ABSTRACT

The linear stability problems for the onset of secondary flow driven by buoyancy force in a class of horizontal laminar fluid flows including plane Poiseuille, Hartmann and Blasius flows are investigated by a numerical method. The low Peclet number thermal entrance region problem in parallel-plate channels with unequal constant wall temperatures considers axial heat conduction effect and allows heat penetration through the thermal entrance. The solution is obtained by the eigenfunction expansion method employing Gram-Schmidt orthonormalization procedure. The axial conduction effects on convective instability of a horizontal plane Poiseuille flow in the thermal entrance region with respect to both longitudinal and transverse vortex disturbances are studied. It is found that the transverse vortex disturbances are the preferred mode over that of longitudinal disturbances for $Pe \leq 1$ and $Pr \geq 1$ (low Re) in the developing regions upstream and downstream of the thermal entrance. For other conditions, the longitudinal rolls have priority of occurrence. The maximum density effects on convective instability of water in the temperature range $0 \sim 30^\circ\text{C}$ are also studied by using the same basic state temperature solution. The effects of viscous dissipation on the onset of instability for longitudinal vortices in the thermal entrance region of

a horizontal parallel-plate channel heated from below are also studied.

The basic flow solution of Hartmann flow considers axial conduction, viscous dissipation and Joulean heating effects but neglects axial heat penetration through the thermal entrance. The convective instability analysis of horizontal Hartmann flow in the thermal entrance region considers the effects of Prandtl, Peclet, Brinkman and Hartmann numbers.

The maximum density effects on thermal instability in a thin horizontal water layer induced by combined buoyancy, and surface tension gradients are studied by a numerical method. The instability results provide further physical insight into the problem considered by Nield in 1964.

The convective instability analysis of Blasius flow along a horizontal semi-infinite plate with uniform wall temperature complements the hydrodynamic instability analysis of laminar boundary layers reported in the literature. The instability analysis is further extended to include the maximum density effect.

The heat transfer results for thermal entrance region problems of plane Poiseuille flows are also obtained using the basic flow solutions.

ACKNOWLEDGEMENTS

The author wishes to express his sincere appreciation to the following persons and organizations:

Dr. K.C. Cheng, thesis adviser, for his guidance and assistance in all stages of this investigation and in the preparation of this thesis.

The Department of Mechanical Engineering and the National Research Council of Canada for providing financial assistance in the form of assistantship and scholarship.

My wife, Helen Fu-mei, for her constant encouragement and patience throughout the course of his graduate studies.

Miss Susan Schultz for her excellent typing of the thesis.

Fellow Graduate Students in Mechanical Engineering for their helpful discussions on various aspects of the thesis work.

CHAPTER I.

INTRODUCTION

The Benard problem and the related thermal instability problem for horizontal fluid layers have been investigated extensively in recent years. The literature on thermal instability is very extensive. An excellent account of the hydrodynamic and hydromagnetic stability was given by Chandrasekhar [1] in 1961. Since then several review articles [2-7] have also appeared in the literature.

The thermal instability for the onset of stationary longitudinal vortex rolls in a horizontal plane Poiseuille flow was investigated theoretically by Nakayama, Hwang and Cheng [8] and experimentally by Akiyama, Hwang and Cheng [9]. The problem was further extended to the thermal entrance region considering axial conduction term in the energy equation for the basic flow by Hwang and Cheng [10]. The experimental investigations on convective instability in a horizontal plane Poiseuille flow heated from below were reported by Ostrach and Kamotani [11,12]. In the low Peclet number flow regime, the assumption of uniform fluid temperature at the thermal entrance is apparently unreasonable because of the upstream heat penetration through the thermal entrance. In low Peclet number flow regime, the

question regarding the onset of transverse vortex rolls [2] also arises.

Consideration is next given to the Hartmann flow in a horizontal parallel-plate channel heated from below. Physically, when an adverse temperature gradient exists in the direction opposite to the gravitational force, then the basic flow system is potentially unstable because of the top-heavy situation. Apparently, the onset of secondary flow in the form of stationary longitudinal vortices in the thermal entrance region of Hartmann flow is of practical interest.

Similarly, the thermal boundary layers in Blasius flow heated from below is also potentially unstable. For the laminar forced convection problems involving melting of ice or solidification of water, the maximum density effect on thermal instability is also of practical interest since one may wish to find the condition at which free convection starts to affect the flow. Apparently, the thermal instability of the Blasius flow has not been studied in the past.

In this thesis, the convective instabilities in plane Poiseuille, Hartmann and Blasius flows are studied by the method of small disturbances where a linearization about the basic flow is made. For the cases of plane Poiseuille and Blasius flows, the effects of maximum density on convective instability are also investigated. In the linear instability analysis for fully developed Hartmann flow in the thermal entrance region of a horizontal parallel-plate

channel, the effects of axial conduction, viscous and Joulean dissipations are included. In connection with the plane Poiseuille flow, the effects of viscous dissipation on thermal instability in the thermal entrance region of a horizontal parallel-plate channel heated from below are also studied. Finally, Nield's linear stability [13] for a horizontal liquid layer considering surface tension and buoyancy effects is extended to the case of water with maximum density effect for the temperature range $0 \sim 30^\circ\text{C}$.

In order to show clearly the physical problems considered in this thesis, the classification of the problems is given below (see Fig. 1):

1. Plane Poiseuille Flow

(a) Thermal Entrance Region Problem for Low Peclet Number Flow Regime (Basic Flow Solution),

$T_1 \neq T_2$, $T = T_0$ at $X = -\infty$ (Chapter II).

(b) Axial Conduction Effects on Convective Instability, $T_1 > T_2$, $T = T_0$ at $X = -\infty$ (Chapter III).

(c) Maximum Density Effects on Convective Instability, $T_1 > T_2$, $T = T_0$ at $X = -\infty$ (Chapter IV).

(d) Viscous Dissipation Effects on Convective Instability, $T_1 > T_2$, $T = T_0$ at $X = 0$ (Chapter V).

2. Hartmann Flow

(a) Basic Flow Solution with Axial Conduction, Joule Heating and Viscous Dissipation Effects, $T_1 \neq T_2$, $T = T_0$ at $X = 0$ (Chapter VI).

- (b) Magnetic Field Effects on Convective Instability, $T_1 > T_2$, $T = T_0$ at $X = 0$ (Chapter VII).
- 3. Horizontal Liquid Layer with Free Surface
 - (a) Maximum Density Effects on Thermal Instability Induced by Buoyancy and Surface Tension, $T_1 > T_{\max} > T_2$ (Chapter VIII).
- 4. Blasius Flow
 - (a) Convective Instability of Blasius Flow, $T_w > T_\infty$ (Chapter IX).
 - (b) Maximum Density Effects on Convective Instability of Blasius Flow, $T_w > T_{\max} > T_\infty$ (Chapter X).

A remark regarding the structure and the method of presentation for the present dissertation is now in order. After careful considerations, it is decided that each chapter will be treated independently. The independent presentation of each chapter affords one to discuss clearly the scope of each investigation and the results obtained therein. Thus the conclusions and significance for each problem may be assessed readily.

CHAPTER II

LOW PECKET NUMBER HEAT TRANSFER IN THE THERMAL ENTRANCE REGION OF PARALLEL-PLATE CHANNELS WITH UNEQUAL WALL TEMPERATURES

The problem of low-Peclet-number thermal entry heat transfer for plane Poiseuille flow in parallel-plate channels with uniform but unequal wall temperatures is approached by the eigenfunction expansion method utilizing the Gram-Schmidt orthonormalization procedure. The formulation considers axial heat conduction and allows upstream heat penetration through the thermal entrance. Numerical results are obtained for the case with entrance condition parameter $\theta_0 = -1$ and Peclet number $Pe = 1, 5, 10$ and 50 . The effect of Peclet number on temperature distributions in both upstream and downstream regions is studied. At $Pe = 50$, the concept of thermal boundary layer is applicable and the present series solution does not yield physically reasonable temperature distribution locally near the upper plate at the thermal entrance. The difficulty may be attributed to the nature of thermal boundary conditions at the thermal entrance and the transition from elliptic problem to parabolic problem with the increase of Peclet number.

Nomenclature

A_n, B_n, C_n, D_n	=	coefficients of series expansion in equations (5) and (6)
$a_n^j, b_n^j, c_n^j, d_n^j$	=	coefficients in equation (13)
f_j, s_j	=	orthonormal functions
h_1, h_2	=	local heat transfer coefficients at lower and upper plates
k	=	thermal conductivity
L, ℓ	=	height of channel and $L/2$
Nu_1, Nu_2	=	local Nusselt numbers, $h_1 \ell/k$ and $h_2 \ell/k$
Pe	=	Peclet number, $4 U_m \ell/\alpha$
$p_j^n, q_j^n, r_j^n, t_j^n$	=	coefficients in equation (14)
q_1, q_2	=	rates of heat transfer per unit area at lower and upper plates
T, T_0, T_1, T_2	=	fluid temperature, uniform entrance temperature, uniform but different lower and upper plate temperatures, respectively
T_b, T_m	=	bulk temperature and $(T_1 + T_2)/2$
U, U_m, u	=	axial and mean velocities, and U/U_m
X, Z	=	axial and transverse coordinates
x, z	=	dimensionless coordinates, $X/(3Pe\ell/8)$ and Z/ℓ

Y_n, R_n, F_n, Z_n = eigenfunctions

\bar{z} = transformed coordinate, $(z + 1)/2$

Greek Letters

α = thermal diffusivity

$\alpha_n, \beta_n, \gamma_n, \lambda_n$ = eigenvalues

δ_{ij} = Kronecker delta

θ, θ_0 = dimensionless temperature and uniform entrance temperature, $(T - T_m)/(T_2 - T_m)$ and $(T_0 - T_m)/(T_2 - T_m)$

$\theta_1, \theta_2, \theta_b$ = temperature distributions in the upstream and downstream regions and bulk temperature

ν = kinematic viscosity

ϕ, θ^* = dimensionless temperature profile, $(1 - \theta)/2$

$\psi_j, \tilde{\psi}_j$ = orthonormal functions

2.1 Introduction

When the axial heat conduction effect is important for the thermal entrance region problem in tubes or channels, the assumption of uniform entrance temperature at $X = 0$ used in the classical Graetz formulation [1] becomes physically unrealistic because of the upstream heat penetration. The elliptic energy equation with the axial conduction term has been solved by several investigators [2-6] considering the region extending from $X = -\infty$ to $X = \infty$ for fully developed laminar flow in tubes or channels using different theoretical solution methods. The thermal boundary conditions considered so far are either uniform wall temperature or uniform wall heat flux for the downstream region ($X \geq 0$) with the upstream region ($X < 0$) perfectly insulated. In addition, the fluid temperature is taken to be uniform at $X = -\infty$.

Considering the case of plane Poiseuille flow in horizontal parallel-plate channels, the thermal boundary conditions at the upper and lower plates may be different in practical applications. The interesting case of uniform but unequal wall temperatures [7] for Graetz problem does not appear to have been investigated in the past using the exact formulation [4] considering the axial heat conduction effect.

The purpose of this study is to present heat transfer results in the thermal entrance region of plane Poiseuille flow between two horizontal parallel plates maintained at

unequal but constant wall temperatures. The analysis is based on a rigorous formulation [4] and the main concern here is the heat transfer characteristics in the low Peclet number flow regime. The present analysis is motivated by the thermal instability analysis (Chapter III) for the onset of longitudinal and transverse rolls in parallel-plate channels heated from below and serves as a basic flow solution. As compared with the earlier works [2-6], the present problem involves two distinct sets of eigenvalues related to even and odd sets of eigenfunctions [7] whereas the published and analytical solutions are concerned only with even eigenvalues and eigenfunctions.

2.2 Theoretical Analysis

2.2.1 Governing Equations

Neglecting the viscous dissipation effects, the energy equation and the boundary conditions in dimensionless form for the thermal entrance region problem (see Fig. 1) with axial heat conduction can be written as [4]

$$\frac{2}{3} u \frac{\partial \theta}{\partial x} = \frac{\partial^2 \theta}{\partial z^2} + \left(\frac{8}{3Pe}\right)^2 \frac{\partial^2 \theta}{\partial x^2} \quad (1)$$

$$\theta_1(-\infty, z) = \theta_0, \quad \partial \theta_1(x, 1) / \partial z = -\partial \theta_1(x, -1) / \partial z = 0$$

$$\text{for } -\infty < x \leq 0 \quad (2)$$

$$\theta_2(\infty, z) = 0, \theta_2(x, 1) = 1, \theta_2(x, -1) = -1 \quad \text{for } 0 \leq x < \infty \quad (3)$$

$$\theta_1(0, z) = \theta_2(0, z), \quad \partial \theta_1(0, z) / \partial x = \partial \theta_2(0, z) / \partial x \quad \text{at } x = 0 \quad (4)$$

where the dimensionless variables are defined in Nomenclature and $u = (3/2)(1 - z^2)$ for plane Poiseuille flow. As $Pe \rightarrow \infty$, one recovers the case of negligible axial conduction [1].

2.2.2 Solution

The temperature distributions in the adiabatic and the thermal entrance regions satisfying the conditions at $x = \pm \infty$ are sought in the following form [4,7]:

$$\theta_1(x, z) = \theta_0 + \sum_{n=1}^{\infty} B_n Y_n(z) \exp(\alpha_n^2 x) + \sum_{n=1}^{\infty} A_n F_n(z) \exp(\epsilon_n^2 x), \quad -\infty < x \leq 0 \quad (5)$$

$$\theta_2(x, z) = z + \sum_{n=1}^{\infty} C_n R_n(z) \exp(-\beta_n^2 x) + \sum_{n=1}^{\infty} D_n Z_n(z) \exp(-\gamma_n^2 x), \quad 0 \leq x < \infty \quad (6)$$

where α_n , ϵ_n , and β_n , γ_n are the even and odd eigenvalues and eigenfunctions, respectively, for the adiabatic region.

Similarly, β_n , γ_n ; and R_n , Z_n are the even and odd eigenvalues and eigenfunctions, respectively, for the thermal entrance region. The associated characteristic equations and boundary conditions are:

$$\frac{d^2 Y_n}{dz^2} + \alpha_n^2 \left[\left(\frac{8\alpha_n}{3Pe} \right)^2 - (1 - z^2) \right] Y_n = 0, \quad dY_n(+1)/dz = 0 \quad (7)$$

$$\frac{d^2 F_n}{dz^2} + \epsilon_n^2 \left[\left(\frac{8\epsilon_n}{3Pe} \right)^2 - (1 - z^2) \right] F_n = 0, \quad dF_n(+1)/dz = 0 \quad (8)$$

$$\frac{d^2 R_n}{dz^2} + \beta_n^2 \left[\left(\frac{8\beta_n}{3Pe} \right)^2 + (1 - z^2) \right] R_n = 0, \quad R_n(+1) = 0 \quad (9)$$

$$\frac{d^2 Z_n}{dz^2} + \gamma_n^2 \left[\left(\frac{8\gamma_n}{3Pe} \right)^2 + (1 - z^2) \right] Z_n = 0, \quad Z_n(+1) = 0 \quad (10)$$

It is noted that as $Pe \rightarrow \infty$, the set of equations (9) and (10) reduces to the type of the Graetz problem [1]. In this study, equations (7) to (10) are solved numerically by using a fourth-order Runge-Kutta method [9]. Two hundred equal steps are employed and the boundary conditions at $z = 0$ are used as the starting point. The eigenvalues are improved by using the variable secant method [9] which requires assuming two trial values with a difference of say 0.005 at the start. The even eigenvalues β_n are listed

in reference [4] for $Pe = 1, 5, 10, 50$ and can be used as the initial values in this study. The number of iterations required to have a tolerance of $dY_n(1)/dz, dF_n(1)/dz, R_n(1),$ or $Z_n(1) < 10^{-8}$ depends on the initial guess for each eigenvalue but it usually takes 3 to 7 iterations. The spectrum of the eigenvalues is checked by plotting $\alpha_n, \epsilon_n, \beta_n$ or γ_n versus n . The eigenvalues for $Pe = 1, 5, 10, 50$ are listed in Tables 1 and 2. The even eigenvalues α_n, β_n are found to agree with those reported in reference [4].

