural drugs. Concomitantly, studies were undertaken in order to try to understand the factors controlling biradical formation.

In work aimed at defining those factors, Nicolaou *et al.*¹⁶ gathered information on cyclic conjugated enediynes related to calicheamicin. MM2 calculations on the model compounds, which were either already known or had to be synthesized, led to the conclusion that the distance between the two carbons of the acetylene units was the determining factor in controlling the ease with which the Bergman cyclization takes place. Indeed, in cases where the distance was > 3.35 Å the enediyne could be isolated and was stable at 25 °C, whereas in cases where the distance was < 3.20 Å the compounds were not isolated but were only claimed as transient intermediates, suffering spontaneous cyclization to benzenoid systems. Therefore, the crucial turning point from stability to spontaneous cyclization is in the range of 3.31--3.20 Å.

Alternatively, Magnus *et al.*¹⁷ proposed that the driving force controlling spontaneous cyclization is not the distance but the overall change in strain energy between enediyne and cycloaromatized adduct.

This conclusion is supported by computational evidence 18 and by quantitative experimental and theoretical data. Indeed, in the case of 1 where n=0 (Scheme 2), even though the separation (r) between C-2 and C-8 is 3.368 Å (vs 3.391 for n=1), which is in the range postulated for ambient cycloaromatization (< 3.35 Å), the compound is very resistant to closure. It undergoes cycloaromatization 650 times more slowly at 124 °C than its higher homologue 3. Moreover, the cycloaromatization rate of alcohol 2 (which is more strain-free than its parent ketone) is 216 times faster than that of the ketone and 0.33 times the rate for 3, with n=1.

Scheme 2. Reagents and conditions: (a) 1,4-cyclohexadiene, 124 °C; (b) 1,4-cyclohexadiene, 84 °C.

It will be noticed that cycloaromatization was performed by heating a solution of 1-3 in 1,4-cyclohexadiene. Under these conditions, the former are

converted into their corresponding benzenediyl derivatives which abstract two hydrogens from cyclohexadiene to produce 4-6.

Compound 1 was synthesized as outlined below (Scheme 3).19

Scheme 3. Reagents and conditions: (a) lithium acetylide ethylenediamine complex, dioxane, 74%; (b) (Z)-dichloroethylene, Pd(PPh₃)₄, CuI, BuNH₂, 89%; (c) tert-BuMe₂SiOTf, Et₃N, CH₂Cl₂, 70%; (d) methyl propargyl ether, Pd(PPh₃)₄, CuI, BuNH₂, 88%; (e) Me₂BBr, -35 °C, 99%; (f) tert-BuMe₂SiOTf, Et₃N, 94%; (g) Co₂(CO)₈, heptane, 90%; (h) TiCl₄ (3.0 equiv), DABCO (1.0 equiv), -43 °C to -35 °C, 50%; (i) l₂, PhH, 70%.

Treatment of cyclohexane-1,2-dione with sodium hydride and methoxymethyl chloride gave 7, which was exposed to lithium acetylide/ethylenediamine complex in dioxane to give 8. Palladium mediated coupling of 8 with (Z)-dichloroethylene led to the enyne 9, and this was converted into silyl ether 10. A second palladium-mediated coupling of 10, this time with methyl propargyl ether, introduced the missing acetylene moiety and gave 11. Conversion of the enolether 11 to the silyl enol ether 13 and protection of one acetylene [dicobalt octacarbonyl/heptane] gave dicobalt hexacarbonyl adduct 14 (80% from 11). Formation of the dicobalt hexacarbonyl is necessary in order to avoid premature Bergman cycloaromatization. Pettit-Nicholas reaction on 14 generated the bicyclic compound 15 (50%) as a crystalline material, and finally, decomplexation with iodine afforded the target 13-ketobicyclo[7.3.1]diyene 1 as a reasonably stable compound.#

As stated previously, in the biological aspects section (page 124), an intramolecular thiolate addition to C-9 changes the hybridization from sp² to sp³, and this in turn triggers the cycloaromatization. The fact that such a process could be triggered intermolecularly by addition of thiols to C-10 was demonstrated by Magnus on model 17 (Scheme 4).²¹

Treatment of 1 with potassium hexamethyldisylazide and silylation, gave the bridgehead enol ether 16 (89%). When 16 was treated with phenylselenyl chloride followed by hydrogen peroxide, the bridgehead enone 17 was isolated in 83% yield.

[#] For an example of a very similar synthesis of 1, followed by cycloaromatization in carbon tetrachloride to give a dichlorobenzene analog of 6, see reference 20.

Scheme 4. Reagents and conditions: (a) 1,4-cyclohexadiene, 84 °C; (b) KHMDS, TBDMSOT(, 89%; (c) PhSeCl; then H_2O_2 , 83%; (d) 1,4-cyclohexadiene, 4-chlorothiophenol, N-methylmorpholine, 110 °C, 50%.

Compound 17 is a stable compound relative to 1. It should be noted that the structures assigned to 16 and 17 do not violate Bredt's rule. Heating a mixture of 1 and 17 in 1,4-cyclohexadiene at 80 °C converted 1 into 6, but left 17 unchanged. However, heating 17 at 110 °C in 1,4-cyclohexadiene in the presence of 4-chlorothiophenol and N-methylmorpholine gave the aromatized adduct 18.

In another investigation, aimed at determining the types of transformation that can be carried out on this system, unexpected results involving selenium dioxide oxidation were obtained.²² On the basis of the Sharpless mechanism for allylic oxidation of alkenes using selenium dioxide, it was expected that **16** would give **16a** (Scheme 5).

SCHEME 5 OTBDMS OTBDMS TBDMSO TBDMSO, TBDMSO. 16a 16 1 b **OTBDMS** HO, **TBDMSO** TBDMSO TBDMSO. H 19 20 22

Scheme 5. Reagents and conditions: (a) KHMDS, TBDMSOTf, THF, -78 °C, 89%; (b) ScO₂ (1.1 equiv), dioxane, 25 °C, 3 h, 19 (53%) and 20 (14%); (c) SeO₂, 40–50 °C, 90 h, 22 (52%) plus recovered 19 (23%).

Silylation of ketone 1 with gave the desired enol ether 16 (90%) and, when 16 was exposed to SeO₂, the major isolated compound was not 16a but the hemiketal 19 (53%) along with 20 (14%).

A plausible explanation for the observed products is shown in Equation 2. Electrophilic substitution by selenium dioxide at the bridgehead (C-9) leads to a α -seleno derivative, which can close to the selenooxetane 21 and the

latter can collapse by elimination to give 19 and 20. Further exposure of 19 to selenium dioxide gave the crystalline diol 22 (52%) (Scheme 5).

(C) SYNTHESES RELATED TO CALICHEAMICINONE

In work towards the synthesis of the central core of calicheamicin γ_1^1 , Magnus *et al.* used a strategy that involved only slight modification of the route followed in the synthesis of model compounds. This modification requires the use of an aldol reaction to generate the bicyclic diynene core and introduce a hydroxyl group at C-8 (with the correct stereochemistry). This C-8 hydroxyl is present in calicheamicin but was absent in the previous models.²³

The synthesis of 32 (Scheme 6) was achieved utilizing a modification of the route reported by Kadow,²⁴ which, in turn, is an adaptation of the original sequence developed by Magnus.¹⁹ Basically, the modification involves constructing the whole enediyne unit before (as opposed to after) the coupling with ketone 26 is performed. Palladium coupling of eneyne 23 with acetylene carboxaldehyde diethyl acetal gave the enediyne 24 (68%). Removal of the trimethylsilyl group and treatment of the terminal acetylene with lithium bis(trimethylsilyl)amide generated the lithio derivative 25, which was quenched with ketone 26 to produce 27. The latter undergoes silyl migration, thereby providing 28 in good yield (70%).

31

Co(CO)

Hydrolysis of diethoxy acetal 28 then gave aldehyde 29, and the less sterically hindered triple bond was selectively protected as the dicobalthexacarbonyladduct 30. Treatment of 30 with $n\text{-Bu}_2BOTf/amine$ base resulted in an aldol reaction mediated by a boron enolate, and gave rise to the 12β hydroxybicyclo[7.3.1]diynene/dicobalt hexacarbonyl adduct 31. Deprotection of the triple bond proceeded smoothly (N-methylmorpholine N-oxide) to afford the isolable diynene 32.

A different approach leading to a calicheamicin deoxyaglycon model was reported by Kende et al.²⁵ The key step involves reaction of enediyne aldehyde 44 with lithium hexamethyldisylazide so as to bring about an intramolecular acetylide cyclization to epimeric carbinols 45a and 45b (Scheme 7).

Scheme 7. Reagents and conditions: (a) inverse addition of 44, LiN(TMS)₂, THF; 42% total yield (based on 30% recovered 44), 45a:45b::3:1; (b) 0.2 M HCl, aqueous acctone, 90%.

Hydrolysis of the known 3,5-dimethoxy-1,4-dihydroxybenzyl alcohol 33 (Scheme 8) gave the β-methoxyenone 34 (63%) and Swern oxidation transformed 34 into aldehyde 35. This was converted (carbon tetrabromide, triphenylphosphine) into dibromoolefin 36. At that stage, protection of the carbonyl group in 36 as its enolate, followed by addition of *n*-butyl lithium afforded, after work-up, the acetylene 37 (76%). Addition of vinylmagnesium bromide at 0 °C, and quenching with dilute hydrochloric acid gave the conjugated dienone 38 (91%). To stabilize subsequent intermediates, dienone 38 was converted to the ketal 39.

Scheme 8. Reagents and conditions: (a) Dowex 50W-X8, MeOH, 63%; (b) DMSO, (COCl)2; then Et₃N, CH₂Cl₂, -78 °C; (c) Ph₃P, CBr₄, CH₂Cl₂, 0 °C, 51% from 34; (d) LDA, 1 ½; then *n*-BuLi, 2 equiv, 2 h, THF, -78 °C, 76%; (e) CH₂CHMgBr; then 2 N HCl, THF, 0 °C, 91%; (f) PPTS, ethylene glycol, PhH, 80 °C, 61%; (g) OsO₄, NMMO; then NalO₄, aqueous acetone; (h) NaBH₄, MeOH, 61% from 39; (i) (Z)-1-chloro-4-trimethylsilyl-1-buten-3-yne, Pd(PPh₃)₄, CuI, *n*-BuNH₂, ether, 59%; (j) DMSO, (COCl)₂; then Et₃N, CH₂Cl₂, -78 °C; (k) *n*-Bu₄NF, THF, 60% from 42.

Then, catalytic osmylation, followed by periodate cleavage, produced aldehyde 40 which was reduced to carbinol 41 in 63% overall yield. At this point, Castro-Stephans coupling of the acetylene with (Z)-1-chloro-4-trimethylsilyl-1-buten-3-yne gave the silyl enediyne 42 (59%). This compound was then oxidized under Swern conditions to the aldehyde 43.

Finally, desilylation produced the key cyclization precursor, the enediyne aldehyde 44. Inverse addition of 44 to a dilute solution of lithium hexamethyldisilazide in THF, followed by aqueous work-up led to a 3:1 mixture of epimeric cyclized carbinols 45a and 45b [42% (based on 30% recovered 44)] (Scheme 7). Deketalization of the mixture gave the epimeric enones 46a and 46b.

The stereochemistry of the major epimer was studied by NOE experiments and shown to be 45a. On the basis that 45a did not exhibit long range coupling (> 1.0 Hz for $J_{5,8}$), whereas in both the esperamicins and calicheamicin $\gamma_1{}^I$ $J_{5,8}$ is 1.4--2.7 Hz, it was suggested that the C-8 stereochemistry originally assigned for calicheamicin $\gamma_1{}^I$ may require revision, and this revision was subsequently made.

A synthesis of a bicyclic core related to the calicheamicin/esperamicin aglycon, using as a key reaction, the skeletal rearrangement of a mesylate derived from a type II Diels-Alder cycloadduct, was reported by Schreiber et al. This report²⁶ solved a problem that had been found in an earlier study by the same group. In that work, the regiochemical outcome (meta vs ortho) of the type II Diels-Alder cycloaddition leading to the alleged bicyclic core of calicheamicin/esperamicins had been incorrectly assigned.

The initial report²⁷ suggested that **48** was produced from **47** (Scheme 9). This regiochemistry was in accord with the outcome of other type II Diels-Alder cycloadditions as well as the directing properties of the diene and dienophile substituents. However, in this case, it turned out that *meta* selectivity was favored over *ortho* and so the actual product **49** was not useful for the intended synthesis.

Schen 9. Reagents and conditions: (a) hydroquinone, PhH, 80 °C, 49:48::7:1, 75%.

A similar strategy, but one that made use of a carbonate substituent instead of an α,β -unsaturated ester as the diene, was devised in order to solve the problem (Scheme 10).

Aldehyde 50 was prepared by hydrolysis of the corresponding diethoxyacetal which, in turn, was obtained by palladium-catalyzed coupling of (Z)-1,2-dichloroethylene, first with thexyldimethylsilyl acetylene, and then

SCHEME 10

Scheme 10. Reagents and conditions: (a) (i). 51, n-BuLi, MgBr₂, -78 °C; then 50, 79%. (ii). n-Bu₄NF. (iii). *tert*-Bu₄Me₂SiOTf, Et₃N, 80%; (b) bromovinylene carbonate, Pd(CH₃CN)₂Cl₂, Cu₁, Et₃N, PhH, 49%; (c) Kishi's radical inhibitor, PhH, 120 °C, 40%; (d) (i). K₂CO₃, H₂O/MeOH, 83%. (ii). MsCl, 73%. (iii). DDQ, 91%; (e) Et₂AlCl (6 equiv), CH₂Cl₂, -78 °C, 2 h then -78 °C to -20 °C, 2 h, 65%.

with 3,3-diethoxy-1-propyne (60%). The whole process could be achieved without isolation of intermediates. The vinyl stannane 51 was prepared in three steps from 2-butyne-1,4-diol, and coupling of 50 with the vinyl lithium derivative of 51, followed by desilylation of the acetylene and silylation of the resulting hydroxyl produced 52 (80% overall).

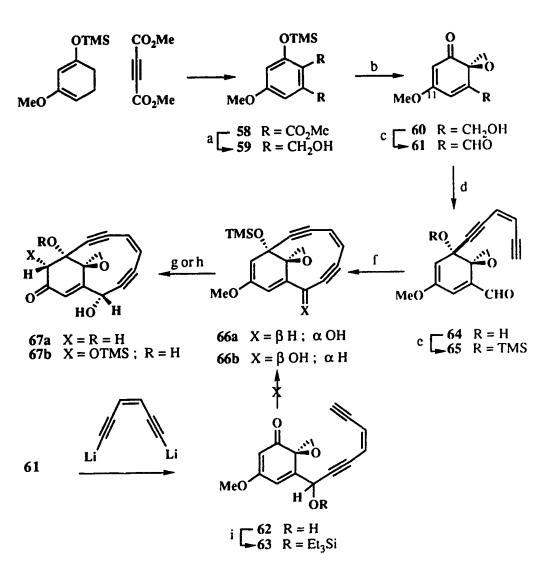

Palladium-mediated coupling of the terminal acetylene portion of 52 with bromovinylene carbonate then gave the cycloaddition precursor 53. When heated in the presence of Kishi's radical inhibitor, 53 underwent cycloaddition with excellent diastereoselectivity ($\beta/\alpha=20:1$) and the anticipated para bridged regioselectivity to provide 54. It will be noticed that in the process, the enediyne moiety, which is part of the calicheamicin molecule, has been used as a connector joining the diene and the dienophile and this connection provided a favorable geometric constraint, allowing the cyclization to take place easily.

Saponification of the cyclic carbonate 54, selective mesylation of the secondary hydroxyl, and removal of the *p*-methoxybenzyl protective group provided the pinacol substrate 55. Treatment of 55 with diethylaluminium chloride triggered a pinacol rearrangement which, after isomerization of the presumed intermediate 56, gave the desired enone 57.

Structure 57 now possess the correct skeleton of the bicyclic core of calicheamicin/esperamicin, but lacks only a hydroxyl group at C-1 (lost in the rearrangement process) and the urethane moiety at C-10.

Danishefsky et al. devised a strategy leading in a few steps to an extensively functionalised core. The central element of their approach is the coupling of ketoaldehyde 61 (Scheme 11) with the known (Z)-1,6-dilithiohexa-3-ene-1,5-diyne.

SCHEME 11

Scheme 11. Reagents and conditions: (a) LiAlH₄; (b) NaIO₄, aqueous THF, 65% overall; (c) Dess-Martin periodinane, 70%; (d) lithium N-methylanilide, THF, -40 °C; then 1,6-dilithio-hexa-3-ene-1,5-diyne (2 equiv), -78 °C, 60%; (e) TMSOTf, 70%; (f) KN(TMS)₂, PhMe, -78 °C, 52%, 66a:66b::10:1; (g) (CO₂H)₂, THF/H₂O, 90%; (h) m-CPBA, THF/H₂O, 50%; (i) TESOTf.

Compound 59 (Scheme 11), available by reduction of 58, was oxidized to 60 using sodium periodate, and reaction of 60 with the Dess-Martin periodinane then gave 61 (70%). At this point, introduction of the enediyne moiety is possible because the carbonyl group at C-11 is protected as methyl enol ether. Monoaddition of the dilithioenediyne to 61, and conversion of the resulting hydroxyl to its triethylsilyl derivative produced 63. Interestingly, 63 failed to undergo the desired cyclization to the triethylsilylether derivative of 66a. Success was achieved, however, by an adaptation of the Commins concept of in situ aldehyde protection. Treatment of the starting ketoaldehyde 61 with lithio N-methylanilide generated the lithio α -aminoalkoxide adduct, which was treated with 2 equiv of dilithioenediyne. This procedure gave, after work-up, the mono-adduct 64 (60%) resulting presumably by attack of the acetylide from the less hindered face of 61. Silylation of the alcohol and deprotonation of the terminal acetylene provided the bicyclic compounds 66a and 66b (10:1). Mild acidic hydrolysis or oxidation (m-CPBA/THF/water) of 66a gave 67a and 67b, respectively.

It will be noted that 67a represents a highly functionalised version of the calicheamicin core and that the siloxy ketone 67b contains the additional oxygen required for esperamicin, though an inversion at C-12 is still required. The spiro-epoxide moiety not only prevents the enone system from aromatizing but will also serve eventually as a handle for elaboration of the chain containing the trisulfide moiety.

In subsequent studies, attempts to deliver a range of nucleophiles to the bridgehead enone were unsuccessful and therefore, it became clear that in order to saturate the double bond and trigger the Bergman cycloaromatization, modification of the substrate would be necessary.²⁹

It was believed that this immunity against nucleophiles was due to steric hindrance by the pseudoaxial substituent at the one-carbon bridge and therefore the spiro-epoxide moiety had to be modified.

Solvolysis of 67a gave the tetrol 68 which was converted to enedione 69 (Scheme 12). Reaction of 69 with zinc in acetic acid reduced the double bond of the enedione system, thus giving 70, and thermolysis in the presence of 1,4-cyclohexadiene afforded the cycloadduct 71. Alternatively, treatment of 70 with sodium borohydride in the presence of 1,4-cyclohexadiene at room temperature gave cycloadduct 73. Here, reduction of the C-1 bridged ketone is thought to be the major factor responsible for accelerating the cycloaromatization. This interpretation is in keeping with discoveries of Magnus and co-workers in related model systems, where reduction of a ketone to an alcohol at the one-carbon bridge exerted the same effect. 19,30 Both 70 and 72 were shown to effect single and double strand cleavage of \$\phi X174 form I DNA.

As no intermolecular Michael reaction could be achieved on compound 67a, an alternative line of attack was sought which would study the feasibility of an intramolecular Michael addition. It was felt at the time that this alternative should work, at least in principle, since such a process is presumably involved in the natural product itself.³¹

Scheme 12. Reagents and conditions: (a) HCO₂NH₄, HCO₂H, THF/H₂O, 65 °C, 80%; (b) H₅IO₆, THF; (c) Zn, AcOH, 82% overall; (d) 1,4-cyclohexadiene, CH₃CN, 82 °C, 6 h, 40%; (e) NaBH₄, MeOH, 1,4-cyclohexadiene, 25 °C, 50%.

Careful solvolysis of the previously described spiro-epoxide 66a (Scheme 13) gave the enol ether 74 which was converted to dioxolane 75. Deacetylation and cleavage of the diol moiety with periodic acid afforded ketone 77 and then treatment with diethylphosphonylacetic acid and dicyclohexylcarbodiimide produced the monoester 78.

Scheme 13. Reagents and conditions: (a) AcOK, AcOH, DMSO, 50 °C; (b) dry ethylene glycol, CSA, 50 °C, 73% from 66a; (c) NH3, MeOH; (d) H51O6, THF, 76% from 75; (e) (EtO)₂P(O)CH₂CO₂H, DCC; (f) LiBr, Et₃N, THF, 67% from 77; (g) DIBAL-H, CH₂Cl₂, -78 °C then NaBH₄, MeOH/H₂O, 64%; (h) CSA, 1,4-cyclohexadiene, aqueous THF, 58%.

This compound underwent intramolecular Emmons condensation to lactone 79. It will be noticed that this process introduced the remaining two carbons needed to complete the skeleton and that the hydroxyl group that was esterified served to direct the Emmons condensation. In this way, the double bond at the one-carbon bridge is formed with the correct geometry. Reduction of the lactone moiety of 79 was achieved using diisobutylaluminium hydride followed by sodium borohydride to yield triol 80.

Treatment of 80 with camphorsulfonic acid in the presence of 1,4-cyclohexadiene gave the dihydrofuran 82 in 58% yield. Presumably, the ketal had cleaved and the resulting enone had then undergone in situ Michael addition by the proximal allylic alcohol. The sequence produced 81, which spontaneously cycloaromatizes. This example clearly shows that a properly placed intramolecular nucleophile is indeed capable of undergoing Michael addition to the enone, and thus triggering the Bergman cyclization.

Finally, Danishefsky *et al.* reported the attainment of the first and only total synthesis of the aglycon portion of calicheamicin in which, as they mention, "a solution [was found] to the problem of the elusive urethane".³²

The approach was similar to that used earlier on model systems by the same group. However, it was necessary to introduce the urethane function at the bridgehead double bond, and the optimal timing for this installation emerged as a serious problem. Commercially available ester 83 (Scheme 14) underwent regiospecific bromination to 84, which, upon formylation, gave 85.

SCHEME 14 OH OMe СНО b d MeO CO₂Me CO₂Me MeO MeO Вr Вr 87 — 83 R = H — 84 R = Br P = Mc= Hc MeO Br OH TMSO сно` MeO - 90 P = H - 91 P = TMS -- 88 X = H , OH -- 89 X = O 92 Br Br OH OH 1 НО -93 X = α OH; β CH₂OAc -94 X = α OH; β CH₂OH95

Scheme 14. Reagents and conditions: (a) NBS, CH₃CN; (b) Cl₂CHOMe, TiCl₄; (c) BCl₃; 63% from 83; (d) DIBAL-H; (e) NaIO₄; (f) Dess-Martin periodinane; *ca* 40% from 86; (g) lithium *N*-methylanilide then dilithioenediyne; (h) TMSOTf; (i) potassium 3-ethyl-3-pentoxide, 40% from 89; (j) (i)CSA, ethylene glycol, 89%. (ii) AcOK, AcOH, DMSO; (k) NH₃, MeOH; (l) NaIO₄; 83% overall.

The aldehyde function was employed to direct regiospecific monodemethylation (by boron trichloride), giving rise to the required phenol 86 (65% from 83). The sodium salt of 86 was reduced (diisobutylaluminium hydride) to provide an unstable triol 87, which, upon treatment with sodium periodate, afforded 88. Oxidation of crude 88 with the Dess-Martin periodinane led to the spiroaldehyde 89 (40% from 86).

The usual dilithioenediyne was added to the ketone (in the nominal presence of the aldehyde, using the in situ protection described previously) to give 90. Silylation of the tertiary alcohol and cyclization then provided the core system 92 (as a single isomer). Compound 92 was converted to the ketal 93. Acetolysis of the epoxide, deacetylation and cleavage of the diol moiety gave the ketone-ketal 95 (83% from 93). At this point, the bridgehead enone is set up for introduction of an azido function. For this to be possible, the ketone at the one-carbon bridge had to provide adequate enolate stabilization to support an addition-elimination mechanism, a possibility presaged by the research of Magnus.22,32, Reaction of 95 with sodium azide in methanol afforded 96 (82%). This last step not only introduces the crucial amine moiety necessary for elaboration to the target molecule but provides a very adequate protected form (azide) of the amine (Scheme 15). The alcohol was acylated and the resultant ester 97 subjected to intramolecular Emmons condensation. This operation produced the unsaturated lactone 98 (50% from 96). The conjugation afforded by the unsaturated lactone provided a sufficiently stable setting for the steps required to transform the azide to the methyl carbamate function.

Scheme 15. Reagents and conditions: (a) NaN3, MeOH, 82%; (b) (EtO)₂P(O)CH₂COCl, pyridine; (c) LiBr, Et₃N, THF, 50% f: Jm 96; (d) H₂S, piperidine, MeOH, 95%; (e) (COCl)₂, pyridine; (f) MeOH, pyridine, 80% overall; (g) DIBAL-H then NaBH₄, 43%; (h) CH₃COSH, Ph₃P, DIAD, 45%; (i) DIBAL-H; (j) phtalimidomethyl disulfide, 65% from 103; (k) CSA, aqueous THF, 65%.

Reduction of 98 (hydrogen sulfide-piperidine-methanol; 95%) led to the fairly robust vinylamine 99. This compound, upon treatment with phosgene in pyridine, produced the bis acylation product 100, and thence, upon treatment with methanol in pyridine, to the carbamate-carbonate 101 in 80% overall yield. Treatment of 101 with diisobutylaluminium hydride followed by sodium borohydride, gave the alcohol 102 (43%). The first sulfur atom was

introduced by a Mitsunobu reaction on 102 to produce 103. Deacetylation of 103 and treatment of the crude product with phthalimidomethyl disulfide gave the trisulfide 104 (65% from 103). Finally the ketal linkage was cleaved and there was obtained dl-calicheamicinone 105 as a powder in 65% yield.

When calicheamicinone 105 was treated with benzenethiol, triethylamine and 1,4-cyclohexadiene in methano! for 2 h at room temperatureit was converted into the cycloaromatized tetracycle 107 in 16% yield (Scheme 16).34 Similarly, 106 afforded 108 in 50% yield.

Scheme 16. : Sugents and conditions: (a) BnSH, Et₃N, 1,4-cyclohexadiene, MeOH, 50% 108 from 106, 16% 107 from 105.

In summary, the above work represents the first synthesis of calicheamicinone, the clean introduction of the trisulfide trigger, and the thiol-induced cleavage in these systems to initiate the cascade culminating in Bergman cycloaromatization. The urethane functionality is not crucial for the activation cascade, and the thiol used to initiate the cleavage represents a model for the possible involvment of glutathione.

(D) SYNTHESES RELATED TO THE SUGAR PORTION OF CALICHEAMICIN γI^{I}

Even though the main synthetic goal of many organic chemists has been focused on the bicyclic core of calicheamicin, the oligosaccharide fragment of the drug is also being pursued. So far, Nicolaou et al. reported the total synthesis of the whole fragment, and the synthesis of three of the five subfragments has been disclosed by Scharf et al. The approach disclosed by Scharf et al. will be discussed first.

The synthesis of the aromatic ring (ring C) was achieved in six steps (41%) from readily available methyl 4-O-benzylorsellinate 109.35 Compound 109 was selectively formylated at the 3 position to 110, and oxidized to phenol 111 by treatment with hydrogen peroxide in alkaline solution (Scheme 17). Methylation gave 112 and the benzyl group was removed by hydrogenolysis. Mild iodination with iodine chloride then yielded 114, and this compound was demethylated by alkaline hydrolysis to the desired product 115.

The sulfur containing fragment (ring B) was obtained by a radical-induced rearrangement of a 3,4-thionocarbonate derivative. Methyl 2,6-dideoxy- α -D-ribohexopyranoside 116 was esterified with thiocarbonyldiimidazole and the resulting thiocarbonate 117 was treated with tributyltin hydride and AIBN. The rearranged regioisomeric thiol carbonates 118 and 119 were formed in 31% and 41% yield, respectively (Scheme 18). Alkaline hydrolysis of 118 gave the desired thio sugar 120 as its methyl glycoside.

Scheme 17. Reagents and conditions: (a) Cl₂CHOMe, TiCl₄, 74%; (b) H₂O₂, aqueous NaOH; 90%; (c) Me₂SO₄, K₂CO₃, acetone; 81%; (d) H₂, Pd, 97%; (e) ICl, CH₂Cl₂, 90%; (f) alkaline hydrolysis.

SCHEME 18

Scheme 18. Reagents and conditions: (a) thiocarbonyldiimidazole (1.2 equiv), PhCH3, 60 °C, 81%; (b) Bu₃SnH (0.5 equiv), AlBN (1.2 equiv), PhH, 80 °C, 31% of 118 and 41% of 6; (c) alkaline hydrolysis; 75%.

Coupling of the two subunits (ring B and C) was achieved as follows.³⁷ Compound 114 was protected as its benzyl ether and the ester was converted to the acid chloride 123 (Scheme 19). Reaction of the thiosugar 120 with 123 in pyridine led to 124 (subunit BC) as a crystalline solid (59%).

SCHEME 19

Scheme 19. Reagents and conditions: (a) 1.1 equiv of PhCH₂Br, K₂CO₃, acetone, reflux, 92%; (b) 3 equiv of 5 N NaOH, DMSO, 100 °C, 81%, (c) 1.2 equiv of 1-chloro-N,N,2-trimethyl-1-propenyl-1-amine, CH₂Cl₂, 0–25 °C, 95%; (d) 120, pyridine, 2 d, 0–25 °C, 59%.

Subunit CD was prepared by coupling of phenol 114 (ring C) with the glycosyl bromide derivative 128 (ring D). Methyl glycoside 125 was treated with pivaloyl chloride to yield 126 (Scheme 20). The pivaloyl residue guarantees the 1,2 trans glycosidic coupling and diminishes the formation of by-products in the glycosylation step. Acetolysis gave 127, which was converted to the glycosyl bromide 128 using hydrogen bromide in acetic acid.

Coupling of 128 with phenol 114, using silver carbonate on Celite as a catalyst, gave rise to 129 and, finally, cleavage of the ester groups afforded 130 (subunit CD) as a colorless crystalline solid.

This work represents a synthesis of the subunits BC and CD of the olisaccharide fragment of calicheamicin $\gamma_1{}^{\rm I}$.

Scheme 20. Reagents and conditions: (a) PivCl, pyridine, 96%; (b) AcOH, Ac₂O, H₂SO₄ (32/32/1, v/v/v), 98%; (c) HBr, AcOH, CH₂Cl₂, 0–25 °C, 94%; (d) Ag₂CO₃ on Celite, PhCH₃, 50 °C, 41%; (e) MeONa, MeOH, 3 d, 52%.

The stereocontroled synthesis of the oligossacharide of calicheamicin γ_1^{I} as its methyl glycoside 131, reported by Nicolaou *et al.*, is based on a novel [3,3]-sigmatropic rearrangement that established the essential elements of ring B and delivered the target molecule in enantiomerically pure form and high overall yield.³⁸

Designated on structure 131 are the strategic bond disconnections that allowed the tracing of the requisite intermediates back to the readily available starting materials. The CO-S linkage was chosen as the key bond for the final coupling reaction.

The aromatic segment 114 (ring C) was synthesized from 3,4,5-trimethoxytoluene as outlined below.³⁹ Compound 132 was diiodinated to give 133, which was monodemethylated to 134 at the less sterically hindered methoxy group, using boron trichloride (Scheme 21). The free hydroxyl group in 134 was protected as the benzyloxymethyl ether 135. Catalytic methoxycarbonylation of 135 furnished the methyl benzoate 136 as the major product (44% yield, accompanied by ca 11% of the regioisomer and 6% of the diester). Finally, removal of the benzyloxymethyl group was achieved under acidic conditions to give 114 (ring C) as a crystalline solid.

Scheme 21. Reagents and conditions: (a) 1.1 equiv l₂, 0.56 equiv HIO₄, AcOH, 53 °C, 93%; (b) 6.0 equiv of BCl₃, CH₂Cl₂, 58% (plus 13% regioisomer and 12% dihydroxy compound); (c) 1.5 equiv PhCH₂OCH₂Cl, 2.0 equiv *i*-Pr₂NEt, ClCH₂CH₂Cl, 70 °C, 100%; (d) 0.05 equiv Pd(OAc)₂, 0.05 equiv Ph₂P(CH₂)₃PPh₂, 2.0 equiv Et₃N, CO atmosphere, DMSO/MeOH (2:1), 70 °C, 44% (plus 11% regioisomer plus 6% dimethyl ester); (e) conc. HCl, MeOH, 89%.

As described below, compound 139 (ring D) was synthesized starting from 137 which, in turn, was made in 60% yield from L-rhamnose, and coupling of 139 with phenol 114 furnished the CD subunit.⁴⁰

Compound 137 (60% yield from L-rhamnose), was selectively methylated at the equatorial 3-hydroxyl group to give 138 (Scheme 22). Acetylation followed by activation of the anomeric position under mild conditions (NBS and DAST) afforded the fluoride 140, and coupling of 140 (ring D) with phenol 114 (ring C) under the influence of silver perchlorate and tin dichloride gave stereospecifically, glycoside 141 in 80% yield.

Scheme 22. Reagents and conditions: (a) 1.1 equiv Bu₂SnO, MeOH, 65 °C, then DMF, 4 equiv MeI, 1.1 equiv CsF, 65%, plus 30% starting material 137; (b) Ac₂O, Et₃N, DMAP cat., CH₂Cl₂, 0–25 °C, 95%; (c) 2.0 equiv DAST, 1.4 equiv NBS, CH₂Cl₂, -78–0 °C, 85%; (d) 1.0 equiv 114, 2.0 equiv 140, 4.0 equiv SnCl₂, 4.0 equiv AgClO₄, 4 Å molecular sieves, CH₂Cl₂, -20–0 °C, 80%; (e) K₂CO₃, MeOH, 100%; (f) TESOTf, 2,6-lutidine, CH₂Cl₂, -20–0 °C, 92%; (g) 2.5 equiv DIBAL-H, CH₂Cl₂, -78–0 °C, 90%; (h) 0.02 equiv. RuCl₃ hydrate, 4.0 equiv NalO₄, CCl₄/MeCN/H₂O (2:2:3), 0–25 °C, 75%; (i) (COCl₂, 100% (crude).

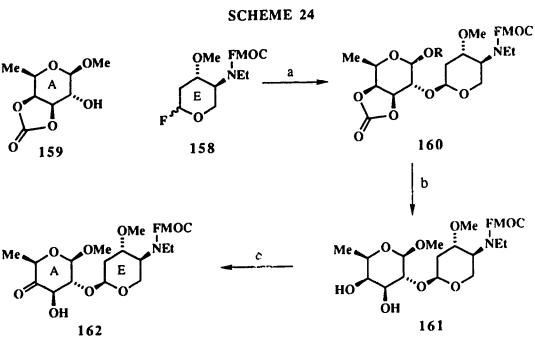

Preference for the formation of the α-anomer under these conditions using a variety of fluorides and alcohols had been demonstrated previously.⁴¹ Deacetylation, protection of the free hydroxyl groups and reduction of the ester to the primary alcohol led to 143. Oxidation to the carboxylic acid 144 and conversion to the acid chloride then afforded the requisite CD subunit 145 in a form suitably set up for eventual coupling with the BAE subunit.

The BAE subunit was synthesized by coupling of a ring B derivative with subunit AE.³⁸ The synthesis of the two isomers 155a and 155b (ring E) proceeded from serine methyl ester hydrochloride 146 (Scheme 23).⁴⁰ Reductive alkylation of 146 with acetaldehyde and sodium borohydride produced the ethyl amine 147 (Scheme 23). Oxazolidone formation gave 148 and this was reduced to aldehyde 149 using diisobutylaluminium hydride. Stereoselective addition of an allyl group to the aldehyde function of 149 was achieved *via* the action of (-)-β-methoxydiisopinocampheylborane and allyl magnesium bromide, leading to a single isomer 150 in 75% yield.

This process therefore introduced the carbons needed for elaboration of ring E and produced the chiral center corresponding to C-3 of ring E. Methylation, followed by ozonolysis, led to the methoxy aldehyde 152, and this was converted to the dimethoxy acetal 153. Removal of the oxazolidone moiety gave 154 which was cyclized under acidic conditions to the desired ring B derivatives 155a and 155b. Protection of the amine (as an FMOC derivative), methyl glucoside hydrolysis, and glycosyl fluoride formation gave 158 (ring E). The compound is properly set up for linkage to a ring A derivative.

Scheme 23. Reagents and conditions: (a) Et₃N, MeOH, 0 °C, 10 min, then MeCHO, 0 °C; then NaBH₄, 0 °C, 64%; (b) carbonyldiimidazole, MeCN, 80 °C, 66%; (c) DIBAL-H, CH₂Cl₂, -78 °C, 75%; (d) 1.3 equiv (-)-β-methoxydiisopinocampheylborane, 1.3 equiv allylmagnesium bromide, THF, -78–25 °C; then pH 7 buffer; MeOH-30% H₂O₂ (3:1), 0 °C, 1 h, 75%; (e) 1.2 equiv Ag₂O, 5 equiv MeI, DMF, 40 °C, 92%; (f) O₃, CH₂Cl₂/MeOH (1:1), -78 °C; then P(OMe)₃, -78–25 °C, 91%; (g) MeOH, Amberlyst-15, 25 °C, 85%; (h) NaOH, MeOH/H₂O (2:1), 90 °C, 96%; (i) HCI, MeOH, 88%; (j) FMOC-Cl, K₂CO₃, THF/H₂O (7:3), 0 °C, 96%; (k) AcOH/H₂O (4:1), 90 °C, 85%. (l) 3 equiv DAST, THF, -78–0 °C, 91%.

Coupling (Scheme 24) of fluoride 158 (ring E) with the suitably protected ring A derivative 159 (synthesized from D-galactose) afforded dissacharide 160 in 70% yield, together with its β -anomer (16%). Chromatographic separation and removal of the carbonate moiety gave the diol 161 which was selectively oxidized at C-4. This sequence furnished ketone 162 which represents a derivative of the subunit AE in a form suitable for coupling with ring B.

Scheme 24. Reagents and conditions: (a) 1.2 equiv 159, 1.5 equiv 158, 2.0 equiv AgClO₄, 2.0 equiv SnCl₂, THF, -78 to -20 °C, 86%, (α / β ratio 4.5:1); (b) 0.01 equiv NaH, HOCH₂CH₂OH/THF (1:20), 93%; (c) 1.0 equiv Bu₂SnO, MeOH, 65 °C, 45 min; then 1.0 equiv Br₂, 1.0 equiv Bu₃SnOMe, CH₂Cl₂, 25 °C, 0.5 h, 70% reas 11% recovered 161.

Ring B was synthesized from the diester 163 which, in turn, was made from D-glucose.⁴² Thus, following selective deprotection of the diester 163, epoxidation of 164 with m-chloroperbenzoic acid followed by regio- and stereoselective epoxide opening by m-chlorobenzoic acid afforded diol 165 in 55% yield (Scheme 25).

SCHEME 25

Scheme 25. Reagents and conditions: (a) DIBAL-H, CH₂Cl₂, -78 °C, 72%, plus 15% recovered 163; (b) 55% *m*-CPBA, MgSO₄, CH₂Cl₂, 0 °C, 55%; (c) *t*-BuMe₂SiCl, imidazole, CH₂Cl₂, 67%; (d) (COCl)₂, DMSO, Et₃N, CH₂Cl₂, -78–25 °C, 88%; (e) Zn(BH₄)₂, NH₄Cl, ether, () °C; (f) HONPhth, DIAD, Ph₃P, THF, 53% overall from 166; (g) N₂H₄, MeOH, 92%.

Selective silylation of the 3-hydroxyl group of 165 followed by exposure to Swern conditions resulted in formation of enone 166 via an oxidation-elimination sequence. 1,2-Reduction of the enone proceeded smoothly from the β -face and was followed by the expected⁴³ in situ ester migration, to afford the desired α -lactol 167 (ca 8:1 α : β ratio) in good yield. Rapid workup, followed immediately by addition of N-hydroxyphtalimide,

triphenylphosphine, and diisopropyl azodicarboxylate resulted in formation of the β -glycoside 168. An S_{N2} process is thought to be occuring here, because the α : β ratio of the resulting glycoside 168 is dependent upon the ratio of the starting lactol anomers. Liberation (hydrazine) of the amino group led to the hydroxylamine derivative 169 (ring B). Again, this compound is suitably set up for coupling with the AE subunit 162.

Coupling of ketone 162 (ring AE) with hydroxylamine 169 (ring B) led to trisacharide 170 (ring BAE) via oxime formation (Scheme 26).³⁸ Silylation of 170 and exposure to DIBAL-H gave the hydroxy compound 172. The latter was treated with thiocarbonyldiimidazole to give the key thionoimidazolide 173. Thermolysis of 173 resulted in a [3,3]-sigmatropic rearrangement which produced thioester 174 and thereby introduced the sulfur moiety at C-4 of ring B. Exposure of the thioimidazolide 174 to sodium methylthiolate led to the rather labile thiol 175 (95% crude yield). Compound 175 represents the BAE subunit.

Coupling of thiol 175 (subunit BAE) and acid chloride 145 (subunit CD) afforded the CDBAE subunit 176 (Scheme 27). Monodesilylation of the enol ether moiety (1.0 equiv Bu₄NF) resulted in the ketone 177. This was selectively reduced with K-Selectride to afford the axial α-hydroxy compound 178 in 75% overall yield from 176. Removal of all three triethylsilyl groups from 178 and removal of the FMOC group then led to 180 in 87% overall yield. Finally, reduction of the oxime double bond in 180 with sodium cyanoborohydride in methanol furnished the target oligosaccharide 131, together with its C-4 epimer (90% yield, *ca* 1:2 ratio). The correct (minor)

isomer was isolated and compared with a closely related derivative made by degradation of calicheamicin $\gamma_1{}^{\rm I}$.

SCHEME 26

Scheme 27. Reagents and conditions: (a) 1.3 equiv 145, 1.0 equiv 175, 5 equiv Et3N, DMAP cat., CH2Cl2, 0 °C, 80%; (b) 1.0 equiv TBAF, 4.0 equiv AcOH, THF, -23 °C,; (c) K-Selectride, DME/THF (8:1), -78 °C, 75% overall from 176; (d) HF.pyridinc, CH2Cl2/THF (15:1), 0 °C, 87%; (e) Et2NH/THF (1:1), 100%; (f) NaBH3CN, MeOH-HCl(g) (pH 3), 0 °C, 90%, ca 1:2 ratio in favor of the wrong isomer.

II. RESULTS AND DISCUSSION

From the above review it is clear that a great deal of research has been directed towards the total synthesis of calicheamicin γ_1^{-1} . The perceived importance of the compound and its analogs, both for the purpose of understanding their biological properties and as a challenge to synthetic chemistry, will no doubt stimulate further work in this field.

The subunit of calicheamicin γ_1^{I} that seemed to pose an obvious challenge from the synthetic point of view is the aglycon portion, calicheamicinone, and we decided therefore that it would be our target.

After a very brief investigation directed towards simple models of the central core, we decided to undertake the synthesis of the actual core itself. It was appreciated of course, that this would constitute a major undertaking and we recognized that the presence of the urethane functionality would be a serious complicating factor.

At the time we started the synthesis, every single report relating to calicheamicin synthesis was on models, and all lacked the urethane moiety. Only very recently was the total synthesis of calicheamicinone reported by Danishefsky et al.³² and it has been made very clear that 'the elusive urethane' as they qualified it, did indeed pose a serious problem.