The series expansion coefficients A_n, B_n, C_n, D_n are determined by applying the matching conditions at $x = 0$, equation (4), for the two regions. Substituting equations (5) and (6) into (4) yields:

$$\sum_{n=1}^{\infty} C_n R_n(z) - \sum_{n=1}^{\infty} B_n Y_n(z) = \theta_0, \quad \sum_{n=1}^{\infty} C_n \beta_n^2 R_n(z) + \sum_{n=1}^{\infty} B_n \alpha_n^2 Y_n(z) = 0 \quad (11)$$

$$\sum_{n=1}^{\infty} D_n Z_n(z) - \sum_{n=1}^{\infty} A_n F_n(z) = -z, \quad \sum_{n=1}^{\infty} D_n \gamma_n^2 Z_n(z) + \sum_{n=1}^{\infty} A_n \epsilon_n^2 F_n(z) = 0 \quad (12)$$

Since the axial conduction term is retained, the eigen-

functions lack the orthogonality property and the eigenfunction expansion technique commonly used for the Sturm-Liouville system cannot be used here in evaluating the series expansion coefficients. Following the procedure described in reference [4], the four complete sets of trial orthonormal functions in terms of Y_n , F_n , R_n , and Z_n , respectively, can be constructed by a linear combination in the following form:

$$\begin{aligned}\phi_j &= \sum_{n=1}^j b_n^j Y_n(z), & f_j &= \sum_{n=1}^j d_n^j F_n(z), \\ \psi_j &= \sum_{n=1}^j a_n^j R_n(z), & s_j &= \sum_{n=1}^j c_n^j Z_n(z)\end{aligned}\tag{13}$$

where $\int_0^1 \phi_i \phi_j dz = \delta_{ij}$, $j = 1, 2, \dots$ and a similar relationship holds for f_j , ψ_j and s_j . The Gram-Schmidt orthonormalization procedure can now be applied step by step as described in references [4,10]. By the following linear transformations [4], the eigenfunctions can be expressed conversely in terms of the orthonormal functions as

$$\begin{aligned}Y_n(z) &= \sum_{j=1}^n q_j^n \phi_j(z), & F_n(z) &= \sum_{j=1}^n r_j^n f_j(z) \\ R_n(z) &= \sum_{j=1}^n p_j^n \psi_j(z), & Z_n(z) &= \sum_{j=1}^n t_j^n s_j(z).\end{aligned}\tag{14}$$

The coefficients q_j^n , r_j^n , p_j^n and t_j^n can be obtained from the matrix equations $[q] = [b]^{-1}$, $[r] = [d]^{-1}$, $[p] = [a]^{-1}$ and $[t] = [c]^{-1}$. Substituting equation (14) into equations (11) and (12), one obtains

$$\sum_{n=1}^{\infty} C_n \left(\sum_{j=1}^n p_j^n \psi_j \right) - \sum_{n=1}^{\infty} B_n \left(\sum_{j=1}^n q_j^n \phi_j \right) = \theta_0 \quad (15)$$

$$\sum_{n=1}^{\infty} C_n \beta_n^2 \left(\sum_{j=1}^n p_j^n \psi_j \right) + \sum_{n=1}^{\infty} B_n \alpha_n^2 \left(\sum_{j=1}^n q_j^n \phi_j \right) = 0$$

$$\sum_{n=1}^{\infty} D_n \left(\sum_{j=1}^n r_j^n s_j \right) - \sum_{n=1}^{\infty} A_n \left(\sum_{j=1}^n t_j^n f_j \right) = -z \quad (16)$$

$$\sum_{n=1}^{\infty} D_n \gamma_n^2 \left(\sum_{j=1}^n r_j^n s_j \right) + \sum_{n=1}^{\infty} A_n \epsilon_n^2 \left(\sum_{j=1}^n t_j^n f_j \right) = 0$$

By noting the orthonormal properties for ψ_j , ϕ_j , s_j and f_j , one obtains the following sets of equations after truncating the infinite series at $n = N$.

$$\sum_{n=1}^N C_n \left(\sum_{j=1}^n p_j^n \delta_{ij} \right) - \sum_{n=1}^N B_n \left(\sum_{j=1}^n q_j^n \int_0^1 \phi_j \psi_i dz \right) = \int_0^1 \theta_0 \psi_i dz \quad (17)$$

$$\sum_{n=1}^N C_n \beta_n^2 \left(\sum_{j=1}^n p_j^n \int_0^1 \psi_j \phi_i dz \right) + \sum_{n=1}^N B_n \alpha_n^2 \left(\sum_{j=1}^n q_j^n \delta_{ij} \right) = 0$$

$$\sum_{n=1}^N D_n \left(\sum_{j=1}^n r_j^n \delta_{ij} \right) - \sum_{n=1}^N A_n \left(\sum_{j=1}^n t_j^n \int_0^1 f_j s_i dz \right) = - \int_0^1 z s_i dz$$

$$\sum_{n=1}^N D_n \gamma_n^2 \left(\sum_{j=1}^n r_j^n \int_0^1 s_j f_i dz \right) + \sum_{n=1}^N A_n \epsilon_n^2 \left(\sum_{j=1}^n t_j^n \delta_{ij} \right) = 0 \quad (18)$$

In this study, N is taken to be 20 for $Pe = 1, 5, 10$ and 50.

The two systems of simultaneous equations for the coefficient B_n, C_n and A_n, D_n are solved by using the Gaussian elimination method (IBM-SSP-DGELG) on IBM-360/67 with a relative tolerance of 10^{-8} . The results and the related constants are listed in Tables 3-6. The series expansion coefficients with $N = 20$ are also obtained by using a method for nonorthogonal series described by Kantorovich and Krylov [11] but it yields negligible improvement in the accuracy of the series expansion coefficients. After obtaining the coefficients, the matching conditions at $x = 0$ given by equation (4) are checked. The first matching condition $\theta_1 = \theta_2$ is satisfied very well and three significant figures agree excluding the points near the upper and lower plates. The second matching condition $\partial\theta_1/\partial x = \partial\theta_2/\partial x$ is met satisfactorily but the agreement is one order lower. It is expected that the matching conditions at $z = \pm 1$ will not be satisfied in view of the discontinuity of the boundary conditions at $x = 0$. It is also found that four significant figures agree for bulk temperatures at $x = 0$.

2.2.3 Local Nusselt Numbers

The local Nusselt numbers Nu_1 and Nu_2 at the lower and upper plates defined by the following equations for the case of heating from below ($T_1 > T_2$) are of practical interest in this study.

$$Nu_1 = \frac{h_1(4\ell)}{k} = \frac{(4\ell)}{k} \frac{q_1}{(T_1 - T_b)} = \frac{4}{1 + \theta_b} \left(\frac{\partial \theta_2}{\partial z} \right)_{z=-1} \quad (19)$$

$$Nu_2 = \frac{h_2(4\ell)}{k} = \frac{(4\ell)}{k} \frac{q_2}{(T_b - T_2)} = \frac{4}{1 - \theta_b} \left(\frac{\partial \theta_2}{\partial z} \right)_{z=1} \quad (20)$$

where the bulk temperature θ_b is

$$\theta_b = \frac{\int_{-1}^1 \theta u dz}{\int_{-1}^1 u dz} \quad (21)$$

Substituting equation (6) into equations (19) to (21) yields,

$$Nu_{2,1} = \frac{4+4 \left[\sum_{n=1}^{\infty} C_n (dR_n(1)/dz) \exp(-\beta_n^2 x) + \sum_{n=1}^{\infty} D_n (dZ_n(1)/dz) \exp(-\gamma_n^2 x) \right]}{1+(3/2) \sum_{n=1}^{\infty} C_n \exp(-\beta_n^2 x) \left[(dR_n(1)/dz) / \beta_n^2 + (8\beta_n / 3Pe)^2 \int_0^1 R_n(z) dz \right]} \quad (22)$$

$$\theta_b = - \frac{3}{2} \sum_{n=1}^{\infty} C_n \exp(-\beta_n^2 x) \left[\frac{dR_n(1) dz}{\beta_n^2} + \left(\frac{8\beta_n}{3Pe} \right)^2 \int_0^1 R_n(z) dz \right] \quad (23)$$

The bulk temperature in the adiabatic section is

$$\theta_{1b} = \theta_0 + \frac{3}{2} \left(\frac{8}{3Pe} \right)^2 \sum_{n=1}^{\infty} B_n \alpha_n^2 \exp(\alpha_n^2 x) \int_0^1 Y_n(z) dz \quad (24)$$

One may note that the case $Pe \rightarrow \infty$ corresponds to that of no axial conduction.

2.3 Results and Discussion

The profiles of the first eight eigenfunctions only for Y_n , R_n , Z_n and F_n are shown in Figs. 2 to 5 for $Pe = 1$. The developing temperature profiles, $\phi_\theta = \frac{1}{2}(1 - \theta)$, versus the transformed coordinate $\bar{z} = (z + 1)/2$ in both upstream and downstream regions are presented in Figs. 6 to 8 for $Pe = 1, 5$ and 10 , respectively, with $\theta_0 = 1$. In Fig. 6 ($Pe = 1$), the temperature profile is seen to be flat upstream of $x = -4$ ($\phi_\theta = 0.27$). At $x = -30$, one obtains $\phi_\theta = 0.027$. This suggests that at $Pe \approx 1$ the axial heat conduction effect is felt throughout a rather extensive upstream region. For the upstream region $x \leq -4$, the effect of the lower plate $x \geq 0$ at temperature T_1 disappears completely and the transverse conduction term $\partial^2 \theta / \partial z^2$ in energy equation (1) can be neglected entirely. Thus, at $Pe = 1$ the region $-30 \leq x \leq -4$ can be regarded to be a pure axial conduction region. The fully developed temperature profile is seen to be attained at $x \approx 6$. In the region $-0.1 \leq x \leq 0.1$, the change of the temperature profile is rather gradual. In

Fig: 6, the axial distributions of the wall temperatures, in the adiabatic region are also of interest.

The effect of the axial heat conduction on developing temperature profiles in both adiabatic and heated regions persists for $Pe = 5$ and 10 as shown in Figs. 7 and 8, respectively. It is also seen that the uniform entrance fluid temperature $\phi_{\theta} = 0$ is practically reached at $\bar{x} = -2$ and -1 for $Pe = 5$ and 10 , respectively. At $Pe = 50$ shown in Fig. 9, the axial heat conduction effect is confined to a rather small region $0 \leq z \leq 0.3$, $-0.05 \leq x \leq 0$. The upstream heat penetration in the region near the upper plate $0.6 \leq z \leq 1.0$, $-10^{-3} \leq x \leq 10^{-3}$, is apparently not a physical solution and the temperature field is $\phi_{\theta} = 0$ there. The imposition of the discontinuous boundary conditions $\partial\phi_{\theta 1}(0,1)/\partial z = 0$ and $\phi_{\theta 2}(0,1) = 0$ coupled with the uniform entrance temperature condition $\phi_{\theta 1} = 0$ at $x = -\infty$ for $0.6 \leq z \leq 1.0$ is apparently the source of difficulty. The mathematical conditions mentioned are incompatible with the physical situation and one thus concludes that the mathematical solution fails for the small region $0.6 \leq z \leq 1.0$, $-10^{-3} \leq x \leq 10^{-3}$. From practical viewpoint, it is seen that the axial heat conduction is not significant at $Pe > 50$. It should be pointed out that the above difficulty arises only when the boundary conditions at lower and upper plates are different. This also serves to emphasize the difference between the present problem and that of published work [4].

For the present problem, the matching of the temperatures and axial temperature gradients at $x = 0$ is critical and the results for ϕ_θ at $x = 0$ are shown in Fig. 10 for $Pe = 1, 5, 10$ and 50 . The matching is satisfied very well for $Pe = 1, 5$ and 10 but the numerical result for $Pe = 50$ near the upper plate is not a physical solution. Physically, one knows that the upstream and downstream temperatures, $\phi_{\theta 1}$ and $\phi_{\theta 2}$, should be continuous at $x = 0$ including upper and lower plates. Fig. 10 shows that at the lower plate $z = 0$, the temperature discontinuity for ϕ_θ increases with the increase of Peclet number. On the other hand, at the upper plate $z = 1$, the agreement for $\phi_{\theta 1}$ and $\phi_{\theta 2}$ is better for $Pe = 10$ than for $Pe = 1$. At $Pe = 50$, the discontinuity for ϕ_θ at $z = 1$ is clearly the source of difficulty since the series solution for ϕ_θ must be continuous and $\phi_\theta = 0$ for $0.2 \leq z \leq 1.0$. The mathematical difficulty near the upper plate at $x = 0$ for $Pe = 50$ can also be explained from the energy equation (1). When the Peclet number is large, the concept of thermal boundary layer is applicable and $\partial\theta/\partial x$ and $\partial^2\theta/\partial x^2$ are zero in the neighbourhood of the upper plate near $x = 0$. As a result, one obtains $\partial^2\theta/\partial z^2 = 0$ only and the transverse conduction term cannot be balanced by the convective term. One notes that the above situation does not occur near the lower plate where one has thermal boundary layer. The above explanation represents another source of difficulty besides the thermal boundary conditions at $x = 0$. Further increase of the

number of series coefficients to $n = 24$ does not improve the numerical results for $Pe = 1, 5, 10$ and 50 near $x = 0$. It is found that with $n = 26$, the Gram determinant [4] $\Delta_n \rightarrow 0$ for the odd eigenfunctions Z_n and the series coefficients cannot be obtained. It is also found that with $n = 26$, the eigenfunction Z_n is of the order 10^{-3} (see also Fig. 4). It is thus seen that as n increases Z_n decreases.

The effect of Peclet number on the axial distribution of the bulk temperature is shown in Fig. 11 and the numerical results are listed in Table 7. At $Pe = 1$, the axial heat conduction effect is quite appreciable but at $Pe = 50$ the effect may be practically negligible. The upstream and downstream development lengths for attaining the asymptotic values $\theta_b = 1$ and 0 , respectively, depend on Peclet number.

The local Nusselt number results at the lower and upper plates are shown in Fig. 12 for $Pe = 1, 5, 10, 50$ and with $\theta_0 = 1$ and the numerical results are listed in Table 8. The behavior of the local Nusselt number at lower plate Nu_1 is generally similar to that reported in references [4, 10]. Near $x = 0$, both Nu_1 and Nu_2 become quite uniform with the decrease of Peclet number. When the axial heat conduction is negligible ($Pe \rightarrow \infty$), $Nu_1 \rightarrow \infty$ as $x \rightarrow 0$ and Nu_2 is zero throughout some thermal-entry region near $x = 0$. The case of $Pe = \infty$ is also discussed in reference [7]. It is seen that both Nu_1 and Nu_2 for various Peclet numbers approach the same fully developed value 4.0 and the thermal entrance length increases with the decrease of

Peclet number.

2.4. Concluding Remarks

1. For $\theta_0 = 1$, the present physical model is not applicable when $Pe > 50$ and the classical Graetz formulation neglecting axial heat conduction should be used. It appears that the mathematical difficulty arises as the physical problem changes from elliptical problem to parabolic problem. When $Pe < 50$, the axial heat conduction effect on bulk temperature and local Nusselt numbers is appreciable. The numerical results for $\theta_0 \neq 1$ can also be obtained without difficulty.

2. The even eigenvalues α_n, β_n check very well with those reported in reference [4] and can also be used in ascertaining the eigenvalue spectrum. The characteristic equations (7) and (9) suggest that for $Pe \leq 1$, the approximate eigenvalues for α_n and β_n can be obtained by the following relations.

$$\alpha_n^2 = \frac{8Pe}{3} (n - 1)\pi, \quad n = 2, 3, \dots,$$

$$\beta_n^2 = \frac{8Pe}{3} (n - \frac{1}{2})\pi, \quad n = 1, 2, 3, \dots$$

Generally, the above approximations improve with the increase of n . It is found that the above approximations can still

be used for $Pe = 5$ but the accuracy decreases by one order of magnitude as compared with the case of $Pe = 1$. It is also found that $\epsilon_n = (\alpha_n + \alpha_{n+1})/2$ and $\gamma_n = (\beta_n + \beta_{n+1})/2$ for any Pe . For $Pe = \infty$, the eigenvalues β_n, γ_n from reference [7] are used.

3. The present numerical results as shown in Fig. 10 clearly bring out the nature of the analytical solution for the present elliptic problem with $Pe = 50$. The local mathematical difficulty for $Pe = 50$ near the upper plate at $x = 0$ is noteworthy and the phenomenon does not appear to have been pointed out in the past. At $Pe = 50$, the difficulty is confined to the local region near $x = 0$ and $z = 1$ but the bulk temperature appears to be reasonable as shown in Fig. 11.

4. For low Peclet number flow regime, the axial heat conduction can cause a considerable increase in thermal development lengths for both upstream and downstream regions.

5. For low Peclet number flow ($Pe < 50$), one can clearly identify three different regimes, namely pure axial heat conduction, developing and fully developed regions, for the thermal entrance region problem. When heating is from below ($T_1 > T_2$), thermal instability problem concerned with the onset of secondary flow in the form of longitudinal vortices or transverse rolls arises at a certain $\Delta T = T_1 - T_2$. The instability problem is studied in Chapter III, and the present solution serves as a basic flow solution.

CHAPTER III

AXIAL HEAT CONDUCTION EFFECTS ON THERMAL INSTABILITY OF HORIZONTAL PLANE POISEUILLE FLOWS HEATED FROM BELOW

A linear stability analysis is used to study the effect of axial heat conduction on the onset of instability for longitudinal and transverse vortex disturbances for plane Poiseuille flow in the thermal entrance region of a horizontal parallel-plate channel heated from below with a constant temperature difference between two plates. The basic flow solution for temperature (Graetz problem) incorporates axial heat conduction effect and the fluid temperature is taken to be uniform at far upstream location $\bar{x} = -\infty$ to allow for the upstream heat penetration through thermal entrance $\bar{x} = 0$. Numerical results for critical Rayleigh numbers are obtained for entrance temperature parameter $\theta_0 = 1$ and Peclet numbers 1, 5, 10, 50. It is found that the transverse vortex disturbances are preferred over the longitudinal vortex disturbances for $Pe \leq 1$ and $Pr \geq 1$ (low Re) in the developing regions upstream and downstream of the thermal entrance. For other conditions, the longitudinal rolls have priority of occurrence. The Prandtl number effect on the onset of the longitudinal vortices is clarified.