In the fellowing paragraphs, three different preliminary studies will be discussed:

A) Model studies that probe the viability of an intramolecular palladium-mediated coupling of a vinyl iodide with a vinyl stannane for the construction of the conjugated diene of calicheamicinone (Equation 3).

Pd- catalyst
$$t$$
-BuOPh₂SiO OBn

$$R = Me_3Sn$$

Eq. 3

B) An approach based on radical cyclization that would set up an advanced skeleton related to calicheamicinone in a few steps (Equation 4).

C) An approach based on a Diels-Alder reaction for construction of the six-membered ring of calicheamicinone in a way that provides the nitrogen functionality at C-10 that is needed for elaboration to the target (Scheme 28).

--

[#]The numbering of the carbons is the one designated for calichaemicinone (Scheme 28). The same numbering will be used througout the discussion for compounds representing potential precursors of calicheamicinone.

As the first two approaches met with limited success, we will present the results together with some general outlines only. The third approach looks, at the present time, much more promising and it will be discussed in greater detail.

A) PALLADIUM COUPLING APPROACH

Our first approach was to evaluate a palladium-mediated coupling that would lead to the conjugated diene portion of calicheamicinone. The target molecule of this sequence was 181.

According to our plan, 181 would be constructed by aldol condensation of iodo aldehyde 182 with stannyl enolate 183, to give 184, followed by intramolecular palladium-catalyzed coupling of the two moieties (Equation 5).

The first routes envisioned for preparation of the iodo aldehyde 182 involved either directed hydroalumination⁴⁴ of the mono protected diol 185 followed by treatment with iodine (Scheme 29) to give 187, or treatment with tributyltin hydride/AIBN to give 188, and then with iodine⁴⁵ to give 187. Both methods proved to be unsatisfactory and a better route was devised. This route will be discussed later (Scheme 32).

SCHEME 29

TBDMSO OH

TBDMSO Y

186
$$Y = i - Bu_2Al$$

187 $Y = I$

188 $Y = Bu_3Sn$

The stannyl ketone 190 (cf. 183) was easily made in four steps from the known ester 189,46 as shown in Scheme 30.

SCHEME 30

Scheme 30. Reagents and conditions: (a) DIBAL-H, CH₂Cl₂, -78 °C, 87%; (b) DMSO, (COCl)₂, CH₂Cl₂, -78 °C, 15 min followed by Et₃N, -78 °C, 30 min, 66%; (c) MoMgBr, Et₂O, -20 °C, 95%; (d) as in (b), 65%.

Alternatively, treatment of ester 189 with Tebbe's reagent 191 (Equation 6) gave enol ether 192 which, after flash chromatography on silica, gave the desired ketone 190 directly (26%) along with large amounts of recovered starting material. Although the yield is rather low, we believe that the yield can be raised to a much higher value by using better quality reagent; however this opinion was not tested.

Aldol condensation of ketone 190 with aldehyde 182 proceeded well, providing that the deprotonation step was not done at too low a temperature (-35 °C) (Scheme 31). The crude aldol product was converted into the silyl ether 184 (57% overall). Attempted palladium-mediated coupling resulted in total decomposition (baseline material on TLC). Brief attempts to homolyze the carbon-iodine bond, so as to form a radical that could undergo 6-endo closure were also unsuccessful. Likewise, treatment of 184 with butyllithium, in the hope of generating a carbanion by halogen-lithium exchange, were unpromising, and so the general approach of Scheme 31 was abandoned.

Scheme 31. Reagents and conditions: (a) LDA, Et₂O, -55 °C, 40 min, cool to -78 °C; add 182, 15 min; (b) *t*-BuOPh₂SiCl, Et₃N, DMAP, CH₂Cl₂, 57% overall; (c) (Ph₃P)₄Pd, CH₃CN; or PdCl₂(CH₃CN)₂, CH₃CN; or Bu₃SnH, AIBN, PhH, reflux; or BuLi, THF, -78 °C.

(B) RADICAL CYCLIZATION APPROACH

The second strategy was based on an intramolecular radical cyclization. It was thought that treatment of compound 193 with tributyltin hydride and AIBN under standard conditions would generate the vinyl radical 194 (Equation 7). This could undergo two consecutive 6-exo trig radical closures so as to lead to 195 which represents a relatively advanced precursor of calicheamicinone.

Judicious bond disconnection in 193 suggests three synthons, a valerolactone unit, acetonitrile, and a vinyl iodide 196 that is accessible from the previously discussed iodoaldehyde 182 The preparation of the iodide 182 was achieved as follows:

TBDMSO
$$\stackrel{\text{CH}_2\text{CN}}{\longrightarrow}$$
 $\stackrel{\text{O}}{\longrightarrow}$ $\stackrel{\text{H}}{\longrightarrow}$ $\stackrel{\text{CH}_3\text{CN}}{\longrightarrow}$ $\stackrel{\text{CH}_3\text{CN}}{$

Treatment of the known aldehyde 19747 with mercuric chloride and iodine gave a mixture of two isomeric chloroiodides [157 NMR (90 MHz)] 198a and 198b in 96% yield (Scheme 32).

Scheme 32. Reagents and conditions: (a) HgCl₂, I₂, CH₂Cl₂; (b) AcOK, AcOH, 71% overall.

At the time this experiment 6.33 done we were not aware of any report using mercuric chloride/iodine as a source of ICl, but we eventually found that it had been used with simple, symmetrical, and non functionalised alkenes.⁴⁸

Treatment of the mixture of chloroiodides 198a and 198b with potassium acetate in acetic acid provided the desired iodoaldehyde as a single isomer in 82% yield. The success of this transformation is based on the fact that unsaturated aldehydes have a very high propensity to isomerize to the *trans* geometry. Therefore the *cis* aldehyde produced from one of the two chloroiodides isomerizes under the reaction conditions, and only the *trans* compound 182 is isolated. [Very few reports of iodo alkenals are found in literature and we first suspected that this was due to their instability. We found however that 182 could be stored in the freezer (-15 °C) for several weeks without significant decomposition.]

Deprotonation of acetonitrile followed by quenching of the resulting enolate with aldehyde 182 gave the aldol adduct (Scheme 33), and this was silylated to 199 (70% overall). Removal of the benzyl protecting group was achieved with boron tribromide so as to afford alcohol 200 (90%). It will be noted that cleavage does not take place to any detectable extent at the allylic position but only at the benzylic position (which, of course, is also allylic). The factors responsible for this regioselectivity are not known. Coupling of 200 with 5-bromo-2(5H)-furanone⁴⁹ 201 gave the required cyclization precursor 193 in 50% yield as a mixture of two isomers (¹³C NMR).

SCHEME 33 CN TBDMSO TBDMSO CN TBDMSO TBD

Scheme 33. Reagents and conditions: (a) CH₃CN, LDA, Et₂O, -78 °C, 30 min; add 182 slowly, 1 h, 71%; (b) TBDMSCI, imidazole, DMF, 35 °C, 16 h, 99%; (c) BBr₃, CH₂Cl₂, 0 °C, 92%; (d) AgOTf, 2,4,6-collidine, 5-bromo-2(5*H*)-furanone 201, CH₃NO₂, 50%; (e) Bu₃SnH, AIBN, PhH, reflux, 202a:202b::1:1 ratio, 30-40%.

Treatment of 193 with tributyltin hydride/AIBN under standard conditions afforded a 1:1 mixture [¹H NMR (200 MHz)] of 202a and 202b in 30-40% yield (four experiments, 25 mg scale). Examination of the reaction mixture by TLC showed that the process was clean and revealed two spots running very close together. The ¹H NMR spectrum of the two compounds indicated disapearance of the vinylic hydrogens in the lactone ring of the starting material. The vinylic hydrogen of each of the two isomers resonated at δ 5.99 (t, J = 3.0 Hz) and δ 6.12 (t, J = 2.4 Hz), respectively, the signal areas being in a ratio of 1:1. The high resolution mass spectrum showed peaks corresponding to [M - Me]+, [M - C₄H₉]+ and [M -CH₂CN]+. The FT-IR spectrum contained a weak absorption at 2260 cm⁻¹, corresponding to the nitrile, and a strong absorption at 1800 cm^{-1} , characteristic of a δ -lactone.

Attempts to improve the yield by using different conditions (triethylborane, tributyltin hydride, room temperature; triphenyltin hydride, AIBN, 80 °C;tributyltin hydride, AIBN, 110 °C) all proved unsuccessful. The reason for the low yield (even though TLC monitoring suggested that the reaction was clean) was discovered when the crude mixture from one of the experiments was analyzed by ¹H NMR.

A side product, in a molar ratio of ca 1:1 with the cyclized products, was detected. This side product is totally invisible by TLC but was nevertheless isolated and identified as structure 204 (in which the Z geometry is an arbitrary assignment) (Equation 8). The compound arises quite probably by abstraction of the hydrogen present on the acetal molety by the vinyl radical, followed by C-O cleavage to produce an allylic radical 203. This leads to 204 after hydrogen abstraction from stannane.

Attempts to do the cyclization using the corresponding aldehyde 208 were also conducted (Scheme 34). The rational behind this decision was that aldehydes have been shown to be excellent radical acceptors, 50 and this property would favor the second cyclization. Using the same conditions as for 193, a compound tentatively assigned structure 209, on the basis of its ¹H NMR spectrum was obtained in 31% yield. The synthesis of the aldehyde precursor 208 is shown in Scheme 34. The yields were not optimized.

The fact that only a single cyclization would take place with both nitrile and aldehyde was not a serious problem because, in principle, the second cyclization could be performed using ionic chemistry (aldol).

However, the yield of this single cyclization would have to be improved, and it was decided to perform the cyclization with esters 212 to 214 as opposed to acetals 193 or 208. The possibility of hydrogen abstraction would then be avoided.

The preparation of cyclization precursors **212** to **214** is shown in Scheme 35 where the structures are tentatively assigned on the basis of ¹H and/or ¹³C NMR spectra.

Scheme 34. Reagents and conditions: (a) CH₂CHCH₂MgBr, Et₂O, -78 to -40 °C, 30 min, 69%; (b) TBDMSCl, imidazole, DMF, 55 °C, 6 h, 93%; (c) BBr₃, CH₂Cl₂, 0 °C followed by Ag₂O, acetone-water, 39% overall; (d) 5-bromo-2(5*H*)-furanone 201, Ag₂CO₃, 4 Å molecular sieves, CHCl₃, 61%; (e) OsO₄, NMMO, acetone-water; then NaIO₄, McOH, 50% overall; (f) Bu₃SnH, AIBN, PhH, reflux, 31%.

SCHEME 35

Scheme 35. Reagents and conditions: (a) DEAD, Ph3P, 2-(Phenylthio)-butanedioic 1-methyl ester, 78 °C; (b) ACS, THF-CCl4; (c) DBU, CH2Cl2, 70% overall; (d) m-CPBA, CH2Cl2, 80%.

Treatment of 212 to 214 (Equation 9) with tributyltin hydride/AIBN under standard conditions gave invariably an intractable mixture for reasons that are not clear, although we feel that restricted rotation around the CO-O and, which prevents the molecule from adopting the correct conformation the cyclization to take place, is probably responsible, in part, for this negative result.

Reagents and conditions. (a) Bu₃SnH, AIBN, PhH, reflux.

Prompted by these discouraging results,# the radical cyclization approach was put aside, at least for the time being, while another strategy was evaluated.

(C) DIELS-ALDER APPROACH

The target molecule being sought is a six-membered ring, such as 215, that is suitably functionalised to accept a dilithioenediyne moiety 216 and form, thereby, the framework 217 of calicheamicinone (Equation 10).

Retrosynthetic analysis of the six-membered ring 215 leads to 220 which, in turn, leads to two synthons that could be joined by Diels-Alder reaction. These synthons are diene 218 and dienophile 219 (Equation 11).

TMSO +
$$\frac{11}{MeO_2C}$$
 + $\frac{NO_2}{MeO_2C}$ Eq. 11

For a review on successful and unsuccessful lactonizations by radical chemistry, see reference 51.

The features that make dienophile 219 a potentially good candidate are:

1) It would be a reactive dienophile and so allow the Diels-Alder cycloaddition to occur at a low temperature. One can imagine a process whereby 220 could aromatize to 221 (Equation 12) and such a possibility would be minimized at low temperature. A survey of the literature showed that indeed, 219 had been used⁵² in Diels-Alder reactions and proved to be quite reactive.

- 2) Compound 219 must react in the desired regiochemical sense. The nitro group being potentially an excellent director suggested that the nitrogen group might end up α to the ketal, and we later found a report^{52a} in the literature that this was indeed the way that 219 would behave.
- 3) Reaction of 218 with dienophile 219 would produce 220, which possesses the nitrogen functionality (NO₂) required for future elaboration into the urethane moiety of calicheamicinone. Moreover a carbonyl moiety (CO₂Me) is present and this should be easily converted into the corresponding aldehyde.

The important features of the diene 218 are:

- 1) Reaction of diene 218 with dienophile 219 would provide 220 with the two ketone functionalities necessary for elaboration into calicheamicinone but, more importantly, with one ketone differentiated from the other as an ethylene ketal.
- 2) The fact that diene 218 has similar features to those present in Danishefsky's diene 222 (a well known reactive diene) implies that it will be at least as reactive and possibly more so because two oxygens atoms (ethylene ketal) are present as compared to only one (OMe) in 222. Moreover, the two oxygens atoms are locked in a conformation where two of their electron-pairs orbitals, are perfectly aligned with the π orbitals of the diene moiety, for full conjugation with the latter. The net result is a more efficient activation of the diene.

- 3) The tail present in diene 218 would provide, after ozonolysis of the terminal double bond to generate an aldehyde, the two carbon unit present in calicheamicinone, with the terminal carbon bearing an oxygen functionality.
- 4) The tail will not make the diene particularly high-boiling. This is an important attribute if one considers that, quite likely, the only way of

purifying the potentially very moisture sensitive ketene acetal derivative 218 will be by distillation.

5) The presence of the ethylene ketal, as opposed to a dimethoxy ketal could play a major role in preventing aromatization of the core 220. Indeed, if, under the conditions used for preparing 220, bases or acids are present (which will be the case), elimination of one oxygen of the ethylene ketal could take place. However this process would be reversible (Equation 13). In contrast, if the same reaction occurs with the dimethoxy derivative 223, reversibility is negligible and the intermediate 224 will be likely to aromatize easily (Equation 14).

While the synthesis of diene 218 was being developed, some preliminary studies were undertaken on models in order to evaluate the ease of aromatization of compounds of similar type to 220.

Diene 226 is easily accessible^{52b} and was used in these model studies. Treatment of 226 with methyl nitroacrylate at room temperature, followed by treatment, in situ, with TBAF afforded the benzene derivative 225. Aromatization had indeed taken place easily.

We then came across a report by Danishefsky et al^{52a} which proved to be an invaluable source of information. The reactivity of dienophile 219 with certain dienes (including Danishefsky's Diene 222) had been tested (Scheme 36). As expected, the ease of aromatization of the cycloadduct 227 was not negligible, but interestingly, the latter could be isolated providing that carefully chosen conditions were used. A potential minor problem was apparent, however. The cycloaddition gave rise to a mixture of two compounds 227, epimeric at C-11#, that arose from a transition state where the CO₂Me group of the dienophile 219 had no endo/exo preference and if this happened in our case (i.e. with diene 218), it would be necessary to carry out the subsequent transformations on a mixture of isomers.

[#]The numbering of the carbons is the one designated for calichaemicinone (Scheme 28). The same numbering will be used througout the discussion for compounds representing potential precursors of calicheamicinone.

SCHEME 36

Scheme 36. Reagents and conditions: (a) Neat, 1 h; then HCl (0.005 M) in THF-water, 82%; (b) DBU, THF.

Notwithstanding the danger of aromatization, we felt that an approach to the core of calicheamicinone based on a Diels-Alder reaction should be attempted, and so we carried out the synthesis of diene 218.

The first route involved preparation of bromide 232 by treatment of 5-pentencyl chloride 230 with Meldrum's acid, followed by conversion of the crude adduct 231 to bromide 232 using 2-bromoethanol (Scheme 37). However, for multigram scale synthesis, the corresponding chloro derivative 234 turned out to be more convenient to prepare and we now prefer the route described below.

SCHEME 37

Scheme 37. Reagents and conditions: (a) Meldrum's acid (0.9 equiv), pyridine (2 equiv), CH2Cl2; (b) 2-bromoethanol (3 equiv), PhH, reflux, 55% overall.

The readily accessible methyl β-keto ester 233⁵⁴ was converted to 234 in good yield (ca 66%) by treatment⁵⁵ with 2-chloroethanol in the presence of titanium tetraisopropoxide (Scheme 38). Surprisingly, conversion of 234 into ketene acetal 235 using sodium hydride in THF failed (unlike in the case of bromide 232 where 235 was obtained in 85% yield), but the ketene acetal was eventually prepared (87%) using potassium carbonate in DMF.⁵⁵

Preparation of diene 218 from 235 proved to be troublesome, but was achieved after some effort. The difficulties encountered are, in my opinion, due to two main factors:

Scheme 38. Reagents and conditions: (a) Ti(i-OPr)4, 2-chloroethanol, 75 °C, ca. 66%; (b) K2CO3, DMF, 87%.

1) Compound 218 possesses a ketene acetal moiety conjugated to a carbonyl and, therefore, it is very susceptible to attack by nucleophiles, including enolates. Hence conditions had to be found where no enolate would be formed in the presence of intact 235. This can be achieved easily by slow addition of a solution of 235 to a cold solution of base at a low

temperature (kinetic conditions). However, there is a second complicating factor.

2) The allyl group linked to the diene should preferably be syn to the silyloxy group, since dienes with (E) geometry are known to be rather unreactive in Diels-Alder reactions. The use of normal kinetic conditions (lithium diispropylamide, -78 °C) gives a (7:3) mixture in favor of the wrong isomer 236.

A solution to the problem was found when the reaction was done under kinetic conditions using a different base. When lithium hexamethyldisilazide was used at -78 °C, the desired 218 was the major compound and predominated over the other isomer by a factor of 3 to 2. This result showed that the nature of the base could drastically influence the ratio of isomeric enolates, and indeed, this had been confirmed by a report by Masamune⁵⁶ in which 3-pentanone was deprotonated under kinetic conditions using a wide variety of bases. Many bases afforded different ratios of isomeric enolates. Interestingly, lithium hexaethyldisilazide [(Et₃Si)₂NLi] and (Me₂PhSi)₂NLi gave the desired (Z) enolate almost exclusively.

In our case, treatment of 235 with lithium bis(dimethylphenyl)silazide $[(Me_2PhSi)_2NLi]$ under kinetic conditions, quenching with chlorotrimethylsilane, followed by non-aqueous workup and Kugelrohr distillation gave a solution of the desired diene 218 (ca 100%) in $(Me_2PhSi)_2NH$. The ¹H-NMR spectrum showed a new signal, corresponding to the vinylic hydrogen of the enol ether, which resonated at δ 4.76 (t, J = 7.2 Hz). The methylene hydrogens resonated at δ 2.8--2.92 (m). Although determination of enol ether geometry can be done by ¹H NMR and ¹³C NMR measurements,⁵⁷ this was not attempted, and we assumed that the enol ether obtained by using lithium bis(dimethylphenyl)silazide [(Me₂PhSi)₂NLi] had the (Z) geometry as in the case of 3-pentanone. This assumption was confirmed by determination of the stereochemistry of the allyl substituent of the Diels-Alder adduct (see following experiment).

Attempts to obtain neat diene by careful distillation failed and, therefore, it was decided to use diene 218 in the next step, as a solution in bis(dimethylphenyl)silylamine [(Me₂PhSi)₂NH], in the hope that the amine would not interfere with the reaction.

We now had the material in hand for the Diels-Alder cycloaddition with methyl nitroacrylate 219. Preliminary attempts were disappointingly unsuccessful, but it was soon realized that diene 218 was not stable enough to be kept at -15 °C overnight before use. When the reaction was repeated using 1.5 equiv of freshly-prepared (ca. 1 hour old) diene at 0–25°C followed by brief treatment with dilute hydrochloric acid (0.005M), TLC examination of the reaction mixture after workup showed several (5) spots including a very faint

one. All the compounds were isolated. Four represented byproducts coming from the diene itself and, gratifyingly, the faint spot was the desired compound 237a. It was obtained as a white solid in 81% yield!#

In the event, not only had the Diels-Alder reaction worked in the presence of the amine, but the product 237a was stable enough under these conditions to be isolated. Analysis of the 1H NMR spectrum showed the presence of an isomeric side product (ca. 11-17 mol%) but carefull crystallization afforded the pure major isomer, the mother liquor being enriched in the minor isomer. In the major isomer 237a, the $C\underline{H}CO_2Me$ resonated at δ 3.83 (dd, J = 10.0, 5.0 Hz) and showed a large (axial-axial) coupling with $C\underline{H}NO_2$ as well as a small (equatorial-axial) coupling with $C\underline{H}$ -allyl. In the minor isomer 237b, $C\underline{H}CO_2Me$ resonated at δ 3.55 (dd, J = 10.4, 9.6 Hz) and showed a large (axial-axial) couplings with both $C\underline{H}NO_2$ and $C\underline{H}$ -allyl. It will be noted that both 237a and 237b derive from reaction of our diene 218 with methyl nitroacrylate 219 where the CO_2Me group was *endo* to the diene moiety in the transition state of the Diels-Alder reaction.

[#] For an example of a dithioketene analog of our diene 218, see reference 53. The reported compound met with very limited success as a diene in Diels-Alder reactions.

In contrast, the reaction of Danishefsky's diene 222 (page 184) with the same dienophile, as mentioned previously, gave products that arose from a transition state where the CO₂Me group had no endo/exo preference and therefore an epimeric mixture had ensued. In other words, in our case, the NO₂ group, controlled the regiochemistry of the cycloaddition but was exclusively exo to the diene moiety in the transition state leading to the cycloadduct. Electronic repulsion between the electron rich acetal of the diene and with the nitro group and/or steric hindrance offered by the ketal moiety is presumably responsible for the high stereoselectivity of the process. The formation of two isomers (237a and 237b) is due to some isomerization once the ketone has formed.

We at last had a route that provided a relatively advanced precursor of the central core of calicheamicinone, and from now on all future efforts were concentrated on this approach.

We decided, at this point, to reduce both carbonyl functionalites (ketone and ester) to the corresponding hydroxyls in order to prevent the possibility of aromatization. After considerable experimentation it was found that 237a and 237b (83:17) could be converted into 238a (53%) and 238b (28%) using diisobutylaluminium hydride under carefully adjusted conditions (see experimental).

It is believed that complications originated from elimination of the nitro group, (an unsaturated aldehyde was isolated on one occasion), and also by simple removal of the proton α to the nitro group (the reaction was incomplete when a stoichiometric amount of diisobutylaluminium hydride was used). It will be noted that it is most surprising to observe epimerization at C-13 under aprotic reduction conditions but unusual behavior of the present series of nitro compounds will manifest itself again in many subsequent steps.

Although, in principle, both isomers could be utilized, only the major diol 238a was used and it was converted to the corresponding silyl ether 239 (91%). The stereochemistry of diol 238a and its silyl ether 239 were unambiguously assigned at a later stage.

1) Studies aimed at introducing the C-13--C-15 portion stereospecifically

Our next task was to investigate how the tail (C-13 to C-15) could be obtained, and therefore our goal was selenide 240 (equation 15). Oxidation of the latter followed by selenoxide elimination would produce an α,β -unsaturated aldehyde 241 which contains the required unsaturation at C-13

and C-14. The geometry of the double bond has to correspond to the one in calicheamicinone and, since it would be formed by a selenoxide elimination (syn elimination), the stereochemistry of the selenide 240 would control the outcome.

It was not clear, however, if the selenenylation would be stereoselective, and if so, what the nature and extent of the preference would be. However, 239 certainly offered an asymmetric environment that was worth exploiting.

Conversion of 239 to diols 242 by osmylation, followed by cleavage using sodium periodate, afforded aldehyde 243 in 82% overall yield (scheme 39) Conversion to the silyl enol ethers 244a and 244b, and quenching in situ with an excess of benzeneselenenyl chloride (-20 °C) afforded the corresponding selenides 245a and 245b in a ratio of 4:1 (92%). The stereochemistry of the selenides was assigned on the basis of the results that were later obtained with 254a and 254b (see later).

The environment offered by 243 therefore does favor one isomer over the other and the selectivity is probably acceptable, but the major compound is the undesired isomer.

SCHEME 39

$$RO^{NO_2}$$
 RO^{NO_2}
 $RO^{$

R = TBDMS

Scheme 39. Reagents and conditions: (a) OsO4, NMMO, acetone-water; (b) NalO4, MeOH, 82% overall; (c) TMSCl, Et₃N, ZnCl₂, PhH; (d) add PhSeCl at -20 °C, ratio 245a:245b::4:1, 92% overall.

Isolation and analysis by ¹H NMR of the intermediate silyl enol ethers 244b and 244a shows an 8:1 mixture (¹H NMR) of (*E*) and (*Z*) isomers, respectively. It is interesting to note that although, under thermodynamic conditions, simple aldehydes give mainly the (*Z*) enol ether (7:3 in the case of butanal),⁵⁸ 243 behaves differently. More interesting though is the result obtained when a small amount of the (*Z*) enol ether 244a was isolated by flash chromatography and treated with benzeneselenyl chloride (-20 °C).

The major seleno aldehyde was now the desired one (245b:245a::8:1) and the interpretation of this outcome is, of course, that the (Z) enol ether 244a leads mainly to the desired selenide 245b whereas the (E) isomer leads to the undesired 245a.

Attempts to get a high proportion of (Z) enol ether failed, the best result being 244b:244a::2:1, and, therefore, this strategy was put aside. Before doing so, it was necessary to ensure that the stereochemistry indicated for the selenides 245a and 245b was correct and the assignment was established as follows:

After conversion of the selenides to the corresponding α,β unsaturated aldehydes (Scheme 40), selective deprotection of the primary alcohol will lead, in one case, to lactols 247 which, of course would have no aldehyde signals in the ¹H NMR spectrum, and in the other case to aldehyde 248. The presence or the absence of an aldehyde signal in the ¹H NMR spectrum would therefore indicate the geometry of the double bond and, by correlation, the stereochemistry of the selenides.

It was decided to conduct this study on the triethylsilyl urethane derivative 249 because, in the event that the stereoselectivity can be forced to favor the desired isomer - a possibility not yet established - the chemistry developed could be employed for further elaboration directly towards calicheamicinone. It should also be pointed out that preliminary results had indicated that selective deprotection of the primary alcohol in the bis-t-

butyldimethylsilyl series was not efficient enough. Hence the more labile triethylsilyl derivative was prepared as described later.

TBDMSO NO2 TBDMSO NO2

R = t-BuMe₂Si or Et₃Si

Olefin 250 (R = Et_3Si) was hydroxylated to 251 (R = Et_3Si) in 95% yield, and it was decided to hydrogenate the nitro group to an amine function at

this stage (Scheme 41). The diol plays the role of masking the double bond and so protects it against hydrogenation. It also serves as a handle for In the event, this apparently simple producing the aldehyde 253. hydrogenation required a very great effort extending over several months.

SCHEME 41

R = t-BuMe₂Si or Et₃Si

256

Scheme 41. Reagents and conditions: (a) OsO4, NMMO, acetone-water, 95%; (b) H2, Raney Nickel, 2:1 ethanol-methanol; then ClCO2Me, Et3N, CH2Cl2, -30 °C, 45% overall; (c) NalO4, MeOH, 65%; (d) TMSCl, Et3N, PhH followed by addition of PhSeCl at -20 °C, ratio 254a:254b::3:1; (e) 30% aqueous H2O2 (6 equiv), pyridine (12 equiv), CH2Cl2-THF, ratio 255a:255b::7:3, 39%; (f) TFA (3 equiv), THF-water, ratio 257:256::7:3.

Eventually, it was found that treatment of 251 (R = Et₃Si) with Raney Nickel under carefully adjusted conditions (see later) and conversion of the resulting crude amine to carbamate 252 (R = Et₃Si) could be achieved in 45% overall yield (Scheme 41). [The corresponding transformations in the bis-tbutyldimethylsilyl series (251=242, R = t-BuMe₂Si) were also performed and gave urethanes 252 (R = t-BuMe₂Si) in 55% yield.] Cleavage of diol 252 (R = Et₃Si) with sodium periodate gave the desired aldehyde 253 (R = Et₃Si) in 65% yield (85% for the bis-t-butyldimethylsilyl series). Surprisingly, the aldehyde was a mixture (3:1) of isomers. This was the cause for some concern for a long time but it was later established that the formation of a mixture was due only to rotational isomerism involving the urethane (see later). Selenenylation of 253 (R = Et₃Si) as before (the enol ethers could not be isolated) gave isomeric selenides 254a and 254b (R = Et₃Si) in a 3:1 ratio.# The corresponding ratio when R = t-BuMe₂Si was 5.3:1. Conversion of 254a and 254b ($R = Et_3Si$) to unsaturated aldehydes 255a and 255b (R = Et₃Si) (3:1 ratio)# was achieved in modest yield (39%). (Again, the corresponding ratio when R = t-BuMe₂Si was 5.3:1).# Treatment of the monotriethylsilyl derivative 255a and 255b (7:3 ratio)# with trifluoroacetic acid in cold (0 °C) aqueous THF gave cleanly 256 and 257 in approximately the same ratio# as the starting material. The signal from the minor aldehyde that was previously at δ 9.90 had dissapeared and the one corresponding to the major aldehyde was still present but had shifted slightly from δ 10.55 to δ 10.69. These results establish that the major isomer 245a was the undesired one and therefore this approach for introduction of the double bond at C-13 and C-14 was abandoned.

[#] Each of the compounds was itself a mixture of (urethane) rotamers. For further discussion see p 201]

The next strategy explored to control the stereochemistry of the tail is one that uses some inherent features of the molecule itself, because it was planned to tie the tail to the hydroxymethylene group to form a lactone. Compound 258 became, therefore, the immediate goal. It has a number of potentially useful features, as will become clear.

Compound 258 was synthesized from the Diels-alder adducts 237a and 237b as follows:

Treatment of 237a and 237b (83:17) with sodium borohydride (97%) produced a mixture of three isomeric alcohols 259 which could be silylated in excellent yield provided that the silylating agent (t-butyldimethylsilyl triflate) was added <u>immediately</u> after injection of 2,6-lutidine (Scheme 42). Failure to do so resulted mostly in recovery of starting material which would not react further even on addition of more reagent. The mixture of the three isomers was chromatographed, after which 260 was isolated (63%) and the remaining two isomers (25%) were left aside. The stereochemistry shown for 260 was determined on the basis of its 1 H NMR spectrum. The CHCO₂Me resonated at δ 3.52 (dd, J = 12.0, 4.5 Hz) and showed a large (axial-axial) coupling with CHNO₂ and a small (equatorial-axial) coupling with CH-allyl. The CHOSiR₃

resonated at δ 4.06 (dt, J = 8.0, 5.0 Hz) and showed a large (axial-axial) coupling with both CH₂ and C<u>H</u>-allyl, as well as a small (equatorial-axial) coupling with one of the CH₂ hydrogens.

SCHEME 42

Scheme 42. Reagents and conditions: (a) NaBH₄, CH₂Cl₂-MeOH, -78 °C to room temperature, 97%; (b) TBDMSOTf, lutidine, CH₂Cl₂ followed by separation, 63%; (c) DIBAL-H, CH₂Cl₂, -30 °C, 87%; (d) OsO₄, NaIO₄, *t*-butanol-THF-water, 98%; (e) PCC, CH₂Cl₂, 77%.

Ester 260 was converted (diisobutylaluminium hydride, -30 °C) to alcohol 261 in good yield (87%) providing that inverse addition of starting material to a cold (-30 °C) solution of the hydride was used. When the reducing agent was added to the substrate, the reaction proceeded only to a slight extent and mainly starting material was recovered.

We have no firm explanation for this unusual behavior, although we suspect that the nitro group, which confers a relatively high acidity to the adjacent hydrogen, is responsible.

The terminal double bond of compound 261# was cleaved (osmium tetroxide, sodium periodate) to provide lactols 262a and 262b (98%) as a mixture of epimers at C-15. Oxidation of 262a and 262b with PCC gave lactone 263 in good yield (77%). This now appeared as the appropriate stage to attempt reduction of the nitro group to an amine for reasons that will become clear after the following observations.

Preliminary results had indicated that the previously discussed hydrogenation of the nitro derivative 251 (Equation 16) over Pd/C did not seem to proceed at all. Many attempts using many combinations of a wide variety of catalysts, pressure, reducing agents and substrates, all led to decomposition, or recovery (50–100%) of starting material.

In a separate study, alcohol 261 was converted to its silyl ether 250 (Scheme 41) and shown to display a ¹H NMR spectrum identical (except for the Et₃Si signals) to the corresponding *t*-BuMe₂Si derivative 239, which was synthesized, as previously mentioned, from 237a by reduction with diisobutylaluminium hydride followed by silylation. This observation therefore leads to the conclusion that both routes i.e. 237a (page 188) to 239 (page 190) and 237a to 260 (Scheme 42) to 250 (Scheme 41) afford the same stereoisomer.

A possible way to avoid the problem of the hydrogenation step was to attempt either sulfenylation α to the nitro group (so as to generate a ketone by hydrolysis) or direct oxidation of the nitro group to a ketone (Nef reaction), but experiments to implement such plans were unsuccessful.

We therefore tried hydrogenation again and it was eventually found after much effort that reduction of 251 to the corresponding amines followed by conversion to the derived urethanes 252 (see footnote page 201), worked in modest and fairly reproducible yields (45%), provided that a specific procedure was followed.

A 7:1 w/w ratio of freshly (< 1 week) prepared Raney Nickel (T-1 grade)# that had been thoroughly washed free of bases had to be used under a modest (50 psi) pressure of hydrogen, and methanol was required to solubilize the starting material sufficiently to allow good contact with the catalyst. When less catalyst was used many side products were formed; using more catalyst gave a clean reaction but recovery of material was drastically lowered. Presumably this was due to adsorption of the amine on the catalyst.

.

[#] See experimental

A way to minimize adsorption of amine on the catalyst had to be found, and so conversion of the very polar diol unit into a lactone was examined, and this is why the previously discussed lactone 263 seemed suitable. Hydrogenation of nitro lactone 263 was attempted and, although the conditions that had been optimized for 251 were used, the results were, unfortunately, not promising enough to warrant further investigation. Poisoning of the catalyst still seemed to take place.

In a final attempt to overcome the problems, it was decided to try hydrogenation on the protected lactol 266 (Scheme 43).

It will be noted that the urethanes 252 were a mixture of isomeric diols. We suspected that (urethane) rotamers were involved as well, and this was confirmed as follows. The mixture of isomers 252 was converted in three steps to urethane-lactone 264. At this point the 1H NMR spectrum still showed a 3:1 mixture of isomers as evidenced by the presence of two singlets (COOMe) at δ 3.69 and δ 3.70. However, The 1H NMR spectrum of the same sample heated at 50 °C significantly simplified (only one singlet at δ 3.70) and this led to the conclusion that the compound exists as two isomers arising from the restricted rotation about the NH–CO2Me bond of the urethane unit.

Silylation of lactols 262a and 262b gave 266 as a single isomer in 96% yield. The 1H NMR spectrum showed that CHOSiEt3 resonated at δ 4.67 (dd, J = 9.0, 2.2 Hz). There was a large (axial-axial) coupling as well as a small (axial-equatorial) coupling with CH₂. Hence, the triethylsilyloxy group is equatorial, i.e. α .

Hydrogenation of 266 under the usual conditions [carefully washed Raney Nickel T-1, H₂ (50 psi)] gave the desired amine 267 in 89% yield!

SCHEME 43

Scheme 43. Reagents and conditions: (a) Et₃SiCl, Et₃N, DMAP, CH₂Cl₂, 96%; (b) H₂, Raney Nickel, ethanol-methanol, 89%.

At long last, efforts could now be concentrated on elaboration of the amine into more advanced intermediates, and two routes were investigated.

(a) First route

In the first route, amine 267 was cleanly converted (trifluoroacetic anhydride, pyridine, -30 °C) to carbamate 268 (R = COCF₃) (ca. 75%) along with a small amount of the corresponding lactols 268'(ca. 10%) (Scheme 44 and page 204). (When the reaction was carried out at 0 °C to room temperature, only the lactols were obtained). The products 268 and 268' were purified (SiO₂) and combined for the next step.

SCHEME 44

 $R = CO_2Me \text{ or } COCF_3$

Scheme 44. Reagents and conditions: (a) TFAA, DMAP, pyridine, -30 °C; (b) PCC, CH₂Cl₂, 85% overall; (c) LDA, -78-0 °C, 30 min, followed by addition of PhSeBr at -78 °C, 64%; (d) 30% aqueous H₂O₂, pyridine, CH₂Cl₂-THF, 92%.

PCC oxidation of the mixture gave lactone 269 (R = COCF₃) in 85% yield overall yield. It will be noted that prior removal of the triethylsilyl group is not necessary as it is lost under the reaction conditions, to give the corresponding lactols 268' which are oxidized to the lactone.

Compound 269 was converted cleanly to the selenide 270 in 64% yield. As expected, attack of benzeneselenyl bromide proceeded from the less hindered face of the molecule, i.e. the β -face. Moreover, the newly introduced phenylseleno group is syn to the hydrogen to be abstracted at C-13. Oxidation gave the corresponding selenoxide and this collapsed easily to the desired α,β -unsaturated lactone 271 in excellent yield (92%). It will be noted that by using this strategy, the geometry of the double bond has been totally controlled in the desired sense.

The reason why carbamate 269 ($R = COCF_3$) as opposed to urethane 269 ($R = CO_2Me$) was used is because selenenylation of the latter [synthesized from amine 267 using the same type of route as the one used for the carbamate269 ($R = COCF_3$) (Scheme 44)] under similar conditions, gave the desired selenide 270 ($R = CO_2Me$) only in poor yield (30%).

corresponding urethane 268 (R = CO₂Me) (methyl chloroformate, triethylamine) gave variable results depending on the exact conditions. Invariably only a little (ca. 15%) of the desired urethane was formed, and instead a relatively very non-polar compound (TLC), that was somewhat unstable to silica, was isolated. It was identified as isocyanate 272.

Clearly, the urethane moiety had a tendency to eliminate methanol and, therefore, it was no surprise, that some complications arose when the urethane $269 (R = CO_2Me)$ was subjected to strongly basic (lithium diisopropylamide) conditions in the selenenylation step.

The carbamate function, however was satisfactory, and it had the advantage of being potentially easily removed under mild conditions (methanolic potassium carbonate).⁵⁹

Therefore, once the unsaturated lactone was introduced, we had planned to remove the protecting group to give the amine 273 (Scheme 45).

Oxidation of the amine to the imine would be followed by tautomerization to the target enamine 275.

TBDMSO" TBD

Unfortunately, the protecting group was more resistant than expected, and preliminary attempts to remove it under less mild conditions (methanolic sodium hydroxide) did not result in formation of the desired amine 273, or of any identifiable product. Quite certainly the complications arise from the fact that the lactone portion is affected by these conditions. For this reason, the approach involving the carbamate was temporarily set aside and a second approach was investigated.

(b) Second route

273

Our plan was to try to generate the enamine portion and *then* to generate the unsaturated lactone. Attempts to convert amine 267 to ketone 278 in one operation (sodium hypochlorite, phase transfer conditions),⁶⁰ were not successful (Scheme 46). Such experiments led to the formation of a mixture of monochloroamine 276 and its dichloro analog. The conversion was, however, achieved in two steps.

Treatment of 267 with 1.0 equiv of tert-butylhypochlorite gave the monochloride 276 in 77% yield and treatment of 276 with DBU gave presumably the im¹ te 277. This was not isolated but underwent hydrolysis to ketone 278 (87%) (v_{max} C=O 1738 cm⁻¹), which was the compound actually obtained.

TBDMSO TB

Scheme 46. Reagents and conditions: (a) t-BuOCl, THF-Et₂O, -45 °C, 77%; (b) DBU, PhCH₃, 100 °C, 2 h; (c) aqueous NH₄Cl, 15 min, 87% overall.

Some imines had been converted to their corresponding enamides (acetic anhydride, 160 °C, acid)# but we had other plans in mind.

[#] For a review on preparation and photochemistry of enamides, see reference 61.

Ketone 278 was converted to the stable oxime derivatives 279a and 279b in good yield (75%, ratio 1:1) (Scheme 47).

SCHEME 47

Scheme 47. Reagents and conditions: (a) BnONH2.HCl, pyridine, EtOH, molecular sieve 4 Å, 75%; (b) PCC, CH2Cl2, 90%; (c) LDA, -78 °C, 90 min followed by addition of PhSeBr at -78 °C, 82%; (d) dimethyl dioxirane in acetone, *ca* 100% crude; (e) SiO₂

Gratifyingly, the triethylsilyl group resisted to a very large extent (but not completely) these conditions. Oximes have also been converted to enamides (acetic anhydride, pyridine, 160 °C),61 but we planned to attempt this transformation later , as our oxime functionality represents a suitable protecting group for nitrogen while we elaborate the lactone moiety.

It will be noted that so far, in this series of transformations, not only the nitrogen functionality was reintroduced but a new unsaturation was created.

PCC oxidation of 279a and 279b gave 280a and 280b directly in excellent yield (90%) (v_{max} C=O 1737 cm⁻¹). Selenenylation of 280a and 280b in the presence of the now suitably protected nitrogen, then afforded 281a and 281b in 82% yield. The success of this last transformation was most pleasing because we did not know beforehand if deprotonation (lithium diisopropylamine) would take place α to the lactone or α to the oxime. Lithium diisopropylamide has been used previously for generation of enolates of both oximes and lactones; we were not aware, however, of any examples where generation of the enolate of one functionality had been selectively achieved in the presence of the other.

We then proceeded to the next step and, surprisingly, oxidation of 281a and 281b (m-chloroperbenzoic acid or 30% hydrogen peroxide) followed by flash chromatography gave very little of the desired compound 282a and 282b, as evidenced by the absence of the typical triplet at δ 6.15, which corresponds to the vinyl hydrogen at C-14. Oxidation of 281a and 281b with sodium periodate in THF, and analysis of the crude mixture (1 H NMR) showed what could be identified as the desired compounds, but the latter were contaminated with unidentified byproducts. Attempts to purify the desired lactones 282a and 282b by flash chromatography led to recovery of the same material that was observed when m-chloroperbenzoic acid or 30% hydrogen peroxide had been used as oxidizing agent.

We therefore came to the conclusion that the desired material was unstable to silica, and so purification was avoided by oxidizing 281a and 281b with dimethyl dioxirane in acetone (-78 °C to room temperature). This operation gave cleanly (107% crude yield, > 95 mol% pure by 1H NMR) the desired α,β -unsaturated lactone 282a and 282b. The 1H NMR spectrum showed a mixture of two isomeric oximes in a 1:1 ratio with the vinylic hydrogen of the isomers resonating at δ 6.15 (t, J = 2.2 Hz) and δ 6.12 (t, J = 2.2 Hz), respectively. The ^{13}C NMR spectrum had the expected number of signals in the C=C region and the IR spectrum showed a strong absorption at 1733 cm- 1 , characteristic of an α,β -unsaturated lactone.

When this material was left in contact with silica gel for 15 min and then subjected to flash chromatography, it was converted cleanly to isomers 283a and 283b. The structure is tentatively assigned, mainly on the basis of the disappearance of the vinylic signals in the ^{1}H NMR spectrum, the infrared absorption at 1748 cm $^{-1}$, which indicates the presence of a lactone that is not α,β -unsaturated, and on the basis of the observation of the expected ion $(M-C_4H_9)^+$ in the high resolution mass spectrum.

--Conclusion--

This section of the thesis describes:

- a) The preparation of a novel diene and its successful use in a Diels-Alder reaction.
- b) The construction of a potential precursor to the central core of calicheamicinone.
- c) Elaboration of this precursor to a level where both unsaturations necessary for preparation of the diene moiety have been introduced. The geometry of

the double bond at C-13 and C-14 is controlled and, in a very few steps, an advanced intermediate suitable for coupling with dilithioenediyne should be accessible. A resume of the two most promising routes is shown in (Scheme 48 to 50).