Nomenclature

A_n, B_n, C_n, D_n	=	coefficients of infinite series in eqs. (5) and (6)
a_1, a_2, a	=	wave numbers in x and y directions and $(a_1^2 + a_2^2)^{1/2}$
c	=	amplification or damping factor, $c = 0$ at onset of instability
D	=	d/dz
Gr	=	Grashof number, $g\beta(\Delta T)L^3/\nu^2$
g	=	gravitational acceleration
i	=	$(-1)^{1/2}$
L, ℓ	=	height of channel and $L/2$
P, P_b	=	fluid pressure ($P_b + P'$) and basic flow pressure
Pe	=	Peclet number, $4 U_m \ell / \alpha = RePr$
Pr	=	Prandtl number, ν / α
P'	=	dimensionless perturbation pressure, $P' / (\rho \nu^2 / L^2)$
Ra	=	Rayleigh number, $PrGr$
Re	=	Reynolds number, $4 U_m \ell / \nu$
T, T_b, T_m, T_0	=	fluid temperature ($T_b + \theta'$), basic flow temperature, $(T_1 + T_2)/2$ and uniform upstream temperature

- T_1, T_2 = constant lower and upper plate temperatures
 U_b, U_m, u_b = axial and mean velocities and (U_b/U_m)
of basic flow
 U', V', W' = disturbance velocity components
 u, v, w = dimensionless perturbation velocity
components, $(U', V', W')/\nu/L$
 X, Y, Z = Cartesian coordinates with origin at
lower plate
 X', Z' = coordinates with origin at center of
channel
 x, y, z = $(X, Y, Z)/L$
 x', z' = $(X'/(3/8)\ell Pe, Z'/\ell)$
 \bar{x}, \bar{z} = transformed coordinates, $(x/(3Pe/16), z)$
 Y_n, R_n, F_n, Z_n = eigenfunctions
 α = thermal diffusivity
 $\alpha_n, \beta_n, \epsilon_n, \gamma_n$ = eigenvalues
 ϵ = coefficient of thermal expansion
 e = dimensionless disturbance temperature,
 $e'/\Delta T$
 θ_b, θ_0 = dimensionless temperature and uniform
entrance temperature, $(T_b - T_m)/(T_2 - T_m)$
and $(T_0 - T_m)/(T_2 - T_m)$
 ν = kinematic viscosity

ρ = density

ϕ_u, ϕ_θ = dimensionless basic velocity and temperature profiles, $(1/2)u_b = 3(z - z^2)$,
 $\theta_b = (1 - \theta_b)/2$

$\Delta T = (T_1 - T_2)$

Superscripts and Subscripts

' = perturbation quantity

+ = amplitude of disturbance quantity

* = transformed perturbation variable or critical value

b = basic flow quantity in unperturbed state

1,2 = upstream and downstream regions

3.1 Introduction

Thermal instability of a plane Poiseuille flow concerned with the onset of a secondary flow in the form of longitudinal vortex rolls in the thermal entrance region of horizontal parallel-plate channels heated from below was studied theoretically by Hwang and Cheng [1] considering the axial heat conduction term in the energy equation for basic flow. Recent studies by Hennecke [2] and Hsu [3] on Graetz problem with axial heat conduction effects show clearly that the usual thermal condition of uniform entrance fluid temperature at $X = 0$ used in the classical Graetz problem is unrealistic for low Peclet number flow regime ($Pe \leq 50$) because of the upstream heat penetration through thermal entrance $X = 0$ and the fluid temperature must be taken to be uniform far upstream at $X = -\infty$. In view of the predominance of the axial heat conduction effects near the thermal entrance $X = 0$ for very low Peclet number flows, the instability analysis [1] based on uniform entrance temperature at $X = 0$ for basic flow solution must be regarded as an approximate one when Peclet number is very small.

A deductive analysis of the Graetz problem by Ostrach [4] clarifies the importance of the axial heat conduction term in the energy equation. However, for very low Peclet number flow regime, the problem is of elliptic type and the concept of the thermal boundary layer is not applicable. Consequently, the thermal boundary-layer thickness cannot be used as a characteristic length in normalizing the equa-

tion. An explicit criterion for the neglect of viscous dissipation is also clearly given in [4]. When the Reynolds number is very small, a question on the priority of the occurrence of transverse rolls [5,6,7] over longitudinal rolls arises. Recently, Kamotani and Ostrach [8] determined experimentally the critical Rayleigh numbers for thermally-developing laminar channel flow and compared the experimental results with the results from linear stability theory [1]. A difference as large as an order of magnitude between the two results is observed but apparently this is somewhat similar to the discrepancy between the experimental [9] and theoretical [10-13] results for longitudinal vortex instability of natural convection flow on inclined surfaces. The difference can be attributed to the infinitesimal disturbances in theory and the measurable disturbances in experiment.

The purpose of this investigation is to study the effects of axial heat conduction on thermal instability of a plane Poiseuille flow between two horizontal flat plates where the lower plate is maintained at a higher constant temperature T_1 ($\Delta T \geq 0$) and the upper plate at T_2 which is identical with the uniform entrance fluid temperature T_0 at far upstream ($X = -\infty$). The mathematical formulation for the basic flow in the thermal entrance region of the parallel-plate channel heated from below is similar to that used by Hennecke [2] and Hsu [3] which is considered to be the most rigorous analysis of the Graetz problem.

The onset of convective instability for both longitudinal and transverse vortex rolls in the low Peclet number flow regime is studied by using linear stability theory.

3.2 Temperature Solutions for Basic Flow

Neglecting the viscous dissipation effects, the governing equations in dimensionless form for the thermal entrance region problem (see Fig. 1) with axial heat conduction are [3]

$$\frac{2}{3} u_b \frac{\partial \theta_b}{\partial x'} = \frac{\partial^2 \theta_b}{\partial z'^2} + \left(\frac{8}{3Pe}\right)^2 \frac{\partial^2 \theta_b}{\partial x'^2} \quad (1)$$

$$\theta_{b1}(-\infty, z') = \theta_0, \quad \partial \theta_{b1}(x', 1) / \partial z' = \partial \theta_{b1}(x', -1) / \partial z' = 0$$

$$\text{for } -\infty < x' \leq 0 \quad (2)$$

$$\theta_{b2}(\infty, z') = \theta_f, \quad \theta_{b2}(x', 1) = 1, \quad \theta_{b2}(x', -1) = -1$$

$$\text{for } 0 \leq x' < \infty \quad (3)$$

$$\theta_{b1}(0, z') = \theta_{b2}(0, z'), \quad \partial \theta_{b1}(0, z') / \partial x' = \partial \theta_{b2}(0, z') / \partial x'$$

$$\text{at } x' = 0 \quad (4)$$

where the dimensionless variables are defined in Nomenclature

and $u_b = (3/2)(1 - z'^2)$ for a plane Poiseuille flow.

Following the procedures outlined in [3,14], the temperature solutions θ_{b1} and θ_{b2} in the adiabatic and heated regions, respectively, satisfying the conditions at $x' = \pm\infty$ can be written as,

$$\theta_{b1}(x', z') = \theta_0 + \sum_{n=1}^{\infty} B_n Y_n(z') \exp(\alpha_n^2 x') + \sum_{n=1}^{\infty} A_n F_n(z') \exp(-\beta_n^2 x'), \quad -\infty < x' < 0 \quad (5)$$

$$\theta_{b2}(x', z') = z' + \sum_{n=1}^{\infty} C_n R_n(z') \exp(-\beta_n^2 x') + \sum_{n=1}^{\infty} D_n Z_n(z') \exp(-\gamma_n^2 x'), \quad 0 \leq x' < \infty \quad (6)$$

where α_n , β_n and Y_n , F_n are the even and odd eigenvalues and eigenfunctions, respectively, for the adiabatic region. Similarly, β_n , γ_n and R_n , Z_n are the even and odd eigenvalues and eigenfunctions, respectively, for the heated region. The details of the solution method and the computed eigenvalues and eigenfunctions as well as the series expansion coefficients for the case $\theta_0 = 1$ are given in Chapter II. A fourth-order Runge-Kutta method [15] using two hundred equal steps is employed to obtain the eigenvalues and eigenfunctions from the numerical solution of the characteristic

equations and their boundary conditions. The series coefficients are calculated by matching both the temperatures and the axial temperature gradients at $x = 0$ after constructing orthonormal functions from the nonorthogonal eigenfunctions [3]. In this study, the infinite series are truncated at $n = 12$ and 8 for $Pe = 1, 5$ and $Pe = 10, 50$, respectively. For the instability problem, it is more convenient to shift the coordinate origin to the lower plate as shown in Fig. 1. The basic temperature profile now becomes $T_b = (1 - y/b)/2$.

2.3. Perturbation Equations

The derivation of the perturbation equations is based on the method of small disturbances (a linearization about the basic flow) using the Boussinesq approximation. Introducing the sum of the basic flow and the disturbance flow as $U = U_b + U'$, $V = V'$, $W = W'$, $T = T_b + \theta'$ and $P = P_b + P'$, subtracting out the basic flow equations from the conservation equations for mass, momentum and energy, one obtains the following disturbance equations after neglecting non-linear terms.

$$\frac{\partial U'}{\partial X} + \frac{\partial V'}{\partial Y} + \frac{\partial W'}{\partial Z} = 0 \tag{7}$$

$$\rho \frac{\partial U'}{\partial X} + W' \frac{\partial U_b}{\partial X} = - \frac{1}{\rho} \frac{\partial P'}{\partial X} + \nu \nabla^2 U' \tag{8}$$

$$U_b \frac{\partial V'}{\partial X} = - \frac{1}{\rho} \frac{\partial P'}{\partial Y} + \nu \nabla^2 V' \quad (9)$$

$$U_b \frac{\partial W'}{\partial X} = - \frac{1}{\rho} \frac{\partial P'}{\partial Z} + \nu \nabla^2 W' + g \beta \theta' \quad (10)$$

$$U_b \frac{\partial \theta'}{\partial X} + U' \frac{\partial T_b}{\partial X} + W' \frac{\partial T_b}{\partial Z} = \alpha \nabla^2 \theta' \quad (11)$$

where $\nabla^2 = \partial^2/\partial X^2 + \partial^2/\partial Y^2 + \partial^2/\partial Z^2$ and the disturbances are taken to be independent of time [1,8,10].

After introducing the dimensionless variables, $(x,y,z) = (X,Y,Z)/L$, $(u,v,w) = (U',V',W')/(v/L)$, $p = P'/(v^2/L^2)$, $\theta = \theta'/(AT)$ and the parameter $Gr = g\beta(\Delta T)L^3/v^2$, the disturbance equations become

$$\frac{\partial u}{\partial x} + \frac{\partial v}{\partial y} + \frac{\partial w}{\partial z} = 0 \quad (12)$$

$$Re\phi_u \frac{\partial u}{\partial x} + Re \frac{d\phi_u}{dz} w = - \frac{\partial p}{\partial x} + \nabla^2 u \quad (13)$$

$$Re\phi_u \frac{\partial v}{\partial x} = - \frac{\partial p}{\partial y} + \nabla^2 v \quad (14)$$

$$Re\phi_u \frac{\partial w}{\partial x} = - \frac{\partial p}{\partial z} + \nabla^2 w + Gr\theta \quad (15)$$

$$Re\phi_u \frac{\partial \theta}{\partial x} + u \frac{\partial \phi_\theta}{\partial x} + w \frac{\partial \phi_\theta}{\partial z} = \frac{1}{Pr} \nabla^2 \theta \quad (16)$$

where $\phi_u = 3z(1-z)$, $\phi_{11} = (T_b - T_2)/\Delta T = (1 - \phi_b)/2$ and the operator is understood to be $\nabla^2 = \partial^2/\partial x^2 + \partial^2/\partial y^2 + \partial^2/\partial z^2$. The dependent variables u , v and p can be eliminated from the continuity and three momentum equations and one obtains a single equation as

$$\text{Re} \phi_u \frac{\partial}{\partial x} (\nabla^2 w) - \text{Re} \frac{d^2 \phi_u}{dz^2} \frac{\partial w}{\partial x} = \nabla^2 \nabla^2 w + \text{Gr} \nabla_1^2 \theta \quad (17)$$

where $\nabla_1^2 = \partial^2/\partial x^2 + \partial^2/\partial y^2$ and $\nabla^2 = \nabla_1^2 + \partial^2/\partial z^2$.

A separable solution for w and θ may be sought in the following form [1].

$$f(x, y, z) = f^+(z) \exp[cx + i(a_1 x + a_2 y)] \quad (18)$$

where c is the amplification factor and the wave numbers a_1 and a_2 are real. Confining attention to neutral stability, one has $c = 0$. After substituting equation (18) for the disturbances w and θ , respectively, into equations (17) and (16), one obtains

$$\begin{aligned} (D^2 - a^2)^2 w^+ - ia_1 \text{Re} \phi_u (D^2 - a^2) w^+ + ia_1 \text{Re} (d^2 \phi_u / dz^2) w^+ \\ = \text{Gr} a^2 \theta^+ \end{aligned} \quad (19)$$

$$(D^2 - a^2)\theta^+ - ia_1 Pe \phi_u \theta^+ = Pr [u^+ \partial \phi_u / \partial x + w^+ \partial \phi_u / \partial z] \quad (20)$$

where $a^2 = a_1^2 + a_2^2$ and $D = d/dz$. The above two disturbance equations involve three unknowns and u remains to be specified. The following two cases [6] are of interest in this study:

1. For longitudinal rolls ($a_1 = 0$), the x-momentum equation (13) gives

$$(D^2 - a^2)u^+ = Re(d\phi_u/dz)w^+ \quad (21)$$

It is noted that at neutral stability the x-dependence for the disturbance quantities can be neglected and one has $\partial p / \partial x = 0$.

2. For transverse rolls ($a_2 = 0$), the continuity equation (12) gives [6]

$$u^+ = i Dw^+ / a_2 \quad (22)$$

At this point, it is more convenient to introduce the transformations, $x = (3Pe/16)\bar{x}$, $z = \bar{z}$, $u^+ = Re u^*$, $w^+ = w^*$, $\theta^+ = Pr \theta^*$, $u^+ = Re u^*$, $Ra = GrPr$ and one obtains:

1. Longitudinal rolls

$$(D^2 - a_2^2)^2 w^* = Ra a_2^2 \theta^* \quad (23)$$

$$(D^2 - a_2^2)u^* = (d\psi_u/d\bar{z})w^* \quad (24)$$

$$(D^2 - a_2^2)\theta^* = (16/3Pr)u^* \partial\phi_0/\partial\bar{x} + w^* \partial\phi_0/\partial\bar{z} \quad (25)$$

2. Transverse rolls

$$\begin{aligned} (D^2 - a_1^2)^2 w^* - ia_1 Re \phi_u (D^2 - a_1^2) w^* + ia_1 Re (d^2 \psi_u / d\bar{z})^2 w^* \\ = Ra a_1^2 \theta^* \end{aligned} \quad (26)$$

$$u^* = (i/a_1 Re) Dw^* \quad (27)$$

$$(D^2 - a_1^2)\theta^* - ia_1 Pe \phi_u \theta^* = (16/3Pr)u^* \partial\phi_0/\partial\bar{x} + w^* \partial\phi_0/\partial\bar{z} \quad (28)$$

The boundary conditions at the rigid and highly conductive walls applicable to the above two types of disturbances are

$$w^* = Dw^* = u^* = \theta^* = 0 \quad \text{at } \bar{z} = 0 \text{ and } 1 \quad (29)$$

In this study, the oblique modes ($a_1 \neq 0, a_2 \neq 0$) are not considered [6] since the above two modes are observed experimentally. For transverse rolls, the disturbance u^* may be eliminated by substituting equation (27) into equation (28) and only the real part of the disturbance equations

is considered to have physical significance. It is seen that equation (26) is the Orr-Sommerfeld type equation and is coupled with the energy equation (28).

3.4 Method of Solution

Considering the expressions for the basic temperature profiles θ_{b1} and θ_{b2} , it is obvious that an analytical solution of the present characteristic value problem is not practical. An iterative technique using the higher order finite difference scheme [16] is used for the simultaneous solution of the coupled disturbance equations [1]. The details of the numerical solution method are in Appendix I and only an outline of the iterative procedure is presented here. Given the basic profiles ϕ_u and ϕ_θ for the specified values of Pe and θ_0 , the iterative procedure for the case of the longitudinal rolls consists of the following main steps:

1. At a given axial position \bar{x} , a value of the wave number $a_2 = 2.5$ (say) is selected and an eigenvalue Ra is assumed. The disturbance velocity w_k^* is taken in the form of $w_k^* = 2(1 - k/M)$, $k = 2, 3, \dots, M$ and $Ra = 1708$ is used in this study.

2. The finite-difference solution of equation (24) gives u_k^* .

3. After knowing w_k^* and u_k^* , the energy equation (25) can be solved to obtain θ_k^* .

4. New values for w_k^* can be found from the finite-

difference solution of equation (23).

5. An improved eigenvalue $(Ra)_{new}$ can be computed by using the following equation [17].

$$(Ra)_{new} = (Ra)_{old} \left[\sum_k (w_k^*)_{old}^2 \right]^{1/2} / \left[\sum_k (w_k^*)_{new}^2 \right]^{1/2} \quad (30)$$

The magnitude of w_k^* is readjusted by the following equation in order to return to the original order of magnitude for computation.

$$w_k^* = (w_k^*)_{new} (Ra)_{new} / (Ra)_{old} \quad (31)$$

6. The steps (2) to (4) are repeated until the following preassigned convergence criterion is satisfied.

$$e = \frac{\sum_k |(w_k^*)_{new} - (w_k^*)_{old}|}{\sum_k |(w_k^*)_{new}|} \leq 10^{-6} \quad (32)$$

7. The minimum Rayleigh number is then searched. It is found that only 3 to 5 iterations are required to satisfy the above criterion and five significant figures are correct for critical Ra .

The numerical method of solution for the case of transverse rolls is generally similar to that discussed above with the following differences:

1. The disturbance quantities w^* , u^* and θ^* are now complex.

2. The initial values for w_k^* are taken as $w_k^* = 2(1 - k/M) + 2i(1 - k/M)$, $k = 2, 3, \dots, M$.

3. A new and improved eigenvalue can be calculated by using the following equation [18].

$$(Ra)_{\text{new}} = (Ra)_{\text{old}} \left[\frac{\sum_k (w_k^*)_{\text{old}} (\bar{w}_k^*)_{\text{old}}}{\sum_k (w_k^*)_{\text{new}} (\bar{w}_k^*)_{\text{new}}} \right]^{1/2} \quad (33)$$

where (\bar{w}_k^*) is the conjugate of the complex disturbance (w_k^*) .