Scheme 48. Reagents and conditions: (a) neat, 0 °C, 1 h; then mild acid; (b) NaBH₄, CH₂Cl₂-MeOH, -78 °C to room temperature, 97%; (c) TBDMSOTf, lutidine, CH₂Cl₂, followed by separation, 63%; (d) DIBAL-H, CH₂Cl₂, -30 °C, 87%; (e) OsO₄, NaIO₄, *t*-butanol-THF-water, 98%; (f) Et₃SiCl, Et₃N, DMAP, CH₂Cl₂, 96%; (g) H₂, Raney Nickel, ethanol-methanol, 89%.

SCHEME 49

Scheme 49. Reagents and conditions: (a) TFAA, DMAP, pyridine, -30 °C; (b) PCC, CH₂Cl₂, 85% overall; (c) LDA, -78 °C to 0 °C, 30 min, followed by addition of PhSeBr at -78 °C, 64%; (d) 30% aqueous H₂O₂, pyridine, CH₂Cl₂-THF, 92%.

SCHEME 50

Scheme 50. Reagents and conditions: (a) t-BuOCl, THF-Et₂O, -45 °C, 77%; (b) DBU, PhCH₃, 100 °C, 2 h, followed by aqueous NH₄Cl, 15 min, 87%; (c) BnONH₂.HCl, pyridine, EtOH, 4 Å molecular sieves, 75%; (d) PCC, CH₂Cl₂, 90%; (e) LDA, -78 °C, 90 min, followed by addition of PhSeBr at -78 °C, 82%; (f) dimethyl dioxirane in acetone, ca 100% crude.

On the basis of our findings, the following synthetic routes (among others) suggests themselves (Scheme 51 and 52). Which route is the most promising is impossible to evaluate at this point since the behavior of the intermediates involved in the project so far were shown to be most unpredictable. Work currently underway in our laboratory will provide the necessary information.

SCHEME 51

Scheme 51. (a) RCOCl; (b) (i) H⁻, (ii) selective protection; (c) (i) removal of TBDMS group, (ii) oxidation; (d) dilithioenediyne; (e) (i) N-O cleavage (e.g., $Zn-Cu^{62a}$ or $Ra-Ni^{62b}$), (ii) introduction of the trisulfide moiety.³⁴

SCHEME 52

Scheme 52. (a) (i) H^- , (ii) selective protection; (b) (i) oxidation, (ii) RCOCl; (c) dilithioenediyne; (d) (i) N-O cleavage (e.g. Zn-Cu^{62a} or Ra-Ni^{62b}), (ii) introduction of the trisulfide moiety.³⁴

III. EXPERIMENTAL

The general remarks made in Chapter 1 apply:

(Z)-2-Iodo-4-(phenylmethoxy)-2-butenal (182).

(a) 3-Chloro-2-iodo-4-(phenylmethoxy)-2-butanal (198a and 198b). Mercuric chloride⁴⁸ (16.94 g, 62.4 mmol) was added in one portion to a well stirred and cooled (0 °C) solution of iodine (31.67 g, 124.8 mmol) in dichloromethane (250 mL). The mixture was stirred for 15 min, and aldehyde⁴⁷ 197 (10.9 g, 61.8 mmol) was added in one portion. The resulting suspension was then stirred at room temperature for 3 h. The red precipitate was filtered off and the filtrate was washed with 10% w/v aqueous sodium thiosulfate (2 x 100 mL), and water (1 x 50 mL), and dried (MgSO₄). Evaporation of the solvent gave crude 198a and 198b (19.25 g) which was used directly for the next step.

(b) (Z)-2-Iodo-4-(phenylmethoxy)-2-butenal (182). The reaction mixture was protected from light by wrapping the reaction flask with aluminum foil. Potassium acetate (7.66 g, 78 mmol) was added in one portion to a cold (0 °C) and stirred solution of crude 198a and 198b (17.6 g) in glacial acetic acid. The cold bath was removed and the mixture was stirred at room temperature for 16 h. Dichloromethane (400 mL) was added followed by carefull addition of saturated aqueous sodium bicarbonate (1 x 400 mL). The aqueous layer was

extracted with dichloromethane (2 x 300 mL) and the combined organic extracts were washed with saturated aqueous sodium bicarbonate (1 x 400 mL), and water (200 mL), and dried (MgSO₄). Evaporation of the solvent and flash chromatography of the residue over silica gel (80 x 200 mm) using 15% ethyl acetate--hexane gave 182 (12.18 g, 71% from 197) as a slightly yellow oil. The material could be kept in the freezer for several weeks without significant decomposition: FT-IR (CHCl₃ cast) 1700, 1620 cm⁻¹; ¹H NMR (CDCl₃, 300 MHz) δ 4.41 (d, J = 5.4 Hz, 2 H), 4.62 (s, 2 H), 7.29--7.40 (m, 5 H), 7.48 (t, J = 5.4 Hz, 1 H), 8.62 (s, 1 H); ¹³C NMR (CDCl₃, 75.5 MHz) δ 73.48, 73.66, 108.65, 127.95, 128.18, 128.63, 137.12, 158.53, 186.81; mass for C₁₁H₁₁O₂I (chemical ionisation, NH₃) 320 (M + 18)+. Anal. Calcd for C₁₁H₁₁O₂I: C, 43.73; H, 3.67; O, 10.59. Found: C,43.69; H,3.63; O, 10.85.

(Z)-3-[[Dimethyl(1,1-dimethylethyl)silyl]oxy]-4-iodo-6-(phenylmethoxy)-4-hexenenitrile (199).

(a) (Z)-3-Hydroxy-4-iodo-6-(phenylmethoxy)-4-hexenenitrile. Dry acetonitrile (0.75 mL, 14.46 mmol) was added dropwise over 5 min to a cold (-78 °C) and stirred solution of LDA (13.74 mmol) in dry ether (50 mL). Stirring was continued for 30 min at -78 °C, and then a solution of iodo aldehyde 182 (2.5 g, 7.23 mmol) in ether (10 mL + 2 mL rinse) was added over 1 h (syringe pump) to the cold mixture. During the addition, a white precipitate formed. Stirring was continued for 15 min after the end of the addition, and the mixture was then poured into a separatory funnel containing ether (50 mL)

and saturated aqueous ammonium chloride (20 mL). The aqueous layer was extracted with ether (30 mL), and the combined organic extracts were washed with 10% w/v aqueous sodium thiosulfate (1 x 30 mL), and water (1 x 30 mL), dried (MgSO₄) and evaporated. Flash chromatography of the residue over silica gel (40 x 200 mm) using 35% ethyl acetate--hexane gave the desired alcohol [2.0 g, 71% (79% based on conversion)] as a reddish oil.

(b) (Z)-3-[[Dimethyl(1,1-dimethylethyl)silyl]oxy]-4-iodo-6-(phenylmethoxy)-4-hexenenitrile (199). Imidazole (1.74 g, 25.56 mmol) and tert-butylchlorodimethylsilane (1.85 g, 12.27 mmol) were added to a stirred solution of the above alcohol (1.90 g, 4.91 mmol) in dry DMF (10 mL). The mixture was stirred at 35 °C for 16 h and diluted with ether (120 mL). The resulting mixture was washed with water (2 x 30 mL), and the organic layer was dried (MgSO₄). Evaporation of the solvent and flash chromatography of the residue over silica gel (50 x 200 mm) using 10% ethyl acetate--hexane gave 199 (2.44 g, 99%) as a colorless oil: 1 H NMR (CDCl₃, 300 MHz) δ 0.14 (s) and 0.19 (s) [both signals together correspond to 6 H], 0.97 (s, 9 H), 2.58--2.79 (m, 2 H), 4.15--4.27 [m, including a d (J = 4.8 Hz) at δ 4.19, 3 H], 4.57 (s, 2 H), 6.45 (dt, J = 5.2 Hz, 1 H), 7.30--7.42 (m, 5 H).

(Z)-3-[[Dimethyl(1,1-dimethylethyl)silyl]oxy]-6-hydroxy-4-iodo-4-hexenenitrile (200).

Boron tribromide (1 M in CH₂Cl₂, 550 mL, 0.55 mmol) was added over

1 min to a cold (-78 °C) stirred solution of **199** (238 mg, 0.52 mmol) in dry dichloromethane (5 mL). Stirring at 0 °C was continued for 45 min and the mixture was then quenched with saturated aqueous sodium bicarbonate (1 \times 5 mL). The mixture was diluted with ether (1 \times 15 mL), and the organic layer was washed with water (1 \times 5 mL), and dried (MgSO₄). Evaporation of the solvent and flash chromatography of the residue over silica gel (15 \times 200 mm) using 35% ethyl acetate--hexane gave **200** (176 mg, 92%) as a white solid: ¹H NMR (CDCl₃, 300 MHz) δ 0.12 (s) and 0.19 (s) [both signals together correspond to 6 H], 0.97 (s, 9 H), 1.74 (t, J = 5.6 Hz, 1 H), 2.70 (d, J = 6.0 Hz, 2 H), 4.22 (t, J = 6.0 Hz, 2 H), 4.31 (t, J = 5.6 Hz, 2 H), 6.45 (dt, J = 6.0, 0.8 Hz, 1 H).

(Z)-5-[[5-Cyano-4-[[dimethyl(1,1-dimethylethyl)silyl]oxy]-3-iodo-2-pentenyl]oxy]-2(5H)furanone (193).

(a) Silver triflate (806 mg, 3.14 mmol) in dry nitromethane (15 mL) and 2,4,6-collidine (0.389 mL, 2.94 mmol) in dry nitromethane (15 mL) were added simultaneously over 1 h (syringe pump) to a cold (0 °C) and stirred solution of 200 (807 mg, 1.96 mmol) and 5-bromo-2(5H)-furanone⁴⁹ 221 (476 mg, 2.94 mmol) in the same solvent (30 mL). The cold bath was removed and the mixture was stirred for 1 h, and then diluted with ether (150 mL). The resulting mixture was washed with water (2 x 40 mL), and the organic layer was dried (MgSO₄). Evaporation of the solvent and flash chromatography of

the residue over silica gel ($50 \times 200 \text{ mm}$) using 35% ethyl acetate--hexane gave a 1:1 mixture of 200 and 193 (760 mg) which was used directly in the next experiment.

(b) tert-Butoxychlorodiphenylsilane⁶³ (0.542 mL, 2.03 mmol) and then DMAP (25 mg) were added to a stirred solution of 200 and 193 (760 mg) and triethylamine (0.281 g, 0.387 mL, 2.77 mmol) in dry dichloromethane (20 mL). Stirring at room temperature was continued for 1 h and the mixture was diluted with dichloromethane (30 mL). The resulting mixture was washed with saturated aqueous sodium bicarbonate (1 x 10 mL), water (1 x 10 mL), and dried (MgSO₄). Evaporation of the solvent and flash chromatography of the residue over silica gel (25 x 200 mm) using 6% ethyl acetate--hexane gave pure 193 (438 mg, 50%) and the silyl ether derivative of 200 (323 mg, 24 %). Compound 193 had: FT-IR (CHCl₃ cast) 2240, 1798, 1782 cm⁻¹; ¹H NMR (CDCl₃, 300 MHz) δ 0.10 (s) and 0.15 (s) [both signals together correspond to 6 H), 0.92 (s, 9 H), 2.6--2.78 (m, 2 H), 4.18--4.28 (m, 1 H), 4.30--4.50 (m, 2 H), 5.96--6.00 (m, 1 H), 6.26 (dt, J = 6.0, 1.0 Hz, 1 H), 6.39--6.47 (m, 1 H), 7.24 (dt, J = 5.6, 1.5 Hz, 1 H); 13C NMR (CDCl₃, 75.5 MHz) δ -5.13, -4.64, 17.97, 25.54, 26.98, 27.01, 72.69, 72.79, 74.82, 102.42, 102.47, 111.57, 111.94, 116.30, 116.35, 125.14, 125.17, 133.07, 133.20, 150.05, 170.00; exact mass, m/z calcd for $C_{15}H_{21}INO_4Si$ (M - CH_3)+ 434.0284, found 434.0276.

3-[[Dimethyl(1,1-dimethylethyl)silyl]oxy]-3-[2,3,3a,7a-tetrahydro-2-oxo-6*H*-furo[2,3-b]pyran-4-yl]propanenitrile (202a and 202b).

193 202a and 202b

Tributyltin hydride (22 mg, 0.076 mmol) in dry benzene (0.5 mL) and AIBN (2 mg, 0.01 mmol) in benzene (0.5 mL) were added simultaneously over 12 h (syringe pump) to a refluxing solution of **193** (24 mg, 0.05 mmol) in dry benzene (1.5 mL). After the end of the addition, the mixture was refluxed for an arbitrary period of 4 h, cooled and evaporated. Flash chromatography of the residue over silica gel (10 x 120 mm) using 35% ethyl acetate--hexane gave **202a** and **202b** (5 mg, 28%) as an oil: FT-IR (CHCl₃ cast) 2260, 1792 cm⁻¹; ¹H NMR (CDCl₃, 200 MHz) (1:1 mixture of isomers) δ 0.09 (s), 0.10 (s), 0.17 (s), and 0.18 (s) [all signals together correspond to 6 H], 0.92 (s, 9 H), 2.42--2.92 (m, 4 H), 2.92--3.10 (m, 1 H), 4.20--4.55 (m, 3 or 4 H), 5.72 (s, 0.5 H), 5.73 (s, 0.5H), 5.99 (t, J = 3.0 Hz, 0.5 H), 6.12 (t, J = 2.4 Hz, 0.5 H); exact mass, m/z calcd for $C_{12}H_{16}NO_4Si$ (M - C_4H_9)+ 266.0849, found 266.0847.

The use of triphenyltin hydride, higher temperature (refluxing toluene) or the use of triethylborane/air did not lead to any significant improvements. In one experiment, a small amount of tert-butyldimethylsilyloxy-3-hex-4-enenitrile 204 (19%) was isolated (see page XX).

(2-Chloroethyl) 3-Oxo-6-heptenoate (234).

A solution of methyl-3-oxohept-6-enoate⁵⁴ (30.0 g, 0.436 mol) and titanium tetraisopropoxide (5 ml, 17 mmol) in 2-chloroethanol (750 mL) was stirred at 55 °C for 16 h and then at 75 °C for 24 h. The solvent was distilled

off through a short Vigreux column under high vacuum (temperature < 70 °C) and the residue was partially purified by flash chromatography over silica gel (100 x 180 mm) using 10--20% ethyl acetate--hexane to afford impure 234 (40 g) as a reddish oil which was contaminated by some starting material and solvent. Removal of the solvent as above and Kugelrohr distillation of the residue (120--130 °C, 0.4 mm) gave 234 (26.0 g, 66%) as a colorless oil, contaminated by *ca* 10 mol% (by ¹H NMR) of some starting material: FT-IR (CHCl₃ cast) 1749, 1717, 1640 cm⁻¹; ¹H NMR (CDCl₃, 200 MHz) δ 2.32--2.40 (m, 2 H), 2.68 (t, J = 7.2 Hz, 2 H), 3.52 (s, 2 H), 3.60 (t, J = 6.4 Hz, 2 H), 4.40 (t, J = 6.4 Hz, 2 H), 4.98-5.09 (dm, J = 10.4 Hz, 1 H), 5.03--5.09 (dm, J = 16.8 Hz, 1 H), 5.81 (ddt, J = 16.8 Hz, 10.4 Hz, 6.4 Hz, 1 H); exact mass, *m*/z calcd for C₉H₁₃³⁵ClO₃ 204.0553, found 204.0553.

1-(1,3-Dioxolan-2-ylidene)-5-hexen-2-one (235).55

Dry # and powdered (325 mesh) potassium carbonate (Aldrich, 22.35 g) was added to a stirred solution of 234 (27.86 g, 0.136 mol) in dry DMF (105 mL). The mixture was stirred for 15 h and diluted with dry ether (350 mL, from a freshly opened can). The solids were allowed to settle and the solution was transferred under argon to a dry 1-L round-bottomed flask through a pad of Florisil#(120 x 35 mm).

[#] Potassium carbonate and Florisil were dried overnight at 80 °C under oil pump vacuum.

The same operation was repeated twice more with dry ether (2 x 150 mL) and the combined solvents were evaporated under water pump vacuum (protection from moisture). Kugelrohr distillation of the residue (85 °C, 0.01 mm) removed most of the DMF, leaving the crude ketene acetal 235 which was transferred (under argon) to a smaller flask. Kugelrohr distillation (105-135 °C, 0.01 mm) afforded 235 (19.88 g, 87%) as a colorless oil which solidifies when kept in a refrigerator: FT-IR (CHCl₃ cast) 1715, 1673, 1620, 1585, 1041 cm⁻¹; ¹H NMR (CDCl₃, 200 MHz) δ 2.25--2.37 (m, 2 H), 2.42--2.52 (m, 2 H), 4.33--4.41 (m, 2 H), 4.51--4.62 (m, 2H), 4.88--5.05 (m, including s at δ 4.93, 3 H), 5.77 (ddt, J = 17.2, 10.1, 6.5 Hz, 1 H); ¹³C NMR (CDCl₃, 100.6 MHz) δ 28.83, 41.45, 65.40, 68.16, 78.38, 114.41, 137.76, 168.32, 196.4; exact mass, m/z calcd for C9H₁₂O₃ 168.0787, found 168.0785.

[1-(1,3-Dioxolan-2-ylidene)-2,5-hexadien-2-yl)oxy]trimethylsilane (218).

A solution of ketene acetal 235 (19.0 g, 113 mmol) in dry THF (100 mL) was added over 1 h to a cold (-78 °C) and stirred solution of lithium bis(dimethylphenylsilyl)amide ^{56,#} in dry THF (700 mL). The mixture was stirred for 10 min after the addition was complete and then chlorotrimethylsilane (18.46 g, 21.65 mL, 170 mmol) was added.

[#] Prepared by treatment of a cold (0 °C) and stirred solution of bis(dimethylphenylsilyl)amine 64 (39.33 g, 0.138 mol) in dry THF (700 mL) with n-butyllithium (1.6 M in hexanes, 78.8 mL, 0.126 mol) followed by stirring for 20 min.at 0 °C

The cold bath was removed and the solution was allowed to warm to room temperature. The solvents were evaporated under water pump vacuum (protection from moisture). The residue was diluted with dry pentane (400 mL) and the solids were allowed to settle. The solution was transferred via cannula (under argon) to a dry 1-L round-bottomed flask through a pad of Florisil## (20 x 25 mm). Dilution with pentane (150 mL) and filtration through Florisil was repeated once more and the combined solvents were evaporated (protection from moisture). Kugelrohr distillation of the residue (115-125 °C, 0.12 mm) afforded 218 as a solution (ca 40% w/w) in bis(dimethyl)phenylsilylamine (65.82 g, ca 100%): FT-IR (CHCl₃ cast) cm⁻¹; ¹H NMR (CDCl₃, 400 MHz) (signals corresponding to 218 only) δ 2.8--2.92 (m, 2 H), 4.14--4.24 (m, 2 H), 4.28--4.40 (m, 2 H), 4.76 (t, J = 7.2 Hz, 1 H), 4.92--5.01 (dm, J = 10.0 Hz, 1 H), 5.07 (ddd, J = 17.2, 3.9, 1.9 Hz, 1 H), 5.87 (ddt, J = 17.2, 10.0, 6.2 Hz, 1 H); ¹³C NMR (CDCl₃, 75.5 MHz) δ ; exact mass, m/z calcd for C₁₉H₂₂O₂ 282.1618, found 282.1620.

Methyl $(6\alpha,7\beta,8\beta)$ - and $(6\alpha,7\beta,8\alpha)$ -6-Nitro-9-oxo-8-(2-propenyl)-1,4-dioxaspiro[4,5]decan-7-carboxylate (237a and 237b).

Dried overnight at 80 °C under oil pump vaccuum

A solution of (Z)-methyl-3-nitropropenoate⁶⁵ (12.38 g, 94 mmol) in dry THF (15 mL plus 5 mL as a rinse) was added dropwise over 3 min to a cold (0 °C) and stirred solution of freshly prepared (1 hour old) diene 218 (ca 40% w/w in bis(dimethylphenylsilyl)amine; 65.82 g, ca 113 mmol) diluted with dry THF (10 mL). The mixture was stirred at 0 °C for 50 min and then aqueous hydrochloric acid 0.005 M (70 mL) in THF (300 mL) was added. The mixture was stirred for 1 h at 0 to 15°C and diluted with ether (1200 mL). The organic layer was separated and washed with water (3 x 100 mL), and dried (MgSO₄). Evaporation of the solvent and flash chromatography of the residue over silica gel (10 x 20 cm) using 30--40% ethyl acetate--hexane afforded slightly impure material as a oil. This was allowed to crystallize and was then washed with a small amount of ether (in order to remove the liquid impurities present) to afford 237a and 237b (18.11 g, 64%) in a ratio of 83:17 [¹H NMR (400 MHz)] as a white solid. Carefull cristallization afforded pure 237a, the mother liquor being enriched in 237b. Compound 237a had: FT-IR (CHCl₃ cast) 1732, 1559 cm⁻¹; ¹H NMR (CDCl₃, 400 MHz) δ 2.12--2.20 (m, 1 H), 2.33--2.42 (m, 1 H), 2.56 (d, J = 8.0 Hz, 1 H), 2.78 (d, J = 8.0 Hz, 1 H), 2.96--3.05 (m, 1 H), 3.70 (s, 3 H), 3.83 (dd, J = 10.0, 5.0 Hz, 1 H), 3.86--4.03 (m, 4 H), 5.00--5.05 (dm, J = 8.0 Hz, 2 H),5.33 (d, J = 10.0 Hz, 1 H), 5.52--5.63 (m, 1 H); 13 C NMR (CDCl₃, 100.6 MHz) δ 32.02, 44.46, 47.99, 48.66, 52.68, 65.76, 65.83, 85.04, 107.11, 118.11, 133.25, 169.60, 202.38; exact mass, m/z calcd for C₁₃H₁₇NO₇ 299.1005, found 299.1001. Anal. Calcd for C₁₃H₁₇NO₇: C, 52.14; H, 5.73, N, 4.68. Found: C, 52.04; H, 5.70, N, 4.64. The sample enriched in the minor isomer 237b had: ¹H NMR (CDCl₃, 400 MHz) (most significant signals only) δ 3.55 (dd, J = 10.4, 9.6 Hz, 1 H), 3.71 (s, 3 H), 5.05--5.10 (dm, 12.0 Hz, 2 H), 5.30 (d, J = 10.0 Hz, 1 H), 5.65--5.75 (m, 1 H); 13 C NMR (CDCl₃, 100.6 MHz) δ 30.81, 46.14, 49.09, 50.42, 52.90, 65.88, 88.42, 106.93, 118.33, 133.78, 171.16, 200.88.

When the same reaction was performed under similar conditions using (Z)-3-nitropropenoate (317 mg, 2.42 mmol) and diene 218 (ca 40% w/w in disilylamine; ca 3.39 mmol), the yield of 237a and 237b was increased (606 mg, 84%). When the reaction was done at -10 °C, the ratio of isomers 237a vs 237b increased to 89:11 but the yield was similar.

 $(7\alpha,8\alpha,9\alpha,10\beta)$ - and $(7\alpha,8\beta,9\alpha,10\beta)$ -9-(Hydroxymethyl)-10-nitro-8-(2-propenyl)-1,4-di-oxaspiro[4,5]decan-7-ol (238a and 238b).

A solution of 237a and 237b (83:17, 308 mg, 1.03 mmol) in 2:1 toluenedichloromethane (26 mL) was added dropwise over 1 min to a cold (-10 °C) and stirred solution of diisobutylaluminum hydride (1 M in dichloromethane, 4.5 mL, 4.5 mmol) in dry dichloromethane (20 mL). The mixture was stirred at -10 °C for 15 min and then quenched by careful addition of methanol (1 mL). The cooling bath was removed, and Celite and of sodium sulfate decahydrate were added in one portion. The resulting suspension was stirred vigorously for 15 min and then the solids were filtered off through a short pad (40 x 60 mm) of Celite and washed with dichloromethane. The combined solvents were dried (MgSO₄) and evaporated. Flash chromatography of the residue over silica gel (25 x 150 mm) using 40--60% ethyl acetate--hexane afforded 238b (78 mg, 28 %) and the

chromatographically less mobile 238a (149 mg, 53 %), both as white solids#. The chromatographically more mobile 238b had: FT-IR (CHCl₃ cast) 3640-3100, 1561 cm⁻¹; ¹H NMR (CDCl₃, 300 MHz) δ 1.88--2.14 (m, 3 H), 2.21--2.47 (m, 2 H), 2.60 (broad t, J = 4.0 Hz, 1 H), 2.82--3.0 (m, 1 H), 3.60--3.82 (m, 2 H), 3.85-4.10 (m, 5 H), 4.83 (d, J = 9.2 Hz, 1 H), 5.0-5.15 (m, 2 H), 5.68--5.86 (m, 1 H); mass for C₁₂H₁₉NO₆ for C₁₂H₁₉NO₆ (chemical ionisation) 291 (M + 18)+. The chromatographically less mobile 238a had: FT-IR (CHCl₃ cast) 3600--3100, 1650 cm⁻¹; ¹H NMR (CDCl₃, 300 MHz) δ 1.91--2.05 (m, 2 H), 2.17--2.29 (m, 1 H), 2.32--2.52 (m, 3 H), 2.53--2.65 (m, 2 H), 3.78--3.88 (broad s, 2 H), 3.96--4.12 (m, 5 H), 4.95 (dd, J = 4.4, 1.0 Hz, 1 H), 5.19 (dm, J = 10.0 Hz, 1 H), 5.17 (dm, J = 16 Hz,1 H), 5.79--5.90 (m, 1 H); mass for C₁₂H₁₉NO₆ (chemical ionisation) 291 (M + 18)+.

 $(7\alpha,8\alpha,9\alpha,10\beta)$ -Dimethyl(1,1-dimethylethyl)-[[9-[[[dimethyl(1,1-dimethylethyl)silyl]oxy]methyl]-10-nitro-8-(2-propenyl)-1,4-dioxaspiro[4,5]decan-7-yl]oxy]silane (239).

Imidazole (814 mg, 11.97 mmol) and then tert-butylchlorodimethylsilane (818 mg, 5.42 mmol) were added to a stirred solution of 238a (369 mg, 1.36 mmol) in dry DMF (6 mL). The mixture was

[#] The yield is very dependent on the temperature of the reaction and on the order of addition of the reactants.

stirred at 50 °C overnight, poured into ether (60 mL), and washed with saturated aqueous sodium bicarbonate (10 mL). The organic layer was washed with water (10 mL) and dried (MgSO₄). Evaporation of the solvent and flash chromatography of the residue over silica gel (40 x 180 mm) using 4--6% ethyl acetate--hexane afforded 239 (619 mg, 91%) as a thick oil: With the exception of the signals attribuablee to the silicon substituents, the ¹H NMR spectra of 239 and 250 (from following experiment) are identical.

 $(7\alpha,8\alpha,9\alpha,10\beta)\text{-Dimethyl(1,1-dimethylethyl)-[[9-[[[triethylsilyl]oxy]-methyl]-10-nitro-8-(2-propenyl)-1,4-dioxaspiro[4,5]decan-7-yl]oxy]silane (250).$

Chlorotriethylsilane (0.852g, 0.950 mL, 5.66 mmol) and DMAP (a few crystals) were added in one portion to a stirred solution of 261 (1.90 g, 4.92 mmol) and triethylamine (0.746 g, 1.03 mL, 7.38 mmol) in dry dichloromethane (16 mL). Stirring was continued for 3 h at room temperature and the mixture was processed as described for 266. Flash chromatography of the residue on silica gel (50 x 180 mm) using 4--6% ethyl acetate--hexane afforded 250 (2.42 g, 98%) as a thick oil: FT-IR (CHCl₃ cast) 1552 cm⁻¹; ¹H NMR (CDCl₃, 200 MHz) δ 0.05 (s, 6 H) and 0.07 (s, 6 H), 0.57 (q, J = 8.0 Hz, 6 H), 0.84--1.0 (m, 18 H), 1.83 (dd, J = 14.3, 8.0 Hz, 1 H), 1.98--2.39 (m, 4 or 5

H), 2.46--2.61 (m, 1 H), 3.68 (dd, J = 10.0, 5.5 Hz, 1 H), 3.74--3.88 (m, 1 H), 3.90--4.09 (m, 6 H), 4.88 (d, J = 8.0 Hz, 1 H), 4.91--5.12 (m, 2 H), 5.72--5.98 (m, 1 H); 13 C NMR (CDCl₃, 106.6 MHz) δ -4.93, -4.57, 4.28, 6.73, 18.05, 25.77, 39.98, 42.68, 60.40, 64.93, 65.18, 69.41, 86.42, 106.85, 115.44, 138.26; exact mass, m/z calcd for C₂₄H₄₇NO₆Si₂ 501.2942, found 501.2940. Anal. Calcd for C₂₄H₄₇NO₆Si₂: C, 57.42; H, 9.44; N, 2.79. Found: C, 57.49; H, 9.29; N, 2.69.

 $(7\alpha,8\alpha,9\alpha,10\beta)-7-[[[Dimethyl(1,1-dimethylethyl)silyl]oxy]-9-[[[dimethyl-(1,1-dimethylethyl)silyl]oxy]methyl]-10-nitro-1,4-dioxaspiro[4,5]decan-8-yl]ethanal (243).$

(a) (7α,8α,9α,10β)-3-[7-[[Dimethyl(1,1-dimethylethyl)silyl]oxy]-9-[[[dimethyl(1,1-dimethylethyl)silyl]oxy]methyl]-10-nitro-1,4-dioxaspiro[4,5]decan-8-yl]propane-1,2-diol (241). Osmium tetroxide (2.5% w/v in tert-butanol, 4 mL, 0.3 mmol) was added to a stirred solution of 239 (3.0 g, 5.98 mmol) in acetone (30 mL) and water (12 mL). Stirring was continued for 15 min and then (N)-methylmorpholine-(N)-oxide monohydrate (970 mg, 7.2 mmol) was added in one portion. The mixture was stirred at room temperature for 6 h and diluted with ether (250 mL). The organic layer was washed with water (1 x 20 mL), 10% w/v aqueous sodium bisulfate (2 x 15 mL), and water (1 x 10 mL), and dried (MgSO₄). Evaporation of the solvent and flash

chromatography of the residue over silica gel (60 x 180 mm) using 50% ethyl acetate--hexane gave 242 (3.10 g, 96%) as a colorless oil.

(b) $(7\alpha,8\alpha,9\alpha,10\beta)$ -7-[[[Dimethyl(1,1-dimethylethyl)silyl]oxy]-9-[[[dimethyl(1,1-dimethylethyl)silyl]oxy]methyl]-10-nitro-1,4-dioxaspiro[4,5]decan-8-yl]ethanal (243). Sodium periodate (186 mg, 0.873 mmol) was added in one portion to a stirred solution of 242 (360 mg, 0.67 mmol) in methanol (8 mL). The suspension was stirred at room temperature for 2 h and the mixture was diluted with ether (60 mL), and washed with water (2 x 10 mL), and the organic layer was dried (MgSO₄). Evaporation of the solvent and flash chromatography of the residue over silica gel (60 x 180 mm) using 30% ethyl acetate--hexane gave 243 (290 mg, 85%) as a colorless oil: ¹H NMR (CDCl₃, 200 MHz) δ -0.02-0.12 [four s, 6 H], 0.85 (s, 9 H), 1.69 (dd, J = 13.5, 12.0 Hz, 1 H), 1.84 (ddd, J = 13.5, 4.5, 1.0 Hz, 1 H), 2.58--2.73 (m, 3 H), 2.96 (broad quintet, J = 5.5 Hz, 1 H), 3.64 (d, J = 4.1 Hz, 2 H), 3.84--4.12 [m, including a dt (J = 11.5, 4.8 Hz) at δ 4.06, 5 H], 4.75 (d, J = 12.0 Hz, 1 H), 9.74 (broad s, 1 H).

 $(7\alpha,8\alpha,9\alpha,10\beta)$ -[7-[[Dimethyl(1,1-dimethylethyl)silyl]oxy]-9-[[[dimethyl-(1,1-dimethylethyl)silyl]oxy]methyl]-10-nitro-1,4-dioxaspiro[4,5]decan-8-yl]-(phenylseleno)ethanal (245a and 245b).

Triethylamine (0.279 mL, 2 mmol), chlorotrimethylsilane (0.202 mL, 1.6

mmol) and then dry zinc chloride (*ca* 10 mg) were added to a stirred solution of 243 (100 mg, 0.2 mmol) in dry toluene (3 mL). The mixture was stirred at 80 °C for 4 h, allowed to cool to room temperature, and then cooled to -20 °C. Benzeneselenyl chloride (305 mg, 1.6 mmol) in dry dichloromethane (2 mL) was added over 30 sec to the resulting cold and stirred mixture of silylenolethers. The cooling bath was removed and the mixture was allowed to reach room temperature. The mixture was diluted with dichloromethane (25 mL) and washed with saturated aqueous sodium bicarbonate (2 x 5 mL) and water (5 mL), and dried (MgSO₄). Evaporation of the solvent and flash chromatography of the residue over silica gel (20 x 180 mm) using 30% ethyl acetate--hexane gave 245a and 245b (120 mg, 92 %) in a ratio [¹H NMR (200 MHz)] of 4:1. Compound 245a had: ¹H NMR (CDCl₃, 200 MHz) (most characteristic signals of the major compound only) δ 5.30 (broad s, 1 H), 9.52 (d, J = 3.0 Hz, 1 H).

In a different run, the Z/E mixture of silyl enol ethers 244a and 244b (8:1 ratio) was isolated (saturated aqueous sodium bicarbonate work-up) and a small amount of pure (Z)-silylenolether 244a could be recovered after flash chromatography. Treatment of this material with PhSeCl as above gave 245a and 245b in a 1:8 ratio [1 H NMR (200 MHz)] respectively, leading to the conclusion that the (Z) enolether 244a affords mainly 245b whereas the (E)-enol ether 244b gives mainly 245a...The (Z)-enol ether 244a had: 1 H NMR (CDCl₃, 200 MHz) δ 0.87 (s) and 0.88 (s) [both signals together correspond to 18 H], 1.85 (d, J = 4.0 Hz, 2 H), 2.57--2.73 (m, 1 H), 3.37--3.49 (m, 1 H), 3.55 (dd, J = 10.4, 6.0 Hz, 1 H), 3.85--4.10 (m, 5 H), 4.35 (dd, J = 11.0, 6.0 Hz, 1 H), 4.73 (d, J = 11.5 Hz, 1 H), 6.40 (d, J = 6.5 Hz, 1 H). The (E)-enol ether 244b had: 1 H NMR (CDCl₃, 200 MHz) δ 0.88 (s, 18 H), 1.75--1.88 (m, 2 H), 2.52--2.80 (m, 2 H), 3.41 (dd, J = 9.6, 9.2 Hz, 1 H), 3.81-4.08 (m, 5 H), 4.59 (d, J = 12.0 Hz, 1 H), 4.81 (dd, J =

11.2, 11.0 Hz, 1 H), 6.28 (d, J = 12.0 Hz, 1 H). The seleno aldehyde 245b had: 1 H NMR (CDCl₃, 200 MHz) δ 0.00--0.25 [4 x (s), 12 H], 0.89 (s, 9 H), 0.97 (s, 9 H), 2.10-2.95 (m, 4 H), 3.68 (dd, J = 11.2, 4.8 Hz, 1 H), 3.85--4.39 (m, 6 H), 4.65--4.79 (m, 1 H), 5.09 (broad d, J = 3.2 Hz, 1 H), 7.27--7.75 (m, 5 H), 9.40 (d, J = 4.8 Hz, 1 H).

Methyl $(6\alpha,7\beta,8\beta,9\beta)$ -[9-[[Dimethyl(1,1-dimethylethyl)silyl]oxy]-7-[[[triethylsilyl]oxy]-methyl]-8-(2-oxoethyl)-1,4-dioxaspiro[4,5]decan-6-yl]carbamate (253).

- (a) $(7\alpha,8\alpha,9\alpha,10\beta)$ -3-[7-[[Dimethyl(1,1-dimethylethyl)silyl]oxy]-9-[[[triethylsilyl]oxy]methyl]-10-nitro-1,4-dioxaspiro[4,5]decan-8-yl]propane-1,2diol (251). The diol 251 (R = Et₃Si) was prepared in 95% yield using osmium tetroxide and N-methylmorpholine-N-oxide in aqueous acetone as described for the conversion of 239 to 242.
- (b) Methyl $(6\alpha,7\beta,8\beta,9\beta)$ -[9-[[Dimethyl(1,1-dimethylethyl)silyl]oxy]-7-[[[triethylsilyl]oxy]-methyl]-8-(2,3-dihydropropyl)-1,4-dioxaspiro[4,5]decan-6-yl]carbamate (252).Treatment of 251 (R = Et₃Si) (382 mg, 0.71 mmol) in 2:1

ethanol--methanol (12 mL) with Raney Nickel# (grade T-166, ca 1.46 g) as --described for the conversion of 266 to 267, gave the corresponding crude amine (300 mg). This amine was dissolved in dry dichloromethane (10 mL) and the solution was cooled to -45 °C. Triethylamine (0.172 mL, 1.20 mmol) and methyl chloroformate (68 μ L, 0.87 mmol) were added to this cold and stirred solution. The mixture was stirred at -45 to -20 °C for 15 min and was then quenched by addition of saturated aqueous sodium bicarbonate (1 x 5 mL). The mixture was diluted with ether (30 mL) and the organic layer was washed with water (1 x 5 mL), and dried (MgSO₄). Evaporation of the solvent and flash chromatography of the residue over silica gel (20 x 180 mm) using 70% ethyl acetate--hexane gave 252 (R = Et₃Si) (176 mg, 44% from 251) as a colorless oil.

(c) Methyl $(6\alpha,7\beta,8\beta,9\beta)$ -[9-[[Dimethyl(1,1-dimethylethyl)silyl]oxy]-7- [[[triethylsilyl]oxy]-methyl]-8-(2-oxoethyl)-1,4-dioxaspiro[4,5]decan-6-yl]-carbamate (253). Treatment of 252 (R = Et₃Si) (44 mg, 0.078 mmol) with sodium periodate (45 mg, 0.21 mmol) as described for the conversion of 242 to 243 gave 253 (R = Et₃Si) (27 mg, 65%)##: 1 H NMR (CDCl₃, 200 MHz) [The signals are either broadened or doubled due to the presence of rotational isomers (see discussion)] δ 0.05 (s) and 0.07 (s) [both signals together correspond to 6 H], 0.55 (q, J = 8.0 Hz, 6 H), 0.83 (s, 9 H), 0.92 (t, J = 8.0 Hz, 9 H), 1.55-1.95 (m, 4 H), 2.35 (broad dd, J = 16.0, 4.8 Hz, 1 H), 2.58 (ddd, J = 16.0, 7.0, 2.5 Hz, 1 H), 2.80-2.95 (m, 1 H), 3.52 (dd, J = 10.2, 8.8 Hz, 1 H), 3.58-3.79 (m, -----

[#] The procedure for the preparation of the Raney Nickel described by Dominguez et al. 66 was followed, but with some important modifications. Care was taken to remove all traces of base on the catalyst by washing it thoroughly with water (3 times), 0.005 M aqueous acetic acid (3 times), water (3 times or until pH = 7), and absolute ethanol (5 times). The catalyst was kept under ethanol at 0 °C.

^{##} The corresponding bis(tert-butyldimethylsilyl) derivative 253 (R = t-BuMe₂Si) was obtained from 250 (R = t-BuMe₂Si) in similar yield (40% overall) using the same procedure.

including s at δ 3.65, 4 H), 3.80--4.11 (m, 5 H), 4.40 (broad d, J = 10.0 Hz, 0.25 H) and 4.60 (broad d, J = 10.0 Hz, 0.75 H), 9.65 (broad s, 1 H).

Methyl $(6\alpha,7\beta,8\beta,9\beta)$ -[9-[[Dimethyl(1,1-dimethylethyl)silyl]oxy]-7-[[[triethylsilyl]oxy]methyl]-8-[2-oxo-1-(phenylseleno)ethyl]-1,4-dioxaspiro[4,5]decan-6-yl]carbamate (254a and 254b)

Treatment of 253 (R = Et₃Si) with triethyl-amine/chlorotrimethylsilane and benzeneselenyl chloride as described for the conversion of 243 to 245a and 245b (70%) gave 254a and 254b (R = Et₃Si) in a ratio [1 H NMR (200 MHz)] of 3:1: 1 H NMR (CDCl₃, 200 MHz) (Most characteristic peaks only) δ 9.17 (broad d, J = 8.0 Hz, 0.25 H), 9.25--9.40 (broad s, 0.75 H).

Using the same procedure, 254a and 254b ($R = t\text{-BuMe}_2\text{Si}$) were obtained from 253 ($R = t\text{-BuMe}_2\text{Si}$) in similar yield but the ratio of isomers was 5.3:1 instead of 3:1. ¹H NMR (CDCl₃, 200 MHz) (most characteristic peaks only) δ 9.18 (broad d, J = 8.4 Hz, 0.16 H), 9.25--9.40 (broad s, 0.86 H).

Methyl (*Z*)- and (*E*)-(6α , 7β , 9β)-[9-[[Dimethyl(1,1-dimethylethyl)silyl]-oxy]-7-[[[triethylsilyl]oxy]-methyl]-8-(2-oxoethylidene)-1,4-dioxaspiro[4,5]decan-6-yl]carbamate (255a and 255b).

Pyridine (26 µl, 0.33 mmol) and 30% aqueous hydrogen peroxide (18 µl, 0.17 mmol) were added to a stirred solution of 254a and 254b (R = Et₃Si) (3:1, 19 mg, 0.028 mmol) in dichloromethane (1 mL) and THF (0.2 mL). The mixture was stirred at room temperature for 16 h and then diluted with dichloromethane (10 mL). The resulting mixture was washed with saturated aqueous sodium bicarbonate (1 x 3 mL), 10% aqueous copper sulfate (1 x 3 mL), 10% w/v aqueous sodium bisulfite (1 x 3 mL), and water (1 x 3 mL), and dried (MgSO₄). Evaporation of the solvent and flash chromatography of the residue over silica gel (10 x 150 mm) using 30% ethyl acetate--hexane gave 255a and 255b (R = Et₃Si) (5.5 mg, 37%) as a 2.1:1 mixture of isomers: ¹H NMR (CDCl₃, 400 MHz) (most characteristic signals only) δ 4.25–4.40 (m, ω 0.3 H), 4.71--4.82 (m, ω 0.7 H), 5.95 (d, J = 8.0 Hz, 1 H), 9.90 (d, J = 8.0 Hz, 0.3 H), 10.55

(broad d, J = 8.0 Hz, 0.7 H).

Using the same procedure, 255a and 255b (R = t-BuMe₂Si) were obtained from 254a and 254b (R = t-BuMe₂Si) in similar yield but the ratio of isomers was 5.3:1 instead of 3:1.

Methyl (Z)-(6 α ,7 β ,9 β)-[9-[[Dimethyl(1,1-dimethylethyl)silyl]oxyl-7-(hydroxymethyl)-8-(2-oxoethylidene)-1,4-dioxaspiro[4,5]decan-6-yl]carbamate (257) and Methyl (5 α ,8 β ,8a β)-5-[[Dimethyl(1,1-dimethylethyl)silyl]oxyl-7,7-(ethylenedioxy)-3,5,6,7,8,8a-hexahydro-3-hydroxy-1H-2-benzopyran-8-yl)carbamate (256).

Trifluoroacetic acid (2.1 μ l, 0.028 mmol) was added to a cold (0 °C) and stirred solution of 255a and 255b (7:3, 5.0 mg, 0.0094 mmol) in 3:1 THF--water (0.65 mL). The mixture was stirred at 0 °C for 1 h and diluted with dichloromethane (10 mL). The mixture was washed with saturated aqueous sodium bicarbonate (2 mL), and water (2 mL), and dried (MgSO₄).