4. The convergence criterion based on equation (32) is $\leq 10^{-3}$. The number of iterations required to satisfy the above condition ranges from 20 to 25 and four significant figures are found to be correct for critical Ra at the onset of transverse rolls.

3.5 Results and Discussion

The critical Rayleigh numbers at the onset of secondary motion are of primary interest in this study. The graphical results are presented in Fig. 2 to 8 and the numerical results are summarized in Tables 1 to 5 for the case $\theta_0 = 1$. The effects of Prandtl number on the onset of longitudinal vortex rolls in both the upstream and downstream regions are shown in Fig. 2 to 5 for $Pe = 1, 5, 10$ and 50, respectively.

For $\theta_0 = 1$ and $Pe = 1$, the instability results for

$Pr = 0.7, 1, 10, 100$ and ϵ are practically identical and the critical Rayleigh number decreases monotonically from the asymptotic value of $Ra^* = \infty$ at $\bar{x} = -6$ to $Ra^* = 1708$ at $\bar{x} = 3.0$ for a linear basic temperature profile. The independence of the critical Rayleigh number Ra^* on Prandtl number for $Pr \geq 0.7$ in the case of $Pe = 1$ can be explained from perturbation equation (25). It is found that when $Pe = 1$, the relative magnitude of the ratio $R = (\partial\theta_0/\partial\bar{x}) / (\partial\theta_0/\partial\bar{z})$ is less than 10^{-3} and consequently the forcing term $(16/3Pr)(\partial\theta_0/\partial\bar{x})u^*$ on the right-hand side of equation (18) can be neglected in comparison with the term $(\partial\theta_0/\partial\bar{z})w^*$ for the range $Pr = 0.7$ to ∞ . Thus, the coupled effect of the vertical basic temperature gradient $\partial\theta_0/\partial\bar{z}$ and the vertical velocity disturbance w^* dominates. On the other hand, when $Pe = 5$ and 10 , the ratio R is found to be less than 10^{-2} and 10^{-1} , respectively. It is thus seen that the instability result is independent of Prandtl number when $Pr \geq 10$ for $Pe = 5$ and $Pr \geq 100$ for $Pe = 10$. The above argument assumes that the axial and vertical basic temperature gradients, $\partial\theta_0/\partial\bar{x}$ and $\partial\theta_0/\partial\bar{z}$ are of the same order of magnitude which is verified by the numerical results of Chapter II. From the foregoing discussion, it is also clear that the role of Prandtl number becomes increasingly important as the Prandtl number decreases for a given Peclet number. When Pr is small, the term $(16/3Pr)u^*\partial\theta_0/\partial\bar{x}$ also destabilizes the flow. As is seen from Fig. 2 to 4, a local minimum for Ra^* exists when Prandtl number is small. This means

that when Prandtl number is small, the region near the thermal entrance $\bar{x} = 0$ is more unstable than the fully developed region and the practical implications are believed to be important for liquid metals. Noting that the basic temperature profile θ_0 is a function of Peclet number only, one sees that the effect of Prandtl number appears through the disturbance equation (25) only:

The instability results for $Pe = 50$ are shown in Fig. 5 where the unpublished results of the earlier analysis [1] based on the assumption that the fluid temperature is uniform at the thermal entrance $\bar{x} = 0$ are also plotted for comparison. One should note that the simplified model [1] predicts $Ra^* = \infty$ at $\bar{x} = 0$ whereas the present model predicts a finite value for Ra^* at $\bar{x} = 0$. At $Pe = 50$, the concept of thermal boundary layer is applicable (Chapter II) and the lower Ra^* at a given \bar{x} from [1] for a given Pr can be attributed to the larger unstable thermal boundary layer thickness caused by the somewhat artificial absence of the upstream heat penetration through $\bar{x} = 0$. The effect of the axial heat conduction is seen to decrease the thermal boundary layer thickness and the axial temperature gradient $\partial\theta_0/\partial\bar{x}$. One should note that at $Pe = 50$, the lower limit for Pr exists because of the critical Reynolds number $Re = 14,170$. At $Pr = 0.1$, the entrance region is seen to be more unstable than the fully developed region.

In order to critically examine the effect of upstream heat conduction on critical Ra^* , the instability results

for $Pr = 0.7, 10, 100$ and $Pe = 5$ are compared against the unpublished results of the earlier study [1] neglecting the upstream heat penetration through $\bar{x} = 0$ in Fig. 6. At $Pe = 5$, the earlier model is apparently inadequate in predicting Ra^* . It is noted that the trend of the Prandtl number effect on Ra^* between the present and earlier analyses for $Pe = 50$ (see Fig. 5) and $Pe = 5$ is just opposite. This is caused by the fact that at $Pe = 50$, the problem is basically parabolic and the concept of thermal boundary layer is applicable whereas at $Pe = 5$, the problem is elliptic and the heat from the lower plate already penetrates to the upper plate at $\bar{x} = 0$. It is then clear that the larger unstable fluid layer near $\bar{x} = 0$ from the present physical model leads to the considerably lower Ra^* .

The effect of Peclet number on Ra^* for $Pr = 0.7$ (air) is shown in Fig. 7. The Peclet number effect on Ra^* in the upstream region is seen to be opposite to that in the downstream region. The lower Ra^* for $Pe = 1$ in the adiabatic region is due to the larger unstable fluid layer caused by the axial heat conduction. The developing temperature profiles shown in Chapter II clearly confirm the above statement. The instability results for $Pr = 10$ (water) are also shown in Fig. 8. The thermal entrance length for $Pe = 1$ is longer than those of $Pe = 5, 10, 50$ and correspondingly the asymptotic value $Ra^* = 1708$ for a fully developed basic flow with a linear temperature profile is approached at a farther downstream location.

The case of transverse rolls is of special interest in this study and the numerical results for $Pe = 1$ and $Pr = 1, 100$ are listed in Table 5. The graphical results are presented in Fig. 9 where the instability results for the case of longitudinal vortex rolls are also plotted for comparison. It is seen that the onset of the transverse rolls has priority over that of the longitudinal rolls in the upstream region as well as part of the downstream region ($x = 1.2$). Note that the case of $Pr = 100$ is more unstable than that of $Pr = 1$ for transverse rolls but the opposite is true for longitudinal rolls. It is also found that for $Pe = 1, Pr \leq 0.1$ the transverse rolls have no priority over the longitudinal rolls. Similarly, numerical results reveal that Ra^* for transverse rolls is higher than that for longitudinal rolls at $\bar{x} = 0$ for $Pe \geq 5$. It is thus concluded that the onset of the transverse rolls has priority over that of the longitudinal rolls only when $Pe > 1$ and $Pr \geq 1$ (or small Re) and it occurs in the upstream and downstream regions near the thermal entrance $\bar{x} = 0$. For fully developed region, the longitudinal rolls appear to have priority but the difference in Ra^* is so small that the transverse rolls may occur under certain conditions.

For a given Pe , as $Pr \rightarrow \infty$ one obtains $Re \rightarrow 0$. The perturbation equations for transverse rolls in the fully developed region then become:

$$(D^2 - a_1^2) \bar{w} = \dots \quad (34)$$

$$(D^2 - a_1^2)^2 \theta^* = -i a_1 Pe \theta^* \frac{w^* \partial \theta_0 / \partial z}{\dots} \quad (35)$$

where $a_1^2 = -1$. The calculation for $Pe = 1$ gives $Ra^* = 1717.06$ and $a_1^* = 3.117$. The fact that Ra^* is larger than the value of 1708 for longitudinal rolls suggests that the term involving Pe in equation (35) may have a stabilizing effect.

The physical reasons for the priority of the "transverse-vortex disturbances" over the "longitudinal vortex disturbances" under the conditions stated earlier are not immediately clear from the study of the disturbance equations and a consideration of the energy exchange between the main flow and the perturbation. However, it appears that when Re is large the transverse rolls tend to be washed out. In addition, one notes that the developing basic temperature profiles show negative axial temperature gradient near upper plate ($\bar{z} = 0.6 \sim 1.0$) for $x > -0.1$ at $Pe = 1$ (Chapter II). At $Pe = 5$, the region of negative axial temperature gradient is rather small and negligible (Chapter II). It appears that the horizontal density gradients also play some role for the onset of transverse rolls.

The streamline pattern of the transverse-roll type disturbances in a longitudinal cross section is of particular interest and the secondary flow field configuration at the onset of instability is shown in Fig. 10 for the fully developed condition with $Pe = 1$, $Pr = 100$, $Ra^* = 1717.07$,

$a_1 = 3.117$. The stream function is defined by $u = -\psi/\delta z$ and $w = \psi/\delta x$. From the normal modes of disturbances, one has $w = w^+(z)e^{ia_1 x}$ and $\psi = \psi^+(\bar{z})e^{ia_1 x}$. Noting that $w^+ = w^*$, one obtains $\psi = (w^*/ja_1)e^{ia_1 x}$ where only the real part is considered to have physical meaning. The contour lines are based on $|v_{max}| = 1$ and the dimensionless wavelength $\lambda = 2\pi/a_1 = 2.0156$. The streamline pattern is quite similar to that of the longitudinal rolls and the eyes of the vortices are seen to be located at the center of the channel.

3.6 Concluding Remarks

1. The effects of axial heat conduction on the thermal instability of horizontal plane Poiseuille flow heated from below are studied for both longitudinal and transverse vortex disturbances. It is found that the transverse rolls with axes normal to the main flow are the preferred mode of disturbances for very low Peclet number regime (say $Pe < 1$) with $Pr > 1$ (or low Re) in the developing regions upstream and downstream of the thermal entrance. For other conditions, the longitudinal rolls with axes parallel to the basic velocity are the preferred mode of disturbances. The observed Peclet number effect on disturbance modes is consistent with experimental results for combined free and forced convection in porous media [19].

2. For given entrance temperature parameter θ_0 and Peclet number, the instability mechanism relating to the Prandtl number effect on the onset of longitudinal vortex

rolls in the thermal entrance region is clarified by studying the relative order of magnitude of the forcing terms involving axial and transverse basic temperature gradients in the energy disturbance equation (25).

3. For low Peclet number regime (say $Pe < 50$), the assumption of uniform entrance fluid temperature at the thermal entrance $\bar{x} = 0$ for basic temperature solution is not valid because of upstream heat penetration through $\bar{x} = 0$ into the upstream adiabatic region. At $Pe = 5$ and $\epsilon_0 = 1$, the predictions of critical Rayleigh number for longitudinal vortex rolls show considerable discrepancy between the two models with and without upstream heat penetration. The discrepancy increases with the decrease of Peclet number.

4. The present instability results can be used in predicting the onset of free convection effect on laminar heat transfer in horizontal wide rectangular channels [8]. For $Ra > Ra^*$, one has finite amplitude thermal convection problem and the classical Graetz formulation for thermal entrance region problem in a parallel-plate channel is not applicable. It should also be noted that the existence of stationary longitudinal vortex roll is confirmed in experiment [8]. However, the case of transverse vortex rolls remains to be confirmed by experiment.

5. The numerical experiments using 20 eigenvalues are also carried out to confirm the accuracy of the present numerical results. For $\bar{x} \geq 0.1$, the accuracy of Ra^* is

within one percent for $Pe = 1, 5, 10, 50$ and at $\bar{x} = 0^+$, the error of Ra^* is about one percent for $Pe = 1, 5$ and two percent for $Pe = 10$. The convergence of the numerical solution is thus confirmed.

6. Physically, as a low velocity main flow is imposed on Benard cells the "transverse-vortex disturbances" appear first. With further increase of steady main flow velocity, the "longitudinal vortex disturbances" appear. The effect of superposed steady flow on unstable fluid layers described in [5,20] is consistent with the present theoretical results.

7. The viscous dissipation effects are neglected within the scope of present work but should be studied in future. Apparently, the thermal radiation effect and other thermal boundary conditions such as convective boundary condition are also of practical interest.

CHAPTER IV

MAXIMUM DENSITY EFFECTS ON CONVECTIVE INSTABILITY OF HORIZONTAL PLANE POISEUILLE FLOWS IN THE THERMAL ENTRANCE REGION

A linear stability analysis is used to study the conditions marking the onset of secondary flow in the form of longitudinal vortices for plane Poiseuille flow of water in the thermal entrance region of a horizontal parallel-plate channel by a numerical method. The water temperature range under consideration is $0 \sim 30^\circ\text{C}$ and the maximum density effect at 4°C is of primary interest. The basic flow solution for temperature includes axial heat conduction effect and the entrance temperature is taken to be uniform at far upstream location $\bar{x} \rightarrow -\infty$ to allow for the upstream heat penetration through thermal entrance $\bar{x} = 0$. Numerical results for critical Rayleigh number are obtained for Peclet numbers 1, 10, 50 and thermal condition parameters (λ_1, λ_2) in the range of $-2.0 \leq \lambda_1 \leq -0.5$ and $-1.0 \leq \lambda_2 \leq 1.4$. The analysis is motivated by a desire to determine the free convection effect on freezing or thawing in channel flow of water.

Nomenclature

A	=	temperature difference ratio, $(T_1 - T_{\max})/\Delta T$
A_n, B_n, C_n, D_n	=	coefficients of infinite series defined by eqs. (5) and (6)
a	=	dimensionless wave number
D	=	operator, d/dz
f	=	$(1 - \lambda_1^2 + \lambda_2^2)$
Gr	=	Grashof number defined below eq. (14)
g	=	gravitational acceleration
L, l	=	height of channel and $L/2$
P, P_b	=	Liquid pressure ($P_b + P'$) and basic flow pressure
Pe	=	Peclet number, $4 U_m l / \alpha = Re Pr$
Pr	=	Prandtl number, ν / α
p	=	dimensionless perturbation pressure, $P' / (\rho \nu^2 / L^2)$
Ra	=	Rayleigh number, $Pr Gr$
Re	=	Reynolds number, $4 U_m l / \nu$
T, T_b, T_m, T_0	=	water temperature ($T_b + \theta'$), basic flow temperature, $(T_1 + T_2)/2$ and uniform upstream temperature.

- T_1, T_2, T_{max} = constant lower and upper plate temperatures, and maximum density temperature (4°C)
- U_b, U_m, u_b = axial and mean velocities and (U_b/U_m) of basic flow
- u, v, w = dimensionless perturbation velocity components, $(U', V', W')/(U/L)$
- $X, Y, Z,$ = Cartesian coordinates with origin at lower plate
- $x, y, z,$ = $(X, Y, Z)/L$
- x', z' = $(X'/(3/8)Pe, Z'/L)$
- \bar{x}, \bar{z} = transformed coordinates, $(x/(3Pe/16), z)$
- Y_n, R_n, F_n, Z_n = eigenfunctions
- Z' = transverse coordinate with origin at center of channel
- κ = thermal diffusivity
- $\lambda_n, \beta_n, \epsilon_n, \gamma_n$ = eigenvalues
- γ_1, γ_2 = temperature coefficients for density-temperature relationship
- θ = dimensionless temperature disturbance, $\theta'/\Delta T$
- θ_b, θ_0 = dimensionless temperature and uniform entrance temperature, $(T_b - T_m)/(T_2 - T_m)$ and $(T_0 - T_m)/(T_2 - T_m)$

- T_1, T_2 = thermal condition parameters defined below eq. (13)
- ν = kinematic viscosity
- ρ, ρ_{max} = density and maximum density at 4°C
- u, u_b = $(\phi_0 - 1)$, dimensionless basic velocity and temperature profiles, $(1/2)u_b = 3(z - z^2)/(1 - b)/2$
- ΔT = $(T_1 - T_2)$

Superscripts and Subscripts

- ' = perturbation quantity
- + = amplitude of disturbance quantity
- * = transformed perturbation variable or critical value
- b = basic flow quantity in unperturbed state
- 1,2 = upstream and downstream regions
- f = fully developed value

4.1 Introduction

Thermal instability analysis for horizontal liquid layers with a density maximum was made by Veronis [1], Deblee [2], Tien [3] using a parabolic temperature-density relationship valid for the temperature range 0-8°C and recently by Sun, Tien and Yen [4] using a third degree polynomial expansion for the temperature-density relationship applicable to the temperature 0 to 30°C. The onset of convection in a horizontal porous medium containing liquid with a density maximum was also studied by Sun, Tien and Yen [5]. It is noted that these thermal instability analyses are concerned with a horizontal liquid layer without main flow and represent an extension of the classical Benard problem to the case with maximum density effect.

The objective of this investigation is to study the effects of maximum density on the onset of longitudinal vortex rolls in the thermal entrance region of a horizontal plane Poiseuille flow where the lower and upper plate temperatures are maintained at T_1 and T_2 , respectively, with $T_1 > T_2$ or $T_1 < T_2$. Recent theoretical analysis [6] based on Boussinesq approximation and experimental investigation [7] show that the instability sets in as steady longitudinal vortices in the thermal entrance region of a horizontal parallel-plate channel heated from below when a critical temperature difference is exceeded. For basic flow in the low Peclet number regime, the upstream heat penetration through the thermal entrance $X = 0$ becomes significant and

The boundary condition of uniform entrance fluid temperature must be shifted from $X = 0$ to the far upstream location at $X = -\infty$ [8] to allow for the upstream heat conduction. The present work is motivated by the interest in determining the effect of free convection on ice formation or thawing in horizontal parallel-plate channels since water possesses maximum density at 4°C. The water temperatures under consideration range from 0 to 30°C and the temperature regime is also of interest in studying the decay and growth of ice in northern lakes or rivers.