Evaporation of the solvent and flash chromatography of the residue over silica gel (5 x 60 mm) using 75% ethyl acetate--hexane gave 257 and 256 in a 7:3 (¹H NMR) ratio. Compound 257 had: ¹H NMR (CDCl₃, 400 MHz) δ 1.93 (dd, J = 13.0, 11.0 Hz, 0.71 H), 2.22 (dd, J = 13.0, 5.0 Hz, 0.71 H), 4.60 (dd. J = 11.6, 5.0 Hz, 0.71 H), 6.3 (d, J = 7.2 Hz, 0.71 H), 10.69 (d, J = 7.2 Hz, 0.71 H). No other signals for an aldehyde were present; instead signals corresponding to the presumed lactol(s) 256 were observed. Compound(s) 256 had ¹H NMR (CDCl₃, 400 MHz) δ 4.68--4.75 (m, 0.29 H), 5.38--5.47 (m, 0.29 H), 5.90--5.95 (m, 0.29 H).

Methyl $(6\alpha,7\beta)$ -[9-Hydroxy-6-nitro-8-(2-propenyl)-1,4-dioxaspiro[4,5]decan-7-yl]carboxylate (259).

Sodium borohydride (6.0 g, 157.0 mmol) was added in one portion to a cold (-78 °C) and stirred solution of 237a and 237b (83:17, 9.02 g, 30.2 mmol) in 1:5 dichloromethane--methanol. The mixture was allowed to reach room temperature over 2 h, and was then quenched by addition of saturated aqueous ammonium chloride (30 mL) Most of the solvents were evaporated and the residue was extracted with ethyl acetate (3 x 200 mL). The combined organic extracts were washed with water (50 mL), and brine (50 mL), and dried (MgSO4). Evaporation of the solvent and flash chromatography of the residual oil over silica gel (50 x 200 mm) using 50--60% ethyl acetate--hexane

afforded 259 as a mixture of three isomeric alcohols (8.78 g, 97%).

Methyl $(6\alpha,7\beta,8\alpha,9\alpha)$ -[9-[[Dimethyl(1,1-dimethylethyl)silyl]oxy]-6-nitro-8-(2-propenyl)-1,4-dioxaspiro[4,5]decan-7-yl]carboxylate (260).

Dry lutidine (6.17 g, 6.7 mL, 57.67 mmol) was injected into a stirred solution of 259 (8.68 g, 28.83 mmol) in dry dichloromethane (50 mL) kept at Immediatly thereafter, tertroom temperature by a water bath. butyldimethylsilyl triflate (11.43g, 9.94 mL, 43.24 mmol) was injected, the bath was removed, and the mixture was stirred for 1 h. The mixture was diluted with ether (250 mL) and washed (slow addition at first) with 10% w/v aqueous copper sulfate (75 mL). The aqueous layer was extracted with ether (250 mL) and the combined extracts were washed with 10% w/v aqueous copper sulfate (75 mL), water (75 mL), and brine (75 mL), and dried (MgSO₄). Evaporation of the solvent and flash chromatography of the residue over silica gel (120 x 180 mm) using 5--10% ethyl acetate--hexane gave 260 (7.5 g, 63%) and a 1:1 mixture of 2 isomeric silyl ethers 260' (3.05g, 25%). Coumpound 260 had: FT-IR (CHCl₃ cast) 1740, 1560 cm⁻¹; ¹H NMR (CDCl₃, 400 MHz) δ 0.08 (s, 6 H), 0.89 (s, 9 H), 1.77 (d, J = 8.2 Hz) and 1.85 (dt, J = 14.5, 8.0 Hz) [both signals together correspond to 3 H], 2.37--2.48 (m, 1 H), 2.50--2.65 (dm, J = 14.5 Hz, 1 H), 3.52 (dd, J = 12.0, 4.5 Hz, 1 H), 3.62 (s, 3 H), 3.87 - 4.14 [m, including] a dt (J = 8.0, 5.0 Hz) at δ 4.06, 5 H], 4.87--5.00 [m, including d (J = 12.0 Hz) at δ 4.97, 3 H], 5.49--5.71 (m, 1 H); ¹³C NMR (CDCl₃, 106.6 MHz) δ -4.75, -4.78, 18.04, 25.74, 27.11, 40.48, 42.66, 45.01, 51.99, 65.34, 65.59, 68.83, 84.87, 107.57, 115.90, 137.12, 170.76; exact mass, m/z calcd for C₁₉H₃₃NO₇Si 415.2027, found 415.2040.

 $(6\alpha,7\beta,8\beta,9\beta)$ -[9-[[Dimethyl(1,1-uimethylethyl)silyl]oxy]-6-nitro-8-(2-propenyl)-1,4-dioxaspiro[4,5]decan-7-yl]methanol (261).

A solution of 260 (2.78 g, 6.68 mmol) in dry dichloromethane (30 mL + 5 mL as a rinse) was added by cannula over 4 min to a cold (-30 °C) and stirred solution of diisobutylaluminium hydride (1 M in dichloromethane, 20 mL, 20 mmol) in dry dichloromethane (140 mL). The mixture was stirred for 15 min and quenched by careful addition of methanol (10 mL). The bath was removed and a large amount of Celite and sodium sulfate decahydrate (*ca* 50 g) were added. The mixture was then stirred for 15 min and the solids were filtered off through a pad of Celite (70 x 90 mm) and washed with dichloromethane. The solvent was dried (MgSO₄) and evaporated. Flash chromatography of the residue over silica gel (25 x 180 mm) using 20% ethyl acetate--hexane afforded 261 (2.27 g, 87%) as a thick, colorless oil: FT-IR (CHCl₃ cast) 3650-3100, 1640, 1553 cm⁻¹; ¹H NMR (CDCl₃, 200 MHz) δ 0.07 (s, 6 H), 1.70-1.86 (m, 2 H), 1.92--2.16 (m, 2 H), 2.25--2.39 (m, 1 H), 2.40--2.56 (m, 1 H), 2.63 (s,

J = 5.3 Hz, 1 H), 3.64–3.80 (m, 2 H), 3.95 (s, 4 H), 4.04 (dt, J = 8.7, 3.8 Hz, 1 H), 4.82 (d, J = 9.5 Hz, 1 H), 5.02–5.20 (m, 2 H), 5.75–6.00 (m, 1 H); 13 C NMR (CDCl₃, 100.6 MHz) δ -4.89, -4.63, 17.99, 25.72, 40.37, 42.01, 60.09, 65.16, 65.82, 69.09, 86.68, 107.09, 115.91, 138.65; exact mass, m/z calcd for C₁₈H₃₃NO₆Si 387.2077, found 387.2074. Anal. Calcd for C₁₈H₃₃NO₆Si: C, 55.78; H, 8.58; N, 3.61. Found: C, 56.12; H, 8.76; N, 3.79.

 $(4a\alpha,5\beta,8\alpha,8a\alpha)-5-[[Dimethyl(1,1-dimethylethyl)silyl]oxy]-7,7-\\ (ethylenedioxy)octahydro-3-hydroxy-8-nitro-1H-2-benzopyran (262a and 262b).$

OH

261

262a and 262b

Osmium tetroxide (2.5% w/v in *tert*-butanol, 4 mL) was added to a stirred solution of **261** (2.13 g, 5.5 mmol) in 2:2:1 carbon tetrachloride--water-*tert*-butanol (75 mL). The mixture was stirred for 15 min, and sodium periodate (2.93 g, 13.75 mmol) was added in one portion. After 3 h, the resulting suspension was diluted with water (20 mL) and extracted with ether (400 mL). The organic layer was washed with water (20 mL), 10% w/v aquous sodium bisulfite (20 mL), and water (20 mL), dried (MgSO₄), and evaporated. Flash chromatography of the residue over silica gel (60 x 180 mm) using 25-30% ethyl acetate--hexane gave **262a** and **262b** (2.10g, 98%) as a white solid consisting of a 3:1 mixture [¹H NMR (400 MHz)] of isomeric lactols: ¹H NMR (CDCl₃, 200 MHz) δ 0.04 (s) and 0.07 (s) [both signals together correspond to 6

H], 0.84 (s, 9 H), 1.16--1.38 (m, 0.25 H), 1.43--1.60 (m, 0.75 H), 1.72--1.85 (m, 2.7 H), 1.93--2.05 (m, 0.25 H), 2.18--2.35 (m, 0.25 H), 2.40--2.70 (m, 2.5 H), 3.20--3.30 (m, 0.75 H), 3.55--3.75 (m, 0.5 H), 3.85--4.02 (m, 4 H), 4.02--4.21 (m, 2 H), 4.67--4.78 (m, 0.25 H), 5.03 (d, J = 12.5 Hz) and 5.05 (d, J = 12.5 Hz) [both signals together correspond to 1 H), 5.40 (broad s, 0.75 H).

 $(3\alpha,4a\beta,5\alpha,8\beta,8a\beta)-5-[[Dimethyl(1,1-dimethylethyl)silyl]oxy]-7,7-\\ (ethylenedioxy)octahydro-8-nitro-3-[[triethylsilyl]oxy]-1H-2-benzopyran (266).$

Triethylamine (587 mg, 0.81 mL, 5.80 mmol), chlorotriethylsilane (700 mg, 0.78 mL, 4.66 mmol) and then N,N-(dimethylamino)pyridine (ca 100 mg) were added to a cold (0 °C) and stirred solution of **262a** and **262b** (1.51 g, 3.87 mmol) in dry dichloromethane (28 mL). The cold bath was removed and the mixture was stirred for 3 h. It was then diluted with ether (200 mL), washed with saturated aqueous sodium bicarbonate (30 mL), and 1:1 water--brine (30 mL), and dried (MgSO₄). Evaporation of the solvent and flash chromatography of the residue over silica gel (25 x 180 mm) using 6--8% ethyl acetate--hexane afforded **266** as a single isomer (1.88g, 96%) as a waxy solid: FT-IR (CHCl₃ cast) 1553, 1083 cm⁻¹; 1 H NMR (CDCl₃, 200 MHz) δ 0.06 (s, 6 H), 0.52--0.69 (m, 6 H), 0.85--1.00 (m including s at δ 0.89, 18 H), 1.26--1.43 (m, 1 H), 1.73--1.92 (m, 3 H), 2.23 (dq, J = 12.4 Hz, 4.8 Hz, 1 H), 2.37--2.50 (dm, J = 12.2 Hz, 1 H),

3.53 (dd, J = 13.0, 2.2 Hz, 1 H), 3.67 (d, J = 13.0 Hz, 1 H), 3.83--4.01 (m, 4 H), 4.02--4.16 (m, 1 H), 4.67 (dd, J = 9.0, 2.2 Hz, 1 H), 5.06 (d, J = 12.5 Hz, 1 H); 13 C NMR (CDCl₃, 100.6 MHz) δ -4.91, 4.82, 6.59, 17.87, 34.76, 39.22, 39.59, 65.02, 65.48, 65.69, 67.93, 85.52, 97.63, 108.08; exact mass, m/z calcd for C₂₃H₄₄NO₇Si₂ 502.2656, found 502.2670. Anal. Calcd for C₂₃H₄₄NO₇Si₂: C, 54.81; H, 9.01; N, 2.78. Found: C, 54.95; H, 8.90; N, 2.98.

 $(3\alpha,4a\beta,5\alpha,8\beta,8a\beta)$ -8-Amino-5-[[dimethyl(1,1-dimethylethyl)silyl]oxy]-7,7-(ethylenedioxy)octahydro-3-[[triethylsilyl]oxy]-1H-2-benzopyran (267).

A solution of 266 (1.85 g, 3.67 mmol) in ethyl acetate (4 mL + 1 mL as a rinse) was added to a suspension of Raney Nickel (grade T-1, ca 4.5 g)^{66,#} in 2:1 ethanol--methanol (70 mL) contained in a thick-wall 500-mL pyrex bottle. The mixture was shaken for 16 h on a Parr hydrogenator under hydrogen at 50 psi. The solvent was transferred by cannula (under argon) to a 500-mL round-bottomed flask through a pad of Celite (25 x 40 mm) and the catalyst was washed with ethyl acetate (40 ml) and dichloromethane (30 mL).

[#] The procedure for the preparation of the Raney Nickel described by Dominguez et al. 66 was followed, but with some important modifications. Care was taken to remove all traces of base on the catalyst by washing it thoroughly with water (3 times), 0.005 M aqueous acetic acid (3 times), water (3 times or until pH = 7), and absolute ethanol (5 times). The catalyst was kept under ethanol at 0 °C.

Evaporation of the combined solvents and flash chromatography of the residue over silica gel ($20 \times 60 \text{ mm}$) using first 50% ethyl acetate--hexane and then ethyl acetate gave **267** (1.55 g, 89%) as a waxy white solid: FT-IR (CHCl₃ cast) 3347 cm⁻¹; ¹H NMR (CDCl₃, 400 MHz) δ 0.03 (s, 6 H), 0.62 (q, J = 8.0 Hz, 6 H), 0.85 (s, 9 H), 0.95 (t, J = 8.0 Hz, 9 H), 1.0--1.18 (broad, ~ 2 H), 1.26 (broad d, J = 12.0 Hz, 1 H), 1.43 (dt, J = 14.0, 9.6 Hz, 1 H), 1.64 (t, J = 13.4 Hz, 1 H), 1.76--1.83 (dm, J = 13.6 Hz, 2 H), 2.06 (ddd, J = 13.6, 8.4, 4.0 Hz, 1 H), 3.08 (d, J = 11.6 Hz, 1 H), 3.41 (dd, J = 12.0, 2.2 Hz, 1 H), 3.94 (dt, J = 12.0, 5.0 Hz, 1 H), 3.98 (s, 4 H), 4.39 (d, J = 11.8 Hz, 1 H), 4.66 (broad d, J = 8.4 Hz, 1 H); ¹³C NMR (CDCl₃, 100.6 MHz) δ -4.80, 4.96, 6.73, 18.07, 25.78, 29.46, 38.23, 38.55, 40.22, 50.49, 65.07, 65.49, 66.17, 68.99, 97.88, 110.12; exact mass, m/z calcd for C₂₃H₄₇NO₅Si₂ 473.2993, found 473.2998. Anal. Calcd for C₂₃H₄₇NO₅Si₂: C, 58.28; H, 10.00; N, 2.96. Found: C, 58.32; H, 9.87; N, 2.98.

N-[(4a α ,5 β ,8 α ,8a α)-5-[[Dimethyl(1,1-dimethylethyl)silyl]oxy]-7,7-(ethylenedioxy)octahydro-3-oxo-1H-2-benzopyran-8-yl] trifluoroacetamide (269).

(a) N-[(3 α ,4 α ,5 α ,8 β ,8 α)-5-[[Dimethyl(1,1-dimethylethyl)silyl]oxy]-7,7-(ethylenedioxy)octahydro-3-[[triethylsilyl]oxy]-1H-2-benzopyran-8-yl] trifluoroacetamide (268). Trifluoroacetic anhydride (114 mg, 76 μ l, 0.542

mmol) was injected dropwise over 30 sec into a cold (- 30 °C) and stirred solution of 267 (171 mg, 0.361 mmol) and 4-(dimethylamino)pyridine (α 5 mg) in dry pyridine (0.9 mL). The mixture was stirred at -30 °C for 15 min, and 10% w/v aqueous copper sulfate (2 mL) and then ether (15 mL) were added. The organic layer was washed with 10% w/v aqueous copper sulfate (1 x 2 mL), and water (2 x 3 mL) and dried (MgSO₄). Evaporation of the solvent and flash chromatography of the residue over silica gel (15 x 150 mm) using 20-40% ethyl acetate--hexane afforded 268. A small amount (α 5-10 mol%) of the corresponding lactols 268' was also produced and this material was combined with 268 for the next step. Compound 268 had: FT-IR (CHCl₃ cast) 3300, 1712, 1560, 1081 cm⁻¹; ¹H NMR (CDCl₃, 400 MHz) δ 0.04 (s, 6 H), 0.57--0.67 (m, 6 H), 0.86 (s, 9 H), 0.90--0.99 (m, 9 H), 1.43--1.54 (m, 2 H), 1.73--1.89 (m, 3 H), 2.09--2.18 (dm, J = 13 Hz, 1 H), 3.45 (dd, J = 12.0, 2.4 Hz, 1 H), 3.76--3.88 (m, 2 H), 3.90--4.06 (m, 4 H), 4.53 (t, J = 10.8 Hz, 1 H), 4.67 (dd, J = 9.2, 2.4 Hz, 1 II), 5.98 (broad d, J = 10.0 Hz, 1 H).

(b) N-[($4a\alpha$,5 β ,8 α ,8 $a\alpha$)-5-[[Dimethyl(1,1-dimethylethyl)silyl]oxyl-7,7-(ethylenedioxy)octahydro-3-oxo-1H-2-benzopyran-8-yl] trifluoroacetamide (269). Celite (130 mg) and then pyridinium chlorochromate (230 mg, 1.06 mmol) were added to a stirred solution of 268 (194 mg, from above experiment) and 268' (15 mg) in dry dichloromethane (3.0 mL). The mixture was stirred at room temperature for 2 h and then at 35 °C for 4 h, and allowed to cool to room temperature. Flash chromatography of the mixture (no workup) over silica gel (20 x 150 mm) using 30% and then 50% ethyl acetate-hexane gave 269 (151 mg, 85% from amine 267) as a white solid: FT-IR (CHCl₃ cast) 3280, 1711 cm⁻¹; ¹H NMR (CDCl₃, 400 MHz) δ 0.09 (s, 6 H), 0.89 (s, 9 H), 1.85 (dd, J = 14.0, 9.8 Hz, 1 H), 1.94 (dd, J = 14.0, 4.8 Hz, 1 H), 1.99--2.07 (dm, J = 12.0 Hz, 1 H), 2.48--2.56 (m, 1 H), 2.61--2.69 (m, 2 H), 2.83--3.90 (m, 1 H), 3.94--

4.09 (m, 4 H), 4.22–4.30 (m, 2 H), 4.39 (dd, J = 11.8, 9.8 Hz, 1 H), 6.14 (broad d, J = 9.8 Hz, 1 H); ¹³C NMR (CDCl₃, 75.5 MHz) δ ; exact mass, m/z calcd for $C_{15}H_{21}F_3NO_6Si$ (M - C_4H_9)+ 396.1091, found 396.1088.

N-[(5 α ,8 β ,8a β)-5-[[Dimethyl(1,1-dimethylethyl)silyl]oxy]-7,7-(ethylenedioxy)-3,5,6,7,8,8a-hexahydro-3-oxo-1H-2-benzopyran-8-yl] trifluoroacetamide (271).

(a) N-[(4α,4aα,5β,8α,8aα)-5-[[Dimethyl(1,1-dimethylethyl)silyl]oxy]-7,7-(ethylenedioxy)octahydro-3-oxo-4-(phenylseleno)-1H-2-benzopyran-8-yl] trifluoroacetamide (270). Compound 269 (49 mg, 0.107 mmol) was first dissolved in warm, dry THF and then the solution was cooled to -78 °C. To this cold (-78 °C) and stirred mixture, a cold (-78 °C) solution of LDA (0.25 M in THF, 1.28 mL, 0.321 mmol) was added over 15 sec followed by dry HMPA (180 μL). The cold bath was removed, the mixture was allowed to attain 0 °C (ca 10 min) and was then stirred at that temperature for 30 min, and then cooled to -78 °C again, at which point and benzeneselenyl bromide (0.77 M in THF, 0.95 mL, 0.749 mmol) was injected rapidly (ca 2 sec). The resulting solution was stirred at -78 °C for 10 min, quenched with saturated aqueous sodium bicarbonate (4 mL), and diluted with ether (15 mL). The organic layer was washed with 10% w/v aqueous copper sulfate (1 x 4 mL), water (1 x 4 mL),

and dried (MgSO₄). Evaporation of the solvent left a brown-orange residue which was washed with a little hexane in order to remove most of the diphenyl diselenide present. Flash chromatography of the remaining yellowish solid over silica gel (15 x 150 mm) using first 5% ethyl acetate-hexane and then 35% ethyl acetate-hexane gave 270 (42 mg, 64%) as a white solid.

(b) $N-[(5\alpha,8\beta,8a\beta)-5-[[Dimethyl(1,1-dimethylethyl)silyl]oxy]-7,7-(ethy$ lenedioxy)-3,5,6,7,8,8a-hexahydro-3-oxo-1H-2-benzopyran-8-yl] trifluoroacet-L, 0.885 mmol) and then 30% w/w aqueous amide (271). Py.: 11.77 mmol) were added to a stirred solution of hydrogen peroxiae 270 (95 mg, 0.1%, 1.5%) 4/2 1.5:1 THF--dichloromethane (6 mL). The mixture was stirred for 3 h at room temperature and diluted with ethyl acetate (20 mL). The organic layer was washed with 10% w/v aqueous sodium bisulfite (1 x 4 mL), 10% w/v aqueous copper sulfate (1 x 4 mL), and water (1 x 4 mL), and dried (MgSO₄). Evaporation of the solvent and flash chromatography of the residue over silica gel (10 x 150 mm) using 35% ethyl acetate--hexane gave 271 (64.5 mg, 92%) as a white solid: FT-IR (CHCl₃ cast) 3350, 1706 cm⁻¹; ¹H NMR (CDCl₃, 400 MHz) δ 0.11 (s, 6 H), 0.93 (s, 9 H), 1.76 (dd, J = 13.8, 12.4 Hz, 1 H), 2.23 (dd, J = 13.8, 5.6 Hz, 1 H), 2.68--2.78 (m, 1 H), 3.88--3.94 (m, 1 H), 4.02--4.18 (m, 4 H), 4.22 (dd, J = 12.2, 8.2 Hz, 1 H), 4.38-4.45 [m, including dd (J = 12.2, 8.2 Hz, 1 H)]8.2 Hz) at δ 4.42, 2 H], 6.18 (t, J = 2.0 Hz, 1 H), 6.45--6.52 (broad d, J = 8.2 Hz, 1 H); 13C NMR (CD₃COCD₃, 106.6 MHz) δ -4.94, -4.75, 18.4, 26.09, 36.82, 43.81, 55.22, 55.30, 66.56, 66.60, 67.76, 69.46, 108.16, 113.63, 160.80, 163.92; exact mass, m/zcalcd for C₁₉H₂₈F₃NO₆Si 451.1639, found 451.1639.  $(3\alpha,4a\beta,5\alpha,8\beta,8a\beta)$ -8-(N-Chloroamino)-5-[[dimethyl(1,1-dimethylethyl)-silyl]oxy]-7,7-(ethylenedioxy)octahydro-3-[[triethylsilyl]oxy]-1H-2-benzopyran (276).

As tert-butyl hypochlorite is rather light sensitive, the reaction mixture as well as the solution of the reagent should be protected from light using aluminum foil. The reaction should also be closely monitored (TLC) and stopped a little short of completion to minimize bis-chlorination. A solution of freshly prepared tert-butyl hypochlorite (94 mg, 0.87 mmol) in dry ether (2 mL) was added over 20 min (syringe pump) to a cold (- 45 °C) and vigorously stirred solution of 267 (303 mg, 0.64 mmol) in 1:2 THF--ether (6 mL). The cold bath was removed and the mixture was allowed to reach room temperature (15 min). Evaporation of the solvent and flash chromatography of the residue over silica gel (10 x 150 mm) using 6--10% ethyl acetate--hexane gave 276 (250 mg, 77%) as a colorless oil: 1 H NMR (CDCl₃, 400 MHz) δ 0.03 (s, 6 H), 0.64 (q, J = 7.8 Hz, 9 H), 0.86 (s, 9 H), 0.96 (t, J = 7.8 Hz, 9 H), 1.41 (dt, J = 13.8, 10.0 Hz, 1 H), 1.62--1.81 (m, 3 H), 1.82 (ddd, J = 13.8, 4.0, 1.8 Hz, 1 H), 2.09--2.20 (m, 1 H), 3.40 (dd, J = 12.0, 4.0 Hz, 1 H), 3.45 (ddd, J = 12.0, 2.4 Hz, 1 H), 3.91--4.07

[#] If some bischlorinated coumpound is obtained, it can be reconverted into 267 by dissolving it in ether and washing the resulting solution with 10% w/v aqueous sodium bisulfite

 $(3\alpha,4a\beta,5a,8a\beta)-5-[[Dimethyl(1,1-dimethylethyl)silyl]oxy]-7,7-(ethylene-dioxy)octahydro-3-[[triethylsilyl]oxy]-8H-2-benzopyran-8-one (278).$

1,8-Diazabicyclo[5.4.0]undecane (0.368 mL, 2.46 mmol) was added to a stirred solution of 276 (250 mg, 0.493 mmol) in dry toluene (15 mL). The mixture was lowered into an oil bath and allowed to reach reflux temperature over 20 min. The mixture was refluxed for 40 min and then cooled to room temperature. Saturated aqueous ammonium civiloride (10 mL) was added and stirring was continued at room temperature for 15 min in order to hydrolyse the imine. The mixture was diluted with ether (25 mL), and the organic layer was washed with 10% w/v aqueous copper sulfate (2 x 10 mL), and water (1 x 10 mL), and dried (MgSO₄). Evaporation of the solvent and flash chromatography of the residue over silica gel (15 x 150 mm) using 20--30% ethyl acetate--hexane gave 278 (202 mg, 87%) as a colorless oil: FT-IR (CHCl₃ cast) 1738 cm⁻¹; ¹H NMR (CDCl₃, 400 MHz) δ 0.10 (s, 6 H), 0.62 (q, J = 8.0 Hz, 6 H), 0.88 (s, 9 H), 0.94 (t, J = 8.0 Hz, 9 H), 1.18 (dt, J = 13.8, 9.0 Hz, 1 H), 1.92--1.98 (dm, J = 13.0 Hz, 1 H), 2.03 (ddd, J = 14.0, 5.0, 1.6 Hz, 1 H), 2.19 (dd, J = 13.8, 12.0

Hz, 1 H), 2.36--2.44 (m, 1 H), 2.56--2.60 (m, 1 H), 3.35 (dd, J = 11.8, 3.0 Hz, 1 H), 3.72--3.77 (m, 1 H), 3.95--4.07 (m, 1 H), 4.12--4.18 (m, 1 H), 4.43 (dt, J = 12.0, 4.6 Hz, 1 H), 4.52 (dd, J = 12.0, 1.0 Hz, 1 H), 4.62 (dd, J = 9.0, 1.8 Hz, 1 H); 13 C NMR (CDCl₃, 106.6 MHz) δ -4.87, -4.71, 4.99, 6.69, 18.00, 25.71, 30.81, 39.77, 41.91, 42.65, 62.54, 64.44, 66.05, 67.48, 97.22, 104.66, 202.24; exact mass, m/z calcd for $C_{21}H_{39}O_6Si_2$ (M - C_2H_5) 443.2285, found 443.2275. Anal. Calcd for $C_{23}H_{44}O_6Si_2$: C, 58.43; H, 9.38 Found: C, 58.45; H, 9.23.

 $(3\alpha,4a\beta,5a,8a\beta)$ -5-[[Dimethyl(1,1-dimethylethyl)silyl]oxy]-7,7-(ethylene-dioxy)octahydro-3-[[triethylsilyl]oxy]-8H-2-benzopyran-8-one O-benzyl oximes (279a and 279b).

C Benzylhydroxylamine hydrochloride (280 mg, 1.76 mmol) and powdered molecular sieves 4Å (50 mg) were added to a stirred solution of 278 (144 mg, 0.3 mmol) in absolute ethanol (6 mL) and pyridine (0.1 mL). The mixture was stirred at room temperature for 3 h and was then diluted with ether (50 mL). The resulting mixture was washed with 10% w/v aqueous copper sulfate (2 x 5 mL), and water (1 x 5 mL), and dried (MgSO₄). Evaporation of the solvent and flash chromatography of the residue over silica gel (10 x 150 mm) using 10% ethyl acetate--hexane gave 279a and 279b (133 mg, 75%) as a gummy solid: ¹H NMR (CDCl₃, 200 MHz) δ 0.05 (s) and 0.07

(s) [both signals together correspond to 6 H], 0.54--0.75 (m, 6 H), 0.88 (s, 9 H), 0.92--1.03 (m, 9 H), 1.17--1.43 (m, 0.67 H), 1.62--2.25 (m, 4 H), 2.32--2.40 (m, 0.67 H), 2.94 (dd, 11.2, 5.0 Hz, 0.33 H), 3.42 (dd, 11.8, 3.3 Hz, 0.67 H), 3.55--4.15 (m, call 3.67 H), 4.16 (dt, J = 12.0, 5.3 Hz, 0.67 H), 4.41 (dd, J = 12.0, 5.3 Hz, 0.33 H), 4.52 (d, J = 11.5 Hz, 0.67 H), 4.70 (dd, J = 9.0, 2.0 Hz, 0.67 H), 4.90 (dd, J = 8.7, 3.8 Hz, 0.33 H), 5.03--5.21 (m, 2 H), 7.25--7.47 (m, 5 H); exact mass, m/z calcd for $C_{30}H_{51}NO_6Si_2$ 577.3254, found 577.3247.

 $(4a\alpha,5\beta,8a\alpha)$ -5-[[Dimethyl(1,1-dimethylethyl)silyl]oxy]-7,7-(ethylene-dioxy)tetrahydro-1H-2-benzopyran-3,8-(4H,7H)-dione O-benzyl oximes (280a and 280b).

Pyridinium chlorochromate (194 mg, 0.9 mmol) and powdered molecular sieves 4Å (50 mg) were added to a stirred solution of 279a and 279b (130 mg, 0.225 mmol) in dry dichloromethane (5 mL). The mixture was stirred for 16 h at room temperature. Flash chromatography (no work-up) of the mixture on silica gel (20 x 180 mm) using ethyl acetate--hexane 30--40%, gave 280a and 280b (94 mg, 90 %) as a white semi-solid: FT-IR (CHCl₃ cast) 1737 cm⁻¹; ¹H NMR (CDCl₃, 400 MHz) δ 0.6 (s) and 0.7 (s) and 0.8 (s) and 0.9 (s) [all signals together correspond to 9 H], 1.97 (dd, J = 14.4, 5.0 Hz, 1 H), 2.14 (dd, J = 14.4, 9.6 Hz, 1 H),

2.20 (d, J = 4.6 Hz, 1 H), 2.30 (dd, J = 17.6, 12.0 Hz, including m at δ 2.26--2.31, 1.35 H), 2.48--2.68 (m, 2.0 H), 2.92 (dd, J = 8.6, 4.2 Hz, 0.66 H), 3.59--3.72 (m, 1 H), 3.84--4.0 (m, 3.33 H), 4.12--4.22 (m, 1 H), 4.24--4.30 (m, 1 H), 4.74 (dd, J = 11.6, 3.8 Hz, 0.66 H), 4.82 (dd, J = 10.4, 12.0 Hz, 0.33 H), 5.08 ald, J = 16.8, 12.0 Hz, 1.34 H), 5.15 (s, 0.66 H), 7.27--7.40 (m, 5.0 H); ¹³C NMR (CDCl₃, 106.6 MHz) δ -5.09, -4.90, -4.68, -4.52, 17.66, 17.92, 25.66, 27.23, 31.64, 32.24, 35.95, 36.36, 37.72, 41.23, 41.76, 64.13, 64.19, 65.00, 65.46, 67.15, 67.98, 68.50, 69.53, 76.63, 77.45, 104.31, 105.10, 127.96, 128.11, 128.35, 128.39, 128.46, 128.55, 137.37, 137.47, 150.02, 153.21, 170.14, 170.60; exact mass, m/z calcd for C₂₄H₃₅NO₆Si 461.2234, found 461.2231. Anal. Calcd for C₂₄H₃₅NO₆Si: C, 62.44; H, 7.64; N, 3.03 Found: C, 62.22; H, 7.46; N, 2.95.

 $(5\alpha,8a\beta)$ -5-[[Dimethyl(1,1-dimethylethyl)silyl]oxy]-7,7-(ethylenedioxy)-5,6,7,8-tetrahydro-3H-2-benzopyran-3,8-dione O-benzyl oximes (282a and 282b).

(a) $(4\alpha,4a\alpha,5\beta,8a\alpha)$ -5-[[Dimethyl(1,1-dimethylethyl)silyl]oxy]-7,7-(ethylenedioxy)-tetrallydro-4-(phenylseleno)-1H-2-benzopyran-3,8-(4H,7H)-dione O-benzyl oximes (281a and 281b). A cold (-78 °C) solution of LDA (0.25 M in THF, 0.728 mL, 0.182 mmol) was added over 15 sec to a cold (-78 °C) and stirred solution of 280a and 280b (70 mg, 0.151 mmol) in dry THF (2 mL). The

mixture was stirred at -78 °C for 1.5 h. A solution of benzeneselenyl bromide (0.77 M in THF, 0.273 mL, 0.21 mmol) [prepared by adding bromine (20 gH, 0.39 mmol) to a vigorously stirred solution of diphenyl diselenide (135 mg, 0.43 mmol) in dry THF (1 mL)] was injected rapidly (2 sec) to the cold solution. After being stirred at -78 °C for 15 min, the mixture was quenched with saturated aqueous sodium bicarbonate (1 x 4 mL), and diluted with ether (15 mL). The organic layer was washed with water (1 x 4 mL), and dried (MgSO₄). Evaporation of the solvent and flash chromatography of the yellowish, solid residue over silica gel (15 x 150 mm) using 10% ethyl acetate--hexane gave 281a and 281b (74 mg, 79%) as a slightly yellow oil.

(b) $(5\alpha,8a\beta)$ -5-[[Dimethyl(1,1-dimethylethyl)silyl]oxy]-7,7-(ethylened)oxy)-5,6,7,8-tetrahydro-3H-2-benzopyran-3,8-dione O-benzyl oximes (282a and 282b). Dimethyldioxirane⁶⁸ (0.020 M in acetone, 5 mL, 0.10 mmol) was added over 1 min to a cold (- 78 °C) and stirred solution of 281a and 281b (38 mg, 0.062 mmol) in dichloromethane (0.5 mL). The cold bath was removed and the mixture was allowed to reach room temperature (30 min). The mixture was then diluted with ether (15 mL) and washed with saturated aqueous sodium bicarbonate (2 x 4 mL), and brine (1 x 4 mL) and dried (MgSO₄). Evaporation of the solvent gave 282a and 282b (30 mg, ca 100%) as a colorless oil that > 95% pure [1H NMR (400 MHz)]: FT-IR (CHCl₃ cast) 1733 cm-1; 1H NMR (CDCl₃, 400 MHz) δ 0.10 (s) and 0.12 (s) [both signals together correspond to 6 H], 0.90 (s) and 0.93 (s) [both signals together correspond to 9 H), 2.04-2.13(m, 1 H), 2.20 (dd, J = 15.2, 6.0 Hz, 0.5 H), 2.74 (dd, J = 14.0, 9.6 Hz, 0.5 H), 3.52-3.58 (m, 1 H), 3.73--3.80 (m, 0.5 H). 3.92--4.00 (m, 3 H), 4.10--4.21 (m, 2 H), 4.38--4.44 (tm, J = 9.0 Hz) and 4.44 (dd, J = 12.0, 9.0 Hz), 4.53-4.61 (m, 1.0 H), 4.61-4.67(ddm, J = 11.6, 6.0 Hz, 0.5 H), 5.07 (dd, J = 16.0, 12.0 Hz, 1 H), 5.17 (s, 1 H), 6.12 (t, 1 H $J = 2.2 \text{ Hz}, 0.5 \text{ H}), 6.15 \text{ (t, } J = 2.2 \text{ Hz}, 0.5 \text{ H}), 7.29--7.40 \text{ (m. 5 H); } ^{13}\text{C NMR (CDCl}_3,$

106.6 MHz) δ -5.00, -4.91, -4.80, 18.16, 25.73, 25.76, 34.31, 37.49, 44.36, 44.54, 63.86, 64.71, 65.75, 65.88, 65.95, 67.04. 67.10, 68.18, 77.37, 77.72, 104.89, 104.97, 112.70, 113.18, 128.16, 128.41, 128.50, 128.60, 136.80, 137.11, 149.46, 150.30, 159.58, 160.25, 163.76, 164.29; exact mass, *m/z* calcd for C₂₀H₂₄NO₆Si 402.1373, found 402.1389.

5-[[Dimethyl(1,1-dimethylethyl)silyl]oxy]-7,7-(ethylenedioxy)-5,6-dihydro-1*H*-2-benzopyran-3,8-(4*H*,7*H*)-dione *O*-benzyl oximes (283a and 283b).

When 282a and 282b is subjected to flash chromatography, it isomerizes almost completely to 283a and 283b: FT-IR (CHCl₃ cast) 1748 cm⁻¹; ¹H NMR (CDCl₃, 400 MHz) δ 0.12 (s) and 0.14 (s) [both signals together correspond to 6 H], 0.89 (s) and 0.91 (s) [both signals together correspond to 9 H), 2.08 (dd, J = 10.0 Hz, 0.3 H), 2.18 (dd, J = 13.0, 9.4 Hz, including a multiplet at 2.14--2.19, 1.0 H), 2.35 (dd, J = 13.0, 6.0 Hz, 0.70 H), 2.97--3.26 (m, ca 1.70 H), 3.42---3.49 (m, ca 0.3 H), 3.75--4.18 (m, 4 H), 4.42--4.51 (m, 1 H), 5.05--5.09 (m, 0.5 H), 5.09--5.18 (m, 2 H), 5.20--5.25 (m, ca 1.25 H), 7.30--7.40 (m, 5 H); exact mass, m/z calcd for $C_{20}H_{24}NO_6Si$ 402.1375, found 402.1372.

APPENDIX 1

X-RAY CRYSTAL STRUCTURE OF THE 3,5-DINITROBENZOATE DERIVATIVE OF 34

EXPERIMENTAL

Data Collection

A clear, colorless, thin crystal of $C_{17}H_{16}N_2O_8$, with the approximate dimensions of $0.057 \times 0.240 \times 0.270$ mm, was mounted on a glass fiber with epoxy, and optically centered in the x--ray beam of an Enraf-Nonius CAD4 automated diffractometer. The prominent face was the [100], and the two smaller faces were the [010] and [001] faces. The crystal was cooled to approximately -20C, using a cold air stream apparatus, and all measurements were made at this temperature. All intensity measurements were performed using Mo K α radiation (λ = 0.7107 Å) with a graphite crystal, incident beam monochromator.

The automatic peak search and reflection indexing programs generated a monoclinic cell. The systematic absences of hol, l odd, 0k0, k odd, and the magnitude of the unit cell volume led to the unique choice of space group as $P2_1/c$ (No.~14)² The cell constants and orientation matrix were obtained from a least-squares refinement of the setting angles of 25 reflections in the range 7.8<0<14.8°. The unit cell parameters are given in Table 1.

¹The diffractometer programs are those supplied by Enraf-Nonius for operating the operating the CAD4F diffractometer; some local modifications by Dr. R. G. Ball.

²International Tables for X-Ray Crystallography (1969). Vol. I. Birmingham: Kynoch Press.

The intensity data were collected with θ -2 θ scans at fixed speed, 5.0° min⁻¹ (in θ). The scan range was varied as a function of θ to compensate for the α_1 - α_2 wavelength dispersion: ω scan width = 1.00 + 0.347tan θ .

The backgrounds for the peaks were measured by extending the scan 25% on each side of the calculated range; this gave a peak--to--background counting time ratio of 2:1. The crystal did not diffract well, and the intensity measurements were made out to a maximum 2θ of 40° . Three reflections were chosen as standard reflections, and were remeasured after every 120 min of exposure time to check on crystal and electronic stability over the course of data collection. There was a change in intensity of roughly $\pm 4\%$ over the time span of data collection. This was considered negligible, and no decay correction was used. Several other crystals were examined, but there was no significant diffraction beyond the $2\theta = 40^{\circ}$ limit. (Only about 5% of the reflections at higher angle had intensities greater than three times their estimated standard deviations.)

Data Reduction

A total of 4167 reflections were collected, and Lorentz and polarization factors were applied: I = r(S - 2B)/Lp and $\sigma_I = [r(S + 4B) + (0.04I)^2]^{1/2}/Lp$, where r is the scan rate, S is the total scan count, B is the total background count, and Lp is the combined Lorentz and polarization factor.

Structure Solution and Refinement

The structure was solved using the direct methods program MITHRIL³ \ref{.}, in which all 27 non-hydrogen atoms were located; R began at 0.18.

Adjustment⁴ of atomic parameters was carried out by full--matrix least-squares refinement on F_0 minimizing the function $\Sigma \|F_0\| - \|F_0\|^2$ where $\|F_0\|$ and $\|F_0\|$ are the observed and calculated structure factor amplitudes and the weight is $4F_0^2/\sigma^2(F_0^2)$. The neutral atom scattering factors were calculated from the analytical expression for the scattering factor curves⁵. The f' and f' components of anomalous dispersion⁶ were included in the calculations of all non-hydrogen atoms.

The hydrogen atoms were generated at idealized calculated positions by assuming a C--H bond length of 0.95Å and the appropriate sp² or sp³ geometry. The positions of the hydrogen atoms on the C(19) methyl group were generated a by least--squares refinement of the coordinates derived from a difference Fourier map. The hydrogen atoms were then included in the calculations with fixed, isotropic Gaussian parameters 1.2 times that of the attached atom and constrained to 'ride' on the attached atom. The refinement of the coordinates and isotropic U's for all non--hydrogen atoms was

6 ibid., Table 2.3.1.

³Gilmore, C. J. (1983). MITHRIL 83. A Multiple Solution Direct Methods Program. University of Glasgow

⁴The computer programs used in this analysis include the Enraf-Nonius Structure Determination Package. Version 3 (1985, Delft, The Netherlands) adapted for a SUN Microsystems 3/160 computer, and several locally written programs by Dr. R. G. Ball

⁵International Tables for X-Ray Crystallography (1974). Vol. IV. Table 2.2B. Birmingham: Kynoch Press. (Present distributor D. Reidel, Dordrecht.)

continued to convergence. At that stage, the data were corrected for absorption by use of an empirical scheme based on the absorption surface (Fourier filtering) method of Walker and Stuart⁷. The maxin im and minimum correction factors applied to F_0 were 1.4320 and 0.732. After averaging over 2/m symmetry (R-merge on F is 0.096) and deleting the systematic absences, there were 1719 averaged reflections, 1004 with $I > \sigma_I$. In the final cycle, 244 parameters were refined with the 1004 observations having $I > \sigma_I$ and the largest and and average shift/error ratio in the final cycle was less than 0.01. As a result, the final goodness--of--fit was 1.39, and $R_1 = \sum |I - F_0| |I - F_$

Table 1. Experimental Details

A. Crystal Data

 $C_{17}H_{16}N_2O_8$ FW = 376.33

Crystal dimensions: $0.057 \times 0.240 \times 0.270 \text{ mm}$

monoclinic space group P2₁/c

a=16.454(8), b=14.693(6), c=7.266(3) Å, $\beta=91.88(4)^{\circ}$

 $V = 1755 \ \text{Å}^3; \ Z = 4; \ D_c = 1.421 \ \text{g cm}^{-3}; \ \mu = 1.08 \ \text{cm}^{-1}$

B. Data Collection and Refinement Conditions

Radiation: Mo K α , $\lambda = 0.7107$ Å

Monochromator: incident beam, graphite crystal

Take-off angle: 3.00°

Detector aperture: 2.40 mm horiz × 4.0 mm vert

Crystal-to-detector distance: 205 mm

Scan type: $\theta - 2\theta$

Scan rate: 5.00min-1

Scan width: $1.00 + 0.347 \tan \theta$

Data collection 20 limit: 40°

Data collection index range: $+h,+k,\pm l$

Number of Reflections: 1719 total, averaged; 1004 with I>σ_I

Observations:variables ratio: 1004: 244

Agreement factors R₁, R₂, GOF: 0.072, 0.064, 1.39

Corrections applied: empirical absorption surface