4.2 Upstream and Downstream Temperature Solutions for Basic Flow

If one neglects the viscous dissipation effects, the energy equation and the boundary conditions in dimensionless form for the thermal entrance region problem (see Fig. 1) with axial heat conduction can be written as

$$\frac{2}{3} u_b \frac{\partial \theta_b}{\partial x'} = \frac{\partial^2 \theta_b}{\partial z'^2} + \left(\frac{8}{3Pe}\right)^2 \frac{\partial^2 \theta_b}{\partial x'^2} \quad (1)$$

$$\theta_b(-\infty, z') = 0, \quad \theta_b(x', 1)/\partial z' = \theta_b(x', -1)/\partial z' = 0$$

$$\text{for } -\infty < x' \leq 0 \quad (2)$$

$$\theta_b(0, z') = \theta_f, \quad \theta_b(x', 1) = 1, \quad \theta_b(x', -1) = -1 \quad \text{for } 0 \leq x' < \infty \quad (3)$$

$$\theta_{b1}(0, z') = \theta_{b2}(0, z'), \quad \partial \theta_{b1}(0, z') / \partial x' = \partial \theta_{b2}(0, z') / \partial x' \quad (4)$$

at $x' = 0$

where the dimensionless variables are defined in Nomenclature and $u_b = (3/2)(1 - z'^2)$ for a plane Poiseuille flow.

The solution methods described in [8,9] may be adapted to the present problem and the temperature solutions θ_{b1} and θ_{b2} in the adiabatic and heated regions, respectively, can be written as (Chapter II).

$$\theta_{b1}(x', z') = \theta_0 + \sum_{n=1}^{\infty} B_n Y_n(z') \exp(\alpha_n^2 x') + \sum_{n=1}^{\infty} A_n F_n(z') \exp(\epsilon_n^2 x'), \quad -\infty < x' \leq 0 \quad (5)$$

$$\theta_{b2}(x', z') = z' + \sum_{n=1}^{\infty} C_n R_n(z') \exp(-\beta_n^2 x') + \sum_{n=1}^{\infty} D_n Z_n(z') \exp(-\gamma_n^2 x'), \quad 0 \leq x' < \infty \quad (6)$$

where α_n , ϵ_n and Y_n , F_n are the even and odd eigenvalues and eigenfunctions, respectively, for the adiabatic (upstream) region. Similarly, β_n , γ_n and R_n , Z_n are the even and odd eigenvalues and eigenfunctions, respectively, for the heated (downstream) region. The details of the solution

method, the computed eigenvalues and the series expansion coefficients for the case $\theta_0 = 1$ are given in Chapter II. A fourth-order Runge-Kutta method [10], using two hundred equal steps is employed to obtain the eigenvalues and eigenfunctions from the numerical solution of the characteristic equations and the related boundary conditions. The series coefficients are calculated by using the matching conditions at $x = 0$ for both the temperature and temperature gradients after constructing orthonormal functions from the nonorthogonal eigenfunctions [8]. In this study, the infinite series are truncated at $n = 12$ and 8 for $Pe = 1$ and $Pe = 10, 50$, respectively. For the instability analysis, it is more convenient to shift the coordinate origin to the lower plate as shown in Fig. 1. As a result, the basic temperature profile now becomes $\phi_\theta = (1 - \theta_b)/2$.

4.3 Perturbation Equations

If the basic flow field is perturbed, one obtains $U = U_b + U'$, $V = V'$, $W = W'$, $T = T_b + \theta'$, $P = P_b + P'$ and $\rho = \rho_b + \delta\rho$. Introducing the dimensionless variables, $(\bar{x}, \bar{y}, \bar{z}) = (X, Y, Z)/L$, $(u, v, w) = (U', V', W')/(U/L)$, $p = P'/(\rho v^2/L^2)$, $\theta = \theta'/(\Delta T)$ and applying the linear stability analysis [5,6] using Boussinesq approximation, the perturbation equations in dimensionless form become

$$\frac{\partial u}{\partial x} + \frac{\partial v}{\partial y} + \frac{\partial w}{\partial z} = 0 \quad (7)$$

$$\text{Re} \left[\phi_u \frac{\partial u}{\partial x} + w \frac{d\phi_u}{dz} \right] = - \frac{\partial p}{\partial x} + \nabla^2 u \quad (8)$$

$$\text{Re} \phi_u \frac{\partial v}{\partial x} = - \frac{\partial p}{\partial y} + \nabla^2 v \quad (9)$$

$$\text{Re} \phi_u \frac{\partial w}{\partial x} = - \frac{\partial p}{\partial z} + \nabla^2 w - \frac{L^2}{2} \frac{\delta \rho}{\rho} g \quad (10)$$

$$\text{Re} \phi_u \frac{\partial \theta}{\partial x} + u \frac{\partial \phi_\theta}{\partial x} + w \frac{\partial \phi_\theta}{\partial z} = \frac{1}{\text{Pr}} \nabla^2 \theta \quad (11)$$

where $\phi_u = 3z(1-z)$, $\phi_\theta = (T_b - T_2)/\Delta T = (1 - \theta_b)/2$ and $\nabla^2 = \partial^2/\partial x^2 + \partial^2/\partial y^2 + \partial^2/\partial z^2$.

The density-temperature relationship for water in the temperature range 0 to 30°C is given as [5]

$$\rho = \rho_{\max} [1 - \gamma_1 (T - T_{\max})^2 - \gamma_2 (T - T_{\max})^3] \quad (12)$$

Here the temperature at maximum density T_{\max} is assumed to lie between the lower and upper plate temperatures T_1 and T_2 . Considering the change in the density, $\delta \rho = \rho(T_b + \theta') - \rho(T_b)$, caused by the temperature perturbation θ' , one obtains the following expression after neglecting the terms involving $(\theta')^2$ and $(\theta')^3$.

$$\delta \rho = -\rho_{\max} [2\gamma_1 (A\Delta T)\theta' (1 + (3\gamma_2/2\gamma_1)A\Delta T)] [1 - \lambda_1 \phi + \lambda_2 \phi^2] \quad (13)$$

where $\lambda_1 = (-1/A)[1 + (3\gamma_2/\gamma_1)(A\Delta T)]/[1 + (3\gamma_2/2\gamma_1)(A\Delta T)]$,
 $\lambda_2 = (1/A^2)[(3\gamma_2/2\gamma_1)A\Delta T]/[1 + (3\gamma_2/2\gamma_1)(A\Delta T)]$, $\phi_0 =$
 $(T_b - T_2)/\Delta T$, $\phi = \phi_0 - 1$, $\Delta T = T_1 - T_2$ and $A = (T_1 - T_{\max})/\Delta T$.

The thermal parameters λ_1 and λ_2 were first introduced by Sun, Tien and Yen [4,5].

The dependent variables u , v and p can be eliminated from the three momentum equations by using continuity equation. Noting that $\rho = \rho_{\max}$ from Boussinesq approximation, one then obtains

$$\text{Re}\phi_u \frac{\partial^2 w}{\partial x^2} - \text{Re} \frac{d^2 \phi_u}{dz^2} \frac{\partial w}{\partial x} = \nu^2 v^2 w$$

$$+ \text{Gr}\nu_1^2 [(1 - \lambda_1\phi + \lambda_2\phi^2)\theta] \quad (14)$$

where $\text{Gr} = g(2\gamma_1 A\Delta T)(\Delta T)L^3 [1 + (3\gamma_2/2\gamma_1)(A\Delta T)]/\nu^2$ and
 $\nu_1^2 = \nu^2/\partial x^2 + \nu^2/\partial y^2$. Since the disturbance variable u appears also in energy equation (11), equations (8), (14) and (11) now become the set of governing perturbation equations. It is seen that because of the presence of $(\Delta T)^2$ in the expression for Gr , the onset of secondary flow is possible for heating from below as well as above.

At the onset of instability in the form of steady longitudinal vortices (the type of Taylor-Görtler vortices), one may assume the perturbation form of $f = f^+(z)e^{iay}$ for the disturbance quantities w , u and θ [6]. Furthermore,

for vortex-type instability $\partial p / \partial x = 0$ and the set of perturbation equations becomes:

$$(D^2 - a^2)^2 w^+ = Gr[a^2 f - \frac{\partial^2 f}{\partial x^2}] \theta^+ \quad (15)$$

$$(D^2 - a^2) u^+ = Re w^+ \frac{d\phi_u}{dz} \quad (16)$$

$$(D^2 - a^2) \theta^+ = Pr[u^+ \frac{\partial \phi_\theta}{\partial x} + w^+ \frac{\partial \phi_\theta}{\partial z}] \quad (17)$$

where $f = 1 - \lambda_1 \phi + \lambda_2 \phi^2$ and $D = d/dz$.

In order to use the parameters Pr , Pe and Ra instead of Pr , Re and Gr which appear in the above set of equations, one may further introduce the transformations, $x' = (3Pe/16)\bar{x}$, $z = \bar{z}$, $u^+ = Re u^*$, $w^+ = w^*$, and $\theta^+ = Pr \theta^*$. One thus obtains

$$(D^2 - a^2)^2 w^* = Ra[a^2(1 - \lambda_1 \phi + \lambda_2 \phi^2) + \{(-\lambda_1 + 2\lambda_2 \phi) \frac{\partial^2 \phi}{\partial x^2} + 2\lambda_2 (\frac{\partial \phi}{\partial x})^2\} (\frac{16}{3Pe})^2] \theta^* \quad (18)$$

$$(D^2 - a^2) u^* = w^* \frac{d\phi_u}{d\bar{z}} \quad (19)$$

$$(D^2 - a^2) \theta^* = (\frac{16}{3Pr}) u^* \frac{\partial \phi_\theta}{\partial \bar{x}} + w^* \frac{\partial \phi_\theta}{\partial \bar{z}} \quad (20)$$

The boundary conditions for the disturbances at the walls are

$$w^* = Dw^* = u^* = \theta^* = 0 \text{ at } \bar{z} = 0 \text{ and } 1$$

For given values of θ_0 , Pr , Pe and \bar{x} , one is interested in determining the minimum critical Rayleigh number and the corresponding wave number through the solution of the coupled equations (18) to (21). The numerical method of solution [6] employing the higher order finite-difference scheme developed by Thomas [11] may be applied to the present eigenvalue problem. The details are given in Chapter III.

4.4 Numerical Results and Discussion

The Prandtl number of water varies from 13.6 at 0°C to 7.02 at 20°C and is taken to be 10 in this study. The temperature coefficients for water [12] are $\gamma_1 = 7.7319 \times 10^{-6} (\frac{1}{^\circ\text{C}})^2$ and $\gamma_2 = -5.1821 \times 10^{-8} (\frac{1}{^\circ\text{C}})^3$ with a standard deviation of 0.4×10^{-5} . The details of the determination of the coefficients γ_1 and γ_2 using the method of regression are given in Appendix III. One notes that the parameter $A = (T_1 - T_{\max})/\Delta T$ is always positive and λ_1 is always negative for the temperature range $0-30^\circ\text{C}$ under consideration. The expression for λ_2 reveals that the value λ_2 is negative when $T_1 > T_{\max}$ (heating from below) and positive when $0^\circ\text{C} \leq T_1 < T_{\max}$ (heating from above). For $T_1 > 4^\circ\text{C}$, the potentially unstable layer is confined to the region $T_1 > T > 4^\circ\text{C}$ near

the lower plate. Similarly, when $0 \leq T_1 < 4^\circ\text{C}$ the potentially unstable layer with temperature ranging from T_1 to 4°C is also located near the lower plate. It is noted that without maximum density effects, the case of heating from above is always stable. As $T_2 \rightarrow T_{\text{max}}$, $A \rightarrow 1$ and the whole channel becomes potentially unstable whether $T_1 \leq 4^\circ\text{C}$ or $T_1 \geq 4^\circ\text{C}$. This is in contrast to the classical Benard problem where the horizontal fluid layer is unstable only when heating is from below. Also as $T_1 \rightarrow T_{\text{max}}$, $A \rightarrow 0$ and the whole layer becomes potentially stable.

The typical numerical results for critical Rayleigh number and wave number are listed in Tables 1 to 5 for $Pe = 1, 10, 50$ and the ranges of parameters $-2.0 \leq \lambda_1 \leq -0.5$, $-1.0 \leq \lambda_2 \leq 1.4$. The special case of $\lambda_2 = 0$ corresponds to the parabolic density-temperature relationship ($\lambda_2 = 0$) for the temperature range $0-8^\circ\text{C}$ and the parameter λ_1 becomes simply $\lambda_1 = (-1/A)$. The effect of Peclet number on the axial distribution of the critical Rayleigh number is shown in Fig. 2 for $\lambda_1 = -0.5$ (or $A = 2$) and $\lambda_2 = 0$ (or $\gamma_2 = 0$). The axial heat conduction is clearly seen to have a destabilizing effect near the thermal entrance ($\bar{x} = 0$) and the trend reverses before approaching the asymptotic value of $Ra^* = 2275$ corresponding to a linear basic temperature profile. The upstream temperature profile ϕ_θ , becomes practically uniform at $\bar{x} = -2, -1$ and -0.05 for $Pe = 1, 10$ and 50 , respectively (Chapter II), and it is concluded that $Ra^* \rightarrow \infty$ there.

The instability results for $Pe = 1$ and $\lambda_1 = -0.5, -1$ are presented graphically in Fig. 3 for various values of λ_2 . Since the upstream temperature profile is uniform at $\bar{x} = -2$, the asymptotic value for Ra^* in the upstream region is infinity. The downstream asymptotic results agree exactly with those reported in [4] and the parametric effect of λ_2 is also similar to that of Fig. 4 in [4]. The two special cases of $T_2 = 0^\circ C$ and $T_1 = 0^\circ C$ [4] are of considerable practical interest since they correspond to the cases of melting from below (heating from below) and melting from above (heating from above), respectively. The physical interpretation of the numerical results can best be provided by considering a specific example. From Table 5 of [4] for the case of melting from below ($T_2 = 0$) for a horizontal liquid layer, one finds that at $\lambda_1 = -1.014$ and $\lambda_2 = -0.301$ ($T_1 = 18^\circ C$), the theoretical and experimental values of Ra^* are 4,021 and 4,663, respectively. The thermal instability of a horizontal liquid layer considered in [4] corresponds to the fully developed case with a linear basic temperature profile (independent of Peclet number) in the present problem. A simple linear interpolation of the asymptotic results for $\lambda_2 = 0$ and -0.5 with $\lambda_1 = -1.0$ in Table 3 gives $Ra^* = 4,100$ for $\lambda_1 = -1.0$ and $\lambda_2 = -0.3$. Fig. 3 also shows that the present result agrees with $Ra^* = 4,021$ for $\lambda_1 = -1.014$ and $\lambda_2 = -0.301$ given in [4]. Noting the parametric effect of λ_1 for a given value of λ_2 shown in Fig. 3, one sees that the trend of the present

asymptotic results also agrees with the experimental and theoretical results given in Table 4 of [4] for the case of melting from above ($T_1 = 0$, heating from above). The above qualitative comparison suggests that the present instability analysis may be used in predicting the onset of longitudinal vortex rolls in a horizontal parallel-plate channel with main flow involving melting from below or above. This information is of particular interest in assessing the free convection effect on ice formation or thawing in horizontal channels.

Further instability results for $Pe = 1$ and $\lambda_2 = 1.4$ are shown in Fig. 4 with λ_1 as parameter. As noted earlier, positive λ_2 signifies heating from above with $0^\circ C \leq T_1 < 4^\circ C$. The vertical distributions of the disturbances u^* , w^* and θ^* together with the basic profiles ϕ_u and ϕ_θ are illustrated in Fig. 5 and 6 for $Pe = 1$, $\lambda_1 = -0.5$ and $\lambda_2 = -1.0$ at various axial positions. In the plotting, the maximum amplitude of each disturbance is taken to be 0.1.

The profiles for u^* and θ^* at $\bar{x} = 5$ are further illustrated in Fig. 7 for $Pe = 1$, $\lambda_1 = -0.5$ and $\lambda_2 = 0.8, -1.0$. It is seen that u^* is negative near the lower plate and positive near the upper plate. The relatively weaker disturbance u^* near the upper plate for $\lambda_2 = -1.0$ as compared with u^* for $\lambda_2 = 0.8$ is apparently related to the smaller unstable layer thickness near the lower plate which is indicated by the higher critical Rayleigh number. In contrast to the reversal of sign for u^* , the profile θ^* for

$\lambda_2 = -1.0$ is quite similar to that of $\lambda_2 = 0.8$ except that the position of maximum θ^* is located nearer to the lower plate. The information on the location of maximum θ^* is useful in the experimental determination of critical Rayleigh number by measurement of spanwise temperature distribution [7].

4.5 Concluding Remarks

1. The accuracy and convergence of the numerical solution are checked by an excellent agreement between the present downstream asymptotic results and the theoretical results for liquid layer reported in [4]. The latter theoretical results in turn are confirmed by the experimental investigation as indicated by the comparison shown in Fig. 7 of [4]. The matching of the critical Rayleigh numbers for the upstream and downstream regions at $\bar{x} = 0$ also provides a severe test for the convergence of the numerical solution and the critical Rayleigh numbers for the upstream and downstream regions are found to agree within three significant digits at $\bar{x} = 0$. The numerical results can be seen in Tables 1 to 5. Furthermore, it is found that the increase of the number of eigenvalues and series coefficients to 20 for the basic temperature solution improves only slightly the degree of the matching at $\bar{x} = 0$.
2. The results of the present thermal instability analysis show that the effect of axial heat conduction on the onset of longitudinal vortex rolls in horizontal plane

Poiseuille flow is important when $Re < 5$ or $Pe < 50$. For water with $T_1 < T_{max} < T_2$, the density inversion effect must be considered in thermal instability analysis [4]. The present analysis may be used in assessing the importance of free convection effect on melting and ice formation problems in horizontal parallel-plate channels by considering the case with $T_1 = 0^\circ C$ or $T_2 = 0^\circ C$. The free convection effect involving the density inversion is also of interest in studying the melting of ice formation problems for northern lakes or rivers.

3. Since the entrance temperature parameter θ_0 , two thermal condition parameters (λ_1, λ_2) and Peclet number are involved, only sample numerical results with $\theta_0 = 1$, are presented. The numerical method is confirmed to be applicable to the ranges of parameters, $-2.0 \leq \lambda_1 \leq -0.5$ and $-1.0 \leq \lambda_2 \leq 1.4$. Outside these ranges, the unstable layer with temperature distribution in the range $T_1 < T < T_{max}$ near the lower plate becomes so thin that the buoyancy effect tends to be washed out by the forced main flow. In other words, as A decreases or the relative magnitude of $(T_1 - T_{max})$ decreases with respect to $\Delta T = T_1 - T_2$, then correspondingly the unstable layer thickness also decreases. It is also noteworthy that the parametric ranges for λ_1 and λ_2 in this study are narrower than those indicated in [4].

4. When one assumes the entrance temperature at $\bar{x} = 0$ to be uniform as in the case of classical Graetz problem [6], then the thermal boundary layer develops starting

at $\bar{x} = 0$. For the basic flow solution for temperature considered in this study, the fluid temperature is taken to be uniform at $\bar{x} = -\infty$ in order to accommodate the effect of upstream conduction and consequently the thermal boundary layer thickness is not zero at $\bar{x} = 0$. As a matter of fact, the basic temperature profiles at $\bar{x} = 0$ for $Pe = 1$ and 10 [10,11] show that the heat already penetrates to the upper plate and the whole cross section is potentially unstable (see Fig. 1). It is then seen that for $Pe = 1$ and 10, the concept of thermal boundary layer is no longer applicable. The foregoing fact accounts for the decrease of critical Rayleigh number near $\bar{x} = 0$ with the decrease of Peclet number as shown in Fig. 2. When $Pe > 100$ or $Pe \rightarrow \infty$, the critical Ra^* becomes infinity at $\bar{x} = 0$.

5. The experimental instability data in the thermally developing region of a horizontal channel flow of water in the temperature range $0 \sim 30^\circ\text{C}$ do not appear to be available in the literature. In view of the importance of environmental heat transfer problem (freezing or thawing) involving 4°C for water, the experimental investigation is apparently in order.

6. The potentially unstable layer with temperature ranging from T_1 to T_{\max} near the lower plate may be seen more clearly by considering the fully developed region where the basic temperature profile is linear. The upper limit of the unstable layer is then given by $z = 1 - (T_{\max} - T_2)/(T_1 - T_2)$. By keeping T_2 constant, one finds

that $(\partial z / \partial T_1)_{T_2} = 0$ for the case $T_{\max} = T_2$ (heating from below). This means that as T_1 increases the unstable layer thickness also increases. On the other hand, by keeping T_1 constant one obtains $(\partial z / \partial T_2)_{T_1} < 0$ indicating that as T_2 increases the unstable layer z decreases when $T_1 = T_{\max}$ (heating from above). Physically, positive or negative value of λ_2 signifies heating either from above or below whereas the larger value of $|\lambda_1|$ indicates the smaller unstable layer with the corresponding higher critical Rayleigh number. The above observation is useful in physical interpretation of λ_1 and λ_2 and agrees with the results shown in Tables 3, 4 and 5 of [4].

CHAPTER V

VISCOUS DISSIPATION EFFECTS ON CONVECTIVE INSTABILITY AND HEAT TRANSFER IN PLANE POISEUILLE FLOW HEATED FROM BELOW

The effects of viscous dissipation on the onset of instability for longitudinal vortices in the thermal entrance region of a horizontal parallel-plate channel are studied by a numerical method for the case when the lower plate is heated isothermally and the upper one is cooled isothermally. Numerical results are obtained for $Pr = 0.1, 0.7, 10$ and 100 . It is found that viscous heating has a destabilizing influence. The effect is significant for large Prandtl number fluid ($Pr \geq 10$) but is insignificant for small Prandtl number fluid ($Pr \leq 0.7$). The viscous dissipation effects on thermal entrance region heat transfer for basic flow (without secondary flow) are also studied.

Nomenclature

- a = dimensionless wave number
 Br = Brinkman number, $\mu U_m^2 / (k \theta_c)$
 C_n, D_n = coefficients in the series expansion of θ_e
 C'_n, K_n = coefficients defined by eq. (10)
 c_p = specific heat at constant pressure
 D = d/dz
 Gr = Grashof number, $g\beta(\Delta T)L^3/\nu^2$
 g = gravitational acceleration
 h_1, h_2 = local heat transfer coefficients at lower and upper plates
 k = thermal conductivity
 L = a distance between two horizontal flat plates and $L/2$
 Nu_1, Nu_2 = local Nusselt numbers, $h_1(4\ell)/k, h_2(4\ell)/k$
 P, P_b = fluid pressure ($P_b + P'$) and pressure for basic flow
 Pe = Peclet number, $4 U_m \ell / \alpha = RePr$
 Pr = Prandtl number, ν/α
 p = dimensionless perturbation pressure, $P' / (\rho \nu^2 / L^2)$

- q_1, q_2 = rate of heat transfer per unit area,
 $-k(\partial T/\partial Z')_{Z=-l}, -k(\partial T/\partial Z')_{Z=l}$
- Ra = Rayleigh number, $g\beta\Delta TL^3/\nu\alpha = PrGr$
- Re = Reynolds number, $4U_m l/\nu$
- R_n, S_n = even and odd eigenfunctions
- T, T_b, T_{bm}, T_0 = fluid temperature ($T_b + \theta'$), fluid
 temperature of basic flow, bulk tempera-
 ture, and uniform entrance temperature
- T_1, T_2, T_m = constant lower and upper plate tempera-
 tures, and $(T_1 + T_2)/2$
- U_b, U_m, u_b = axial and mean velocities and (U_n/U_m)
 of basic flow
- u, v, w = dimensionless perturbation veloci-
 ty components, $(U', V', W')/(\nu/L)$
- X, Y, Z = Cartesian coordinates with origin at
 lower plate
- x = $x'/(3/16)Pe = \bar{x}$
- x', y', z = dimensionless coordinates, $(X, Y, Z)/L$
- \bar{x}, \bar{z} = dimensionless coordinates with origin at
 center of channel, $(X/(3/8)Pe, Z'/l =$
 $2z - 1)$
- Z' = transverse coordinate with origin at
 center of channel
- α = thermal diffusivity

- α = coefficient of thermal expansion
- γ_n = even and odd eigenvalues
- $\theta, \theta', \theta_0$ = dimensionless perturbation, basic flow and entrance temperatures, $\theta'/\Delta T$, $(T_b - T_m)/(T_2 - T_m)$, $(T_0 - T_m)/(T_2 - T_m)$
- c, e, f = characteristic temperature difference $(T_2 - T_m) = (T_2 - T_1)/2$, and dimensionless fluid temperatures defined by eq. (3)
- θ', θ_{bm} = perturbation and dimensionless bulk temperatures
- ν = fluid viscosity
- ν_c = kinematic viscosity
- ρ = fluid density
- u, θ = dimensionless basic velocity and temperature profiles $(1/2)u_b = 3(z - z^2)$, $(1 - \theta_b)/2$
- ΔT = $(T_1 - T_2) = -2\theta_c$

Superscripts and Subscripts

- $\hat{}$ = perturbation quantity
- $+$ = amplitude of disturbance quantity
- $*$ = transformed perturbation variable or critical value
- b = basic flow quantity in unperturbed state
- f = fully developed value

- γ_n = coefficient of thermal expansion
- γ_n = even and odd eigenvalues
- $\theta, \theta_b, \theta_0$ = dimensionless perturbation, basic flow and entrance temperatures, $\theta'/\Delta T$, $(T_b - T_m)/(T_2 - T_m)$, $(T_0 - T_m)/(T_2 - T_m)$
- $\theta_c, \theta_e, \theta_f$ = characteristic temperature difference $(T_2 - T_m) = (T_2 - T_1)/2$, and dimensionless fluid temperatures defined by eq. (3)
- θ', θ_{bm} = perturbation and dimensionless bulk temperatures
- μ = fluid viscosity
- ν = kinematic viscosity
- ρ = fluid density
- u, u_e = dimensionless basic velocity and temperature profiles $(1/2)u_b = 3(z - z^2)$, $(1 - \theta_b)/2$
- ΔT_c = $(T_1 - T_2) = -2\theta_c$

Superscripts and Subscripts

- ' = perturbation quantity
- + = amplitude of disturbance quantity
- * = transformed perturbation variable or critical value
- b = basic flow quantity in unperturbed state
- f = fully developed value

5.1 Introduction

Thermal instability of a plane Poiseuille flow in the thermal entrance region of a horizontal parallel-plate channel heated from below has been studied theoretically by Hwang and Cheng [1] and experimentally by Kamotani and Ostrach [2]. For Graetz problem (thermal entrance region problem) in pipes or channels, the effect of viscous dissipation on convective heat transfer is represented by the frictional heating parameter, Eckert or Brinkman number. When the value of the parameter is not small (say $Br > 0.01$), it is expected that the viscous dissipation will have an effect on the onset of longitudinal vortex rolls in the parallel-plate channel and on heat transfer in the subsequent post-critical regime.

Thermal instability in a horizontal fluid layer with a non-linear basic temperature profile caused by a uniform internal heat generation was studied by Sparrow, Goldstein and Jonsson [3]. It is noted that the role of the viscous dissipation term in the energy equation is qualitatively similar to that of internal heat generation term. The influence of viscous dissipation on Benard finite amplitude convection was studied by Turcotte et al. [4]. The viscous dissipation effect on Benard problem arises only if the main flow exists and apparently the problem has not been considered in the past.

The purpose of this investigation is to study the role of the viscous dissipation in thermal instability of the

plane Poiseuille flow between two horizontal flat plates where the lower plate is maintained at higher temperature T_1 and the upper plate T_2 with uniform entrance temperature $T_0 = T_2$. It is known that the instability sets in as steady longitudinal vortices in the thermal entrance region when a critical temperature difference is exceeded [1,2]. Since the basic temperature profile is required in the present thermal instability analysis, the Graetz problem with viscous dissipation effects will be considered first and the heat transfer results will also be presented.

5.2 Graetz Problem with Viscous Dissipation Effects and Basic Solution

For Graetz problem (as shown in Fig. 1) with viscous heating, the energy equation and the associated boundary conditions in dimensionless form can be written as

$$\frac{2}{3} u_b \frac{\partial \theta_b}{\partial \bar{x}} = \frac{\partial^2 \theta_b}{\partial \bar{z}^2} + Br \left(\frac{du_b}{d\bar{z}} \right)^2 \quad (1)$$

$$\theta_b(0, \bar{z}) = \theta_0, \theta_b(\bar{x}, 1) = 1, \theta_b(\bar{x}, -1) = -1. \quad (2)$$

where the dimensionless variables and parameters are defined in the Nomenclature and $u_b = (3/2)(1 - \bar{z}^2)$ for plane Poiseuille

Taking cognizance of the fully developed condition,

the solution of eq. (1) can be written in the following form:

$$\theta_b = \theta_f(\bar{z}) + \theta_e(\bar{x}, \bar{z}) \quad (3)$$

where θ_f (fully developed solution) and θ_e (difference temperature) satisfy the following two sets of equations:

$$\frac{d^2 \theta_f}{d\bar{z}^2} + 9 \text{Br} \bar{z}^2 = 0, \quad \theta_f(1) = 1, \quad \theta_f(-1) = -1 \quad (4)$$

$$(1 - \bar{z}^2) \frac{\partial^2 \theta_e}{\partial \bar{x}^2} = \frac{\partial^2 \theta_e}{\partial \bar{z}^2}, \quad \theta_e(0, \bar{z}) = \theta_0$$

$$\theta_e(\bar{x}, 1) = \theta_e(\bar{x}, -1) = 0 \quad (5)$$

The solution for θ_f is

$$\theta_f = \bar{z} + \frac{3}{4} \text{Br}(1 - \bar{z}^4) = \bar{z} + \text{Br}f(\bar{z}) \quad (6)$$

where $f(\bar{z}) = (3/4)(1 - \bar{z}^4)$. The general solution of eq. (5) can be constructed in the form of infinite series [5] as

$$\theta_e = \sum_{n=1}^{\infty} C_n R_n(\bar{z}) \exp(-\beta_n^2 \bar{x}) + \sum_{n=1}^{\infty} D_n S_n(\bar{z}) \exp(-\gamma_n^2 \bar{x}) \quad (7)$$

where β_n , γ_n and R_n , S_n are the even and odd eigenvalues and eigenfunction, respectively, of the following Sturm-Liouville problems.

$$\frac{d^2 R_n}{d\bar{z}^2} + \beta_n^2 (1 - \bar{z}^2) R_n = 0, \quad R_n(\pm 1) = 0 \quad (8)$$

$$\frac{d^2 S_n}{d\bar{z}^2} + \gamma_n^2 (1 - \bar{z}^2) S_n = 0, \quad S_n(\pm 1) = 0 \quad (9)$$

The eigenvalues and eigenfunctions are obtained by applying the fourth-order Runge-Kutta method [6] employing two hundred equal steps. Applying the boundary condition at the channel entrance $\bar{x} = 0$ and using the orthogonality property of the Sturm-Liouville system, one obtains the following expressions for C_n and D_n .

$$C_n = C_n' + BrK_n \quad (10)$$

$$\text{where } C_n' = \left[\int_0^1 (1 - \bar{z}^2) R_n(\bar{z}) d\bar{z} \right] / \left[\int_0^1 (1 - \bar{z}^2) R_n^2(\bar{z}) d\bar{z} \right]$$

$$\text{and } K_n = - \left[\int_0^1 f(\bar{z}) (1 - \bar{z}^2) R_n(\bar{z}) d\bar{z} \right] / \left[\int_0^1 (1 - \bar{z}^2) R_n^2(\bar{z}) d\bar{z} \right]$$

$$D_n = - \left[\int_0^1 \bar{z} (1 - \bar{z}^2) S_n(\bar{z}) d\bar{z} \right] / \left[\int_0^1 (1 - \bar{z}^2) S_n^2(\bar{z}) d\bar{z} \right] \quad (11)$$

Here Simpson's rule (IBM-SSP) is used for numerical integration. It is noted that when $\theta_0 = 1$, the first coefficient C'_n is identical to that of the Graetz problem and the second coefficient K_n corresponds to the viscous dissipation effect. The first eight values for C'_n , K_n , D_n as well as β_n , γ_n are listed in Table 1.

Although the basic solution to be used for the thermal instability problem is of primary interest here, the local Nusselt numbers Nu_1 and Nu_2 at the lower and upper plates defined by the following equations for the case of heating from below ($T_1 > T_2$) are also of practical interest.

$$Nu_1 = \frac{h_1(4\ell)}{k} = \frac{(4\ell)}{k} \frac{q_1}{(T_1 - T_{bm})} = \frac{4}{1 + \theta_{bm}} \left(\frac{\partial \theta_b}{\partial \bar{z}} \right)_{\bar{z}=-1} \quad (12)$$

$$Nu_2 = \frac{h_2(4\ell)}{k} = \frac{(4\ell)}{k} \frac{q_2}{(T_{bm} - T_2)} = \frac{4}{1 - \theta_{bm}} \left(\frac{\partial \theta_b}{\partial \bar{z}} \right)_{\bar{z}=1} \quad (13)$$

where the bulk temperature θ_{bm} is

$$\begin{aligned} \theta_{bm} &= (T_{bm} - T_m)/(T_2 - T_m) = \int_{-1}^1 \theta_b u_b d\bar{z} / \int_{-1}^1 u_b d\bar{z} \\ &= (24/35)Br + (3/2) \sum_{n=1}^{\infty} C'_n \exp(-\beta_n^2 \bar{x}) \int_0^1 (1-\bar{z}^2) R_n(\bar{z}) d\bar{z} \quad (14) \end{aligned}$$

Of particular practical interest here are the following

asymptotic results ($\bar{x} \rightarrow \infty$) valid far downstream from the thermal entrance. $Nu_{1f} = 4(1 + 3Br)/(1 + 24Br/35)$,
 $Nu_{2f} = 4(1 - 3Br)/(1 - 24Br/35)$.

$$\bar{z}_f = \bar{z} + (3/4)Br (1 - \bar{z}^{-4}), \quad \bar{z}_{df} = (24/35)Br \quad (15)$$

5.3 Perturbation Equations for Thermal Instability Problem

Within the thermal boundary layer, a top-heavy situation prevails and the layer occupying only partial region of the channel is potentially unstable. It is readily seen that the thermal boundary layer is more stable than the fully-developed region where the whole region is subjected to an adverse temperature gradient. At this point, it is convenient to shift the coordinate origin to the lower plate as shown in Fig. 1 for thermal instability problem. Applying the method of small disturbances (a linearization about the basic flow) and using the Boussinesq approximation, the perturbation equations in dimensionless form can be written as [1]:

$$Re \left(u \frac{\partial}{\partial x'} + v^2 w - \frac{d^2 u}{dz^2} \frac{\partial w}{\partial x'} \right) = v^2 v^2 w + Gr \frac{\partial^2 \theta}{\partial z^2} \quad (16)$$

$$Re \left(u \frac{\partial u}{\partial x'} + w \frac{d u}{dz} \right) = - \frac{\partial p}{\partial x'} + v^2 u \quad (17)$$

$$Re \left(u \frac{\partial \theta}{\partial x'} + u \frac{\partial \theta}{\partial x'} + w \frac{\partial \theta}{\partial z} \right) = \frac{1}{Pr} v^2 \theta - \frac{4Br}{Pe} \frac{d u}{dz} \left(\frac{\partial u}{\partial z} + \frac{\partial w}{\partial x'} \right) \quad (18)$$

where the dimensionless quantities and parameters are defined in Nomenclature, $\phi_u = (1/2)u_b = 3(z - z^2)$, $\phi_\theta = (1 - \phi_b)/2$, $\nabla_1^2 = \partial^2/\partial x'^2 + \partial^2/\partial y'^2$, and $\nabla^2 = \partial^2/\partial x'^2 + \partial^2/\partial y'^2 + \partial^2/\partial z'^2$.

It is noted that the terms involving Br on the right-hand side of perturbation eq. (18) represent the viscous dissipation effect.

At the state of neutral stability, one may assume that the perturbations θ , w , and u have the form, $f = f^+(z)e^{i\alpha j}$, for instability in the form of longitudinal vortices (the type of Taylor-Görtler vortices) [1]. The set of perturbation equations then becomes:

$$(D^2 - a^2)^2 w^+ = a^2 Gr \theta^+ \quad (19)$$

$$(D^2 - a^2)u^+ = Re \frac{d\phi_u}{dz} w^+ \quad (20)$$

$$(D^2 - a^2)\theta^+ = Pr(u^+ \frac{\partial \phi_\theta}{\partial x'} + w^+ \frac{\partial \phi_\theta}{\partial z}) + \frac{4Br}{Re} \frac{d\phi_u}{dz} Du^+ \quad (21)$$

where $D = d/dz$. In view of the dimensionless basic flow variables, it is convenient to introduce the transformations, $w^+ = w^*$, $\theta^+ = Pr\theta^*$, $u^+ = Reu^*$, $x' = (3/16)Pex$ and one finally obtains,

$$(D^2 - a^2)^2 w^* = a^2 Ra \theta^*$$

$$(D^2 - a^2)u^* - \frac{d}{dz}u^* w^* \quad (23)$$

$$(D^2 - a^2)u^* - \frac{3}{16Pr} \frac{d^2 u^*}{dx^2} + \frac{d}{dz}u^* w^* + \frac{4Br}{Pr} \frac{d}{dz}u^* Du^* \quad (24)$$

$$w^* - Dw^* - u^* = v^* = 0 \quad \text{at } z = 0 \text{ and } 1 \quad (25)$$

For given values of Br and Pr, one is interested in determining the critical Rayleigh number and the corresponding wave number for the onset of instability through the solution of the set of eq. (22) to (25). The method of solution for the eigenvalue problem used in [1] may be applied to the present problem and the details of the numerical solution will be omitted.

5.4 Results and Discussion

5.4.1 Heat Transfer Results for Graetz Problem

The numerical results are obtained for $\theta_0 = 1$ corresponding to the case with the entrance temperature T_0 being equal to the upper plate temperature T_2 . The developing temperature profiles are shown in Fig. 1 and 2 for Br = 0 and -2.5, respectively. The Brinkman number effect on temperature profiles at $x = 0.06, 0.2$ and 2 is shown in Fig. 3 to 5 where the local bulging of the profile near the upper and lower plates is apparently caused by viscous heating. At $x = 2$, the temperature profiles become fully esta-

blished. In interpreting the result, it is well to note that in practice the Eckert number ($Ec = Br/Pr$) can be of order one. Consequently, $Br \approx 100$, for example, is practicable only if Prandtl number is of order 10^2 . An inspection of the developing temperature profiles readily identifies the region of the channel cross-section where the top-heavy situation exists. The axial distributions of the bulk mean temperature θ_{bm} and the local Nusselt numbers Nu_1 , Nu_2 are shown in Fig. 6 and 7, respectively. Fig. 6 shows that as the magnitude of Br increases, the value of Nu_1 decreases and that of Nu_2 increases. The change of sign for Nu_1 is related to the reversal of heat transfer direction. Equation (12) shows that as $\theta_{bm} \rightarrow -1$, $Nu_1 \rightarrow \infty$ depending on the sign of $(\partial\theta/\partial z)_{z=-1}$. Apparently, the singularity for Nu_1 has no particular physical significance. In Fig. 7, the effects of Brinkman number on the asymptotic results are of special interest.

6.4.2 Instability Results

The influence of viscous dissipation on the onset of longitudinal vortices in the thermal entrance region of plane Poiseuille flow between two horizontal plates with heating from below is of principal interest in this study. The instability results are shown in Fig. 8 and 9 for $Pr = 0.1, 0.7, 10$ and 10^2 , respectively. As noted in [1], with $Pr = 0.1$ the flow is more unstable in the thermal entrance region than in the fully-developed region. The

viscous heating is clearly seen to be a destabilizing effect but it depends also on Prandtl number. With $Pr = 0.1$, $Br = -0.1$ and $Pr = 0.7$, $Br = -1$, the viscous heating effect on critical Rayleigh numbers in the thermal boundary layer appears to be negligible practically. For $Pr = 10$ and 10^4 , a local maximum for Ra^* appears at $x = 0.4$ before approaching the asymptotic value when the magnitude of Br exceeds a certain value. Since this phenomenon does not occur for the case without viscous dissipation effects [1], one may attribute the cause to the combined effect of the forcing terms on the right-hand side of the disturbance eq. (24). In this connection, one should note that the developing basic temperature profiles depend on Br only. The reason for the local stabilization near $x = 0.4$ is not immediately clear and remains to be clarified.

At $Br = -1$, the effect of Prandtl number on Ra^* in the entry region is shown in Fig. 10 where the critical Rayleigh number is seen to be a monotonically decreasing function of x . One also observes that Prandtl number has a stabilizing effect but the effect diminishes as fully-developed condition is approached. It is found that for fully-developed flow the ratio of the term $(\partial^2/\partial z^2)w^*$ over the term $4(d_u/\partial z)Du^*$ on the right-hand side of eq. (24) is of order 10^{-1} for $Br = -1$. Thus, the critical Rayleigh numbers for $Pr = 0.7$ and 100 differ very little at $Br = -1$ as x

For thermally fully-developed Poiseuille flow, a

qualitative comparison between the present thermal instability problem and that of a horizontal fluid layer with uniform heat sources [3] is possible. For fully developed flow we obtain $\partial\phi_0/\partial x = 0$. Furthermore, without viscous dissipation ($Br = 0$) the perturbation eq. (23) is not required and the resulting set of equations becomes:

$$(D^2 - a^2)^2 w^* = a^2 Ra \theta^*, \quad (D^2 - a^2)\theta^* = (\partial\phi_0/\partial z)w^* \quad (26)$$

The above set of perturbation equations is apparently equivalent to that of [3] or the classical Benard problem and the critical Rayleigh number is known to be 1708. For a horizontal fluid layer with uniform heat sources, the basic temperature profile can be written as [3]

$$\phi_0 = (T - T_2)/(T_1 - T_2) = (1 - z) + N_s(z - z^2) \quad (27)$$

where the heat source parameter N_s is defined in [3]. On the other hand, the fully-developed temperature profile for the present problem is given by

$$\phi_0 = (1 - \theta_f)/2 = (1 - z) + (-3Br)(z - 3z^2 + 4z^3 - 2z^4) \quad (28)$$

Based on eq. (27) and (28) for basic temperature profiles, one may conclude that the heat source parameter N_s [3] is

equivalent to the viscous dissipation parameter $(-3Br)$.

It is noted that the basic temperature profiles shown in Fig. 5 are somewhat similar to those shown in Fig. 2 of

[3]. The instability results for the fully-developed flow

are shown in Fig. 11 where the curve for $T_1 > T_2$, $N_s > 0$

shown in Fig. 3 of [3] is also displayed for comparison.

In Fig. 11, one sees that with viscous dissipation effect,

the fully-developed critical Rayleigh number depends on

Prandtl number. For a given Pr , one can clearly identify

the range of $(-3Br)$ where Ra^* is practically equal to that

of the linear temperature case ($Ra^* = 1708$). As $(-3Br)$

increases, Ra^* decreases, at first slowly and later rather

rapidly. In this respect, the present instability results

are qualitatively similar to the critical Rayleigh number

behavior for a horizontal fluid layer with heat sources [3].

Fig. 11 also shows the difference between the two instabi-

lity problems.

The viscous dissipation effects on fully developed

neutral stability curves are shown in Fig. 12 for $Pr = 100$

and $x = 5$. The viscous heating is clearly seen to be a

destabilizing influence. Within the range of present

investigation, the fully-developed instability results for

$Pr = 0.7$ and 10 do not differ appreciably from that of

$Pr = 100$.

5.5 Concluding Remarks

1. The viscous dissipative heating is an inherent

irreversible process and it is desirable to establish the range of parametric values for Brinkman number or Eckert number where the viscous heating is significant in forced convective flows. In this investigation, the viscous dissipation effects on Graetz problem [5] and on thermal instability problem [1] in the thermal entrance region of plane Poiseuille flow between two horizontal flat plates with heating from below are studied.

2. It is found that the destabilizing effect of viscous dissipation is significant for large Prandtl number fluid (say $Pr > 10$) but the effect is insignificant for small Prandtl number fluid (say $Pr \leq 0.7$).

3. The present instability results for the limiting case of $Br = 0$ agree with those of [1] for $Pe \rightarrow \infty$. For fully-developed flow, the destabilizing effect of viscous heating is found to be similar to that of internal heat generation in a horizontal fluid layer discussed in [3].

4. It is observed that the combined effect of Prandtl and Brinkman numbers in the perturbation eq. (24) may lead to a locally stabilizing effect resulting in a local maximum for Ra^* before reaching the fully-developed region.

5. In this study, the viscous dissipation effect in the perturbation eq. (24) is represented by the Eckert number ($Ec = Br/Pr$). In this connection, it may be of some interest to point out the relationship between the Eckert number and the viscous dissipation parameter, $Di = g\beta L/c_p$, appearing in Benard finite amplitude convection problem [4].

Interpreting $g_s(T_1 - T_2)L$ as (characteristic velocity)² and the characteristic temperature difference as $(T_1 - T_2)$, it is seen that the parameter $Di = g_s L / c_p$ in [4] is equivalent to the Eckert number for the present problem.

6. The present analysis is based on constant physical property assumption and the variable property effect is not considered. The complete numerical results are listed in Table 2 to 4.

7. With viscous dissipation effects, the entrance condition of uniform fluid temperature at $x = 0$ must be regarded as an approximate one.

CHAPTER VI

THERMAL ENTRANCE REGION HEAT TRANSFER FOR MHD LAMINAR FLOW IN PARALLEL-PLATE CHANNELS WITH UNEQUAL WALL TEMPERATURES

The problem of thermal entry heat transfer for Hartmann flow in parallel-plate channels with uniform but unequal wall temperatures considering viscous dissipation, Joule heating and axial conduction effects is approached by the eigenfunction expansion method. The series expansion coefficients for the nonorthogonal eigenfunctions are obtained by using a method for nonorthogonal series described by Kantorovich and Krylov [20]. Numerical results are obtained for the case with entrance condition parameter $\beta_0 = 1$ and open circuit condition $k = 1$. The parametric values of $Ha = 0, 2, 6, 10$ and $Br = 0, -1$ are considered for Hartmann and Brinkman numbers, respectively.

Nomenclature

a	=	one-half of channel height
\mathbf{B}, B_0	=	magnetic field induction vector and magnitude of applied magnetic field
Br	=	Brinkman number, $\mu_f u_m^2 / (k_c a)$
C_n, D_n	=	coefficients in the series expansion of τ_0 , see eq. (16)
c_p	=	specific heat at constant pressure
\mathbf{E}, E_0	=	electric field intensity vector and component
e_n	=	even and odd eigenfunctions
Ha	=	Hartmann number, $(\sigma / \mu_f)^{1/2} B_0 a$
h_1, h_2	=	local heat transfer coefficients at lower and upper plates
\mathbf{j}, j_y	=	electric current density vector and component
Λ	=	external loading parameter, $E_0 / (B_0 u_m)$
k	=	thermal conductivity
Nu_1, Nu_2	=	local Nusselt numbers, $h_1 a / k$ and $h_2 a / k$, respectively
P	=	fluid pressure
Pe	=	Peclet number; $PrRe$

- Pr = Prandtl number, $c_p \mu / k$
- q_1, q_2 = rates of heat transfer per unit area, $-k(dT/dx)_1 = q_1$, $-k(dT/dx)_2 = q_2$, respectively
- Re = Reynolds number, $\rho u_m a / \mu$
- T_1, T_2, T_b = fluid temperature, uniform entrance temperature, uniform but different lower and upper plate temperatures, respectively, bulk temperature and $(T_1 + T_2) / 2$
- u, \bar{u}, u^+ = axial, mean and dimensionless velocities, respectively
- \mathbf{u} = velocity vector
- x, z = axial and transverse coordinates
- x^+, z^+ = dimensionless coordinates
- λ_{\pm} = even and odd eigenvalues
- T_1^+, T_2^+ = dimensionless fluid, entrance and bulk temperatures, respectively
- θ = characteristic temperature difference $(T_2 - T_m)$, and dimensionless fluid temperatures, defined by eq. (10)
- μ = magnetic permeability and viscosity of fluid
- ρ = fluid density
- σ = electric conductivity

6.1. Introduction

Magnetohydrodynamic flow in the entrance region of a parallel-plate channel has been studied by many investigators in the past. The problem of laminar forced convection heat transfer for fully developed MHD flow (Bartmann flow) in the thermal entrance region of parallel-plate channels has also been studied for the case of constant wall temperature [1-6] and constant wall heat flux [7-8]. Similarly, the forced convection heat transfer of an MHD flow in the hydrodynamic entrance region of parallel-plate channels has been investigated for both uniform wall temperature [9-12] and uniform wall heat flux [13]. Combined forced and free convection heat transfer for MHD flow in vertical parallel-plate channels has been investigated extensively in recent years for the fully developed flow case. Recently, the problem of combined forced and free convection magnetohydrodynamic flow in the entrance region of a vertical parallel-plate channel was studied for both the constant wall heat flux and constant wall temperature boundary conditions [14].

For magnetohydrodynamic flow in the thermal entrance region of a horizontal parallel-plate channel heated from below, thermal instability problem concerning the onset of longitudinal vortex rolls [15] arises. After a critical value of Rayleigh number is reached, the flow assumes a three-dimensional character and consequently the published heat transfer results for thermal entrance region may no

longer be applicable. A literature survey shows that the published works on thermal entrance region heat transfer are concerned with the thermal boundary condition of either uniform wall temperature or uniform wall heat flux only at both upper and lower plates. The purpose of this study is to present the heat transfer results in the thermal entrance region of Hartmann flow between horizontal parallel plates at unequal but constant temperatures. The present problem deals with the basic flow solution required in the thermal instability analysis discussed in Chapter VII. In the analysis, the internal heat generation terms due to both Joule heating and viscous dissipation as well as axial conduction term [5] in the energy equation are retained. As noted in [16], heat transfer problem in the thermal entry region for fully developed laminar flow between parallel plates at uniform but unequal wall temperatures involves two distinct sets of eigenvalues related to odd and even sets of eigenfunctions, respectively.

6.2 Governing Equations

Consideration is given to a steady, viscous, incompressible, electrically-conducting fluid with constant physical properties flowing in a horizontal parallel-plate channel under the action of a constant, transverse magnetic field B_0 . The laminar velocity profile is already the fully developed Hartmann profile at a certain cross-section $x = 0$ (see Fig. 1) and the fluid temperature T_0 is constant

up to $X = 0$. For $X \geq 0$, the wall temperatures at lower and upper plates are maintained at constant values T_1 and T_2 , respectively. For the steady system under consideration, the basic equations are the equations of continuity, momentum and energy, Maxwell's equations and Ohm's Law. In vector notation, one obtains [17]

$$\nabla \cdot \bar{V} = 0 \quad (1)$$

$$(\bar{V} \cdot \nabla) \bar{V} = -\frac{1}{\rho} \nabla p + \nu \nabla^2 \bar{V} + \frac{1}{c} \bar{J} \times \bar{B} \quad (2)$$

$$\rho c_p (\bar{V} \cdot \nabla) T = k \nabla^2 T + \phi + \frac{1}{c} (\bar{J} \cdot \bar{J}) \quad (3)$$

$$\nabla \cdot \bar{B} = 0, \quad \nabla \times \bar{B} = \mu_e \bar{J}, \quad \nabla \cdot \bar{E} = 0, \quad \nabla \times \bar{E} = 0 \quad (4)$$

$$\bar{J} = \sigma (\bar{E} + \bar{V} \times \bar{B}) \quad (5)$$

where $\bar{V} = (U, 0, 0)$, $\bar{J} = (0, J_y, 0)$, $\bar{E} = (0, E_0, 0)$, $\bar{B} = (0, 0, B_0)$ for the present problem and $\phi =$ viscous dissipation function. The effect of the induced magnetic field B_x is assumed to be negligible in comparison with the applied field B_0 . Referring to the coordinate system shown in Fig. 1, the energy equation becomes

$$c_p U \frac{\partial T}{\partial X} = k \left(\frac{\partial^2 T}{\partial x^2} + \frac{\partial^2 T}{\partial z^2} \right) + \mu_f \left(\frac{dU}{dz} \right)^2 + \frac{J_y^2}{\sigma}$$

where $J_y = \tau(E_0 - UB_0)$ and the simplified version of the Ohm's law without Hall effect, is used. Introducing the dimensionless variables and parameters,

$$(X, Z) = [a](xPe, z), U = [U_m](u), \theta = (T - T_m)/(T_2 - T_m)$$

$$\theta_0 = (T_0 - T_m)/(T_2 - T_m), Re = \rho U_m a / \mu_f, Pe = Pr Re = \rho c_p U_m a / k,$$

$$Ha = (\tau / \mu_f)^{1/2} B_0 a, K = E_0 / B_0 U_m, Br = \mu_f U_m^2 / (k \theta_c)$$

$$\text{with } U_m = \int_{-a}^a U dz / (2a), T_m = (T_1 + T_2) / 2, \theta_c = T_2 - T_m = (T_2 - T_1) / 2,$$

equation (6) becomes

$$u \frac{\partial \theta}{\partial x} = \frac{1}{Pe^2} \left(\frac{\partial^2 \theta}{\partial x^2} + \frac{\partial^2 \theta}{\partial z^2} \right) + Br \left[\left(\frac{du}{dz} \right)^2 + Ha^2 (K - U)^2 \right] \quad (7)$$

The thermal boundary conditions at the thermal entrance, the walls and thermally fully developed region are

$$\theta(0, z) = \theta_0, \theta(x, 1) = 1, \theta(x, -1) = -1, \theta(x, z) = \theta_f \quad (8)$$

It is seen that viscous dissipation and Joule heating repre-

sent the heat source terms in the energy equation. For magnetohydrodynamic fully developed laminar flow, the well-known Hartmann solution [17] of equation (2) is

$$\begin{aligned} u &= Ha(\cosh Ha - \cosh Haz) / (Ha \cosh Ha - \sinh Ha) \\ &= C_1(\cosh Ha - \cosh Haz) \end{aligned} \quad (9)$$

where $C_1 = Ha / (Ha \cosh Ha - \sinh Ha)$. It is noted that when $Ha = 0$, one obtains $u = (3/2)(1 - z^2)$.

6.3 Solution of the Energy Equation

It is convenient to seek the solution of equation (7) in the following form.

$$\theta = \theta_f(z) + \theta_e(x, z) \quad (10)$$

where θ_f is the fully developed solution and θ_e is the excess temperature satisfying the following set of equations.

$$\frac{d^2 \theta_f}{dz^2} + Br \left[\left(\frac{du}{dz} \right)^2 + Ha^2 (K - u)^2 \right] = 0 \quad (11)$$

with the boundary conditions,

$$\theta_f(1) = 1, \quad \theta_f(-1) = -1 \quad (12)$$

$$u \frac{\partial \theta_e}{\partial x} = \frac{1}{Pe^2} \frac{\partial^2 \theta_e}{\partial x^2} + \frac{\partial^2 \theta_e}{\partial x^2} \quad (13)$$

with the entrance and boundary conditions,

$$\theta_e(0, z) = 0, \quad \theta_e(x, 1) = \theta_e(x, -1) = 0 \quad (14)$$

Substituting equation (9) into equation (11) and integrating twice, using the boundary condition, one obtains the solution for θ_f in the following form:

$$\theta_f = z + Br \left[\left(\frac{C_1^2}{4} \right) (\cosh 2Ha - \cosh 2Haz) + 2C_1 C_2 (\cosh Ha - \cosh Haz) + \left(\frac{C_2^2 Ha^2}{2} \right) (1 - z^2) \right] = z + Br f(z) \quad (15)$$

where $C_2 = K - C_1 \cosh Ha$ and $f(z)$ = terms inside square brackets. When $Ha = 0$, one obtains $\theta_f = z + (3Br/4)(1 - z^4)$.

The general solution of equation (13) can be constructed

in the form of infinite series as

$$\theta_e = \sum_{n=1}^{\infty} C_n E_n(z) \exp(-\beta_n x) + \sum_{n=1}^{\infty} D_n O_n(z) \exp(-\gamma_n x) \quad (16)$$

where β_n , γ_n and E_n , O_n are the even and odd eigenvalues and eigenfunctions, respectively, of the following characteristic equation and the associated boundary conditions.

$$\frac{d^2 E_n}{dz^2} + \left(\beta_n u + \frac{\beta_n^2}{Pe^2} \right) E_n = 0, \quad E_n(\pm 1) = 0 \quad (17)$$

$$\frac{d^2 Q_n}{dz^2} + \left(\gamma_n u + \frac{\gamma_n^2}{Pe^2} \right) Q_n = 0, \quad Q_n(\pm 1) = 0 \quad (18)$$

It is noted that as $Pe \rightarrow \infty$, equations (17) and (18) reduces to the classical Sturm-Liouville systems typified by the Graetz-type problem neglecting axial conduction term. The eigenvalues and the corresponding eigenfunctions are determined in this study by solving equations (17) and (18) using the fourth-order Runge-Kutta method [18]: Two hundred equal steps are employed and the boundary conditions for E_n and Q_n at the starting point are $E_n(0) = 1$, $dE_n(0)/dz = 0$ and $Q_n(0) = 0$, $dQ_n(0)/dz = 1$, respectively. The eigenvalues are improved by using variable secant method [19] which requires assuming two trial values for β_n or γ_n with the difference of say 0.1 at the start. The even eigenvalues β_n are listed in [6] for $Ha = 2, 6, 10$ and $Pe = 1, 10, 10^2$, and can be used as the initial values in this study. The number of iterations required to reach $E_n(1)$ or $Q_n(1) < 10^{-8}$ depends on the initial value of β_n or γ_n but usually it takes only 5 to 7 iterations. The spectrum of eigenvalues is checked by plotting $(\beta_n)^{1/2}$ or $(\gamma_n)^{1/2}$ versus n .

The series expansion coefficients C_n and D_n remain to

be determined by the application of the entrance condition. Since the axial conduction term is retained, the eigenfunctions lack the property of orthogonality and the eigenfunction expansion technique for Sturm-Liouville system no longer applies. To overcome the difficulty the method for nonorthogonal series described in [20] is used in this study. From the thermal entrance condition at $z = 0$; one obtains

$$\sum_{n=1}^{\infty} C_n E_n(z) + \sum_{n=1}^{\infty} D_n \theta_n(z) = \theta_0 - \text{Brf}(z) - z \quad (19)$$

Here, one notes that $[\theta_0 - \text{Brf}(z)]$ is an even function and z is an odd function. After multiplying both sides of equation (19) by $E_i(z)$ and integrating it, one obtains a system of N equations by taking the first N terms of the series.

$$\sum_{n=1}^N C_n \int_{-1}^1 E_n(z) E_i(z) dz = \int_{-1}^1 [\theta_0 - \text{Brf}(z)] E_i(z) dz, \quad (i = 1, 2, \dots, N) \quad (20)$$

In practice, the lower limit of the integral may be replaced by 0 and Simpson's rule (IBM-SSP) is used for numerical integration. The system of N linear simultaneous equations with N unknown coefficients is solved by Gauss-Seidel method

(IBM-SSP). Similarly, for the odd coefficients D_n , one obtains

$$\sum_{n=1}^N D_n \int_0^1 \theta_n(z) \theta_i(z) dz = \int_0^1 (-z) \theta_i(z) dz, \quad i=1, 2, \dots, N \quad (21)$$

Considering the case of heating from below ($T_1 > T_2$), the expressions for the local Nusselt numbers Nu_1 and Nu_2 at the lower and upper plates, respectively, are defined by

$$Nu_1 = \frac{h_1 a}{k} = \frac{a}{k} \frac{q_1}{(T_1 - T_b)} = \frac{1}{1 + \theta_b} \left(\frac{\partial \theta}{\partial z} \right)_{z=-1} \quad (22)$$

$$Nu_2 = \frac{h_2 a}{k} = \frac{a}{k} \frac{q_2}{(T_b - T_2)} = \frac{1}{1 - \theta_b} \left(\frac{\partial \theta}{\partial z} \right)_{z=1} \quad (23)$$

where the bulk temperature θ_b is

$$\theta_b = \frac{\int_{-1}^1 \theta dz}{\int_{-1}^1 dz} \quad (24)$$

The following limiting expressions corresponding to the fully developed condition ($x \rightarrow \infty$) are also of interest

$$\begin{aligned}
 \text{bf} &= (Br/2) \left[\frac{C_1^2}{2} \cosh 2Ha + \frac{C_1^3}{12} (3 + \cosh 2Ha) \right. \\
 &+ 4 C_1^2 C_2 + \frac{1}{2} \cosh 2Ha - \frac{3}{4Ha} \sinh 2Ha + C_2^2 Ha \left. \right] \\
 &- C_1 \cosh Ha \left(\frac{1}{2} + \frac{2}{Ha^2} \right) + \frac{C_1}{Ha} \left(1 + \frac{2}{Ha^2} \right) \sinh Ha. \quad (25)
 \end{aligned}$$

$$\begin{aligned}
 Nu_{1f} &= \left[1 - BrHa \left(\frac{C_1^2}{2} \sinh 2Ha + 2C_1 C_2 \sinh Ha \right. \right. \\
 &\left. \left. + C_2^2 Ha \right) \right] / (1 - \text{bf}) \quad (26)
 \end{aligned}$$

$$\begin{aligned}
 Nu_{2f} &= \left[1 + BrHa \left(\frac{C_1^2}{2} \sinh 2Ha + C_1 C_2 \sinh Ha \right. \right. \\
 &\left. \left. + C_2^2 Ha \right) \right] / (1 + \text{bf}) \quad (27)
 \end{aligned}$$

6.4 Numerical Results and Discussion

The present problem involves five parameters (Pe , Ha , K , Br , θ_0) and the range of variation of each parameter which is of practical interest in this study is $Pe = 10$, $Ha = 0 \sim 10$, $K = 0 \sim 2$, $Br = 0 \sim -1$, $\theta_0 = -\infty \sim \infty$, respectively. Because of the number of parameters present, computations are made for the parametric values of $Pe = 10, 10^2$, $Ha = 0, 2, 6, 10$, $K = 1$ (open circuit condition), $Br = 0, -1$ and $\theta_0 = 1$ ($T_0 = T_2$) only. These are designed to study the

axial conduction, Hartmann number and viscous dissipation effects on thermal entrance region heat transfer.

The eigenvalues, λ_n , τ_n and the coefficients C_n , D_n for $Pe = 10, 10^3$, and $Br = 0, -1$ are listed in Tables 1 to 4 for the cases of $Ha = 0, 2, 6$ and 10 , respectively, with $\gamma_0 = 1$ and $K = 1$. The eigenvalues λ_n and τ_n are independent of the values for γ_0 and K . The numerical values of C_n are a function of γ_0 and K , as well as Br . The values of D_n are independent of Br and a function of γ_0 and K only as can be seen from equation (21).

The developing temperature profiles ($\theta = \frac{1}{2}(1 - \dots)$) versus $z' = \frac{1}{2}(z + 1)$ at various axial positions in the thermal entrance region are presented in Figs. 1 to 5. With $K = 1$ (the lowest current or open circuit case), the Joule heating is minimum and the viscous dissipation produces more heating than the Joule heating. Fig. 1 shows that with $Pe = 10, Ha = 0, Br = 0$, a fully developed linear temperature profile is already attained at $x = 5.0$. It is found that twelve eigenvalues are not sufficient to yield convergent solution near the thermal entrance $x = 10^{-3}$. The case of $Br = -1$ (heating from below) represents dominant overall dissipation and Brinkman effect can be seen clearly by a comparison between Figs. 1 and 2. Fig. 2 also shows that viscous heating effect is particularly appreciable near the upper and lower walls. Similar plottings for $Pe = 10$ and $Ha = 2$ are shown in Figs. 3 and 4 for $Br = 0$ and -1.0 , respectively. With $Br = 0$, Hartmann number effect can be

seen by comparing Fig. 3 with Fig. 1 and one notes that thermal entrance length does not appear to be affected by magnetic field at $Ha = 2$. Fig. 4 shows that dissipation effects are further magnified by Joule heating at $Ha = 2$. The behavior of fully developed temperature profile shown in Fig. 4 can be understood by invoking the membrane analogy for equation (11). In equation (15), the term $Br f(z)$ apparently represents the dissipation effects. The Hartmann number effects on developing temperature profiles (θ) and on bulk temperature distribution (θ_b) are further illustrated in Figs. 5 ($Pe = 10$) and 6 ($Pe = 100$), respectively. One notes that the difference between the axial bulk temperature distributions for $Pe = 10$ and 100 can hardly be distinguished graphically.

Of particular practical interest in this study are the effects of Hartmann number on local Nusselt number variations at the lower and upper plates and the results are presented in Figs. 7 and 8 for $Br = 0$ and -1 , respectively, and in Table 5 and 6. The effect of magnetic field on local heat transfer is clearly seen in Fig. 7 for $Br = 0$. At $Pe = 100$, the axial conduction effect is practically negligible and the local Nusselt number Nu_1 at the lower plate increases with the increase of Ha . Similar effect also exists at the upper plate but the local Nusselt number is seen to be zero up to a certain axial distance ($x \approx 8 \times 10^{-2}$). At $Pe = 10$, the axial conduction effect is quite pronounced and the local Nu_1 decreases as Ha increases up

to $x = 9 \times 10^{-3}$ but further downstream the trend reverses and is similar to that of $Pe = 100$. At the upper plate, the difference in local Nusselt numbers (Nu_1) between $Pe = 10$ and 100 is very small but the case of $Pe = 100$ has higher value for a given Ha . It is seen clearly that the axial conduction effect disappears completely at $x = 1$.

With $Br = -1$, the local Nusselt number behavior is more complicated than that of $Br = 0$. In Fig. 8, the zero Nusselt number signifies a change in the direction of the heat transfer at the wall. At $Br = -1$, the viscous dissipation effect is dominant and the Hartmann number effect is similar for $Pe = 10$ and 100 . The local Nu_1 decreases as Ha increases and the trend is opposite to that of the case $Pe = 100$, $Br = 0$. The merging of the two curves for $Pe = 10$ and 100 with the same value of Ha at a certain axial distance x indicates the vanishing axial conduction effect. The behavior of the fully developed Nusselt number Nu_{1f} can be explained from the fully developed temperature profiles at $x = 5$ shown in Fig. 5 where the fluid temperature is seen to be higher than the lower wall temperature. Because of the viscous dissipation effect, the local Nusselt number Nu_2 at the upper plate is not zero near the thermal entrance $x = 0$ and the Nusselt number Nu_2 decreases monotonically toward a fully developed value depending on Ha . The effect of Ha on fully developed Nusselt numbers Nu_2 can be explained from the corresponding temperature profiles shown in Fig. 5.

5. Concluding Remarks

(1) The present method of computation for the series expansion coefficients is different from that of [5]. The present computational procedure is very straightforward and leads to accurate results. The method of solution is valid for any values of β_0 and δ .

(2) The odd eigenvalues listed in tables 1 to 4 take values between those of the even eigenvalues. The even eigenvalues check well with those reported in [5]. The numerical eigenvalues of γ_n and γ_{0n} for the case of $Pe = 1$ and $\delta = 0$ also agree with the corresponding equivalent values ($\gamma_n = (2/3) \gamma_{0n}$, $\gamma_{0n} = (2/3) \gamma_{0n}$) listed in Table 1 of [16].

(3) For the present formulation including viscous dissipation effect, the entrance condition of uniform fluid temperature at $x = 0$ must be regarded as an approximate one. Consequently, numerical calculation is not made for $Pe > 10$. In this respect, the present numerical results as well as the published results [2,5,8] must be understood under this light. In general, if one includes both viscous dissipation and axial heat conduction effects in the classical Graetz problem (thermal entrance region problem), even the entrance condition of uniform fluid temperature at $x = 0$ must be regarded as an approximate one. In the physical problem, the specification of uniform entrance temperature and the inclusion of viscous dissipation effect in the problem formulation are seen to be incompatible to some extent.

4. The present solution serves as a basic flow solution for thermal instability of Hartmann flow in horizontal parallel-plate channel heated from below, which will be discussed in Chapter VII.

5. Within the range of parametric values studied, thermal entrance length does not appear to be affected by magnetic field up to $Ha = 10$. It is noted that the heat transfer results are independent of Prandtl number. In this study, the numerical computation is limited to $Ha \leq 10$ in order to check the even eigenvalues against those given in [5]. However, no computational difficulty is expected for $Ha > 10$. One notes that the influence of the flattening Hartmann velocity profile on heat transfer continues with further increase of the Hartmann number. The flat velocity distribution for $Ha \rightarrow \infty$ or slug flow is practically approached at $Ha \approx 20$.

CHAPTER VII

THERMAL INSTABILITY OF HARTMANN FLOW IN THE THERMAL ENTRANCE REGION OF HORIZONTAL PARALLEL- PLATE CHANNELS HEATED FROM BELOW

The onset of instability in the form of longitudinal vortices for fully developed Hartmann laminar flow in the thermal entrance region of horizontal parallel-plate channels is investigated by a numerical method for the case with a uniform vertical magnetic field and heating from below. Numerical results are obtained for $Pr = 0.7, 0.01$, $Pe = 10, 100, \infty$, $Br = 0, -1$, and $Ha = 0, 2, 6, 10$. The effects of Prandtl, Peclet (axial conduction), Brinkman (viscous dissipation and Joule heating) and Hartmann numbers on thermal instability of magnetohydrodynamic flow are studied.

Nomenclature

a	= dimensionless wave number
\vec{B}	= magnetic field induction vector, (0,0, B_0)
Br	= Brinkman number, $\mu_f U_m^2 / (k\theta_c)$
\vec{b}	= dimensionless perturbation vector of impressed magnetic field, (b_x, b_y, b_z)
C_n, D_n	= coefficients in the series expansion of θ_e
c_p	= specific heat at constant pressure
D	= $dydz$
<hr/>	
\vec{E}	= electric field intensity vector, (0, E_0 ,0)
E_n, O_n	= even and odd eigenfunctions
\vec{e}	= dimensionless perturbation vector of electric field, (e_x, e_y, e_z)
Gr	= Grashof number, $g\beta(\Delta T)\ell^3/\nu^2$
g	= gravitational acceleration
Ha	= Hartmann number, $(\mu_f)^{1/2} B_0 \ell$
\vec{J}	= electric current density vector, (0, J_y ,0)
J_0	= $\sigma B_0 U_m J$
\vec{j}	= dimensionless perturbation vector of \vec{J} , (j_x, j_y, j_z)

K	=	external loading parameter, $E_0/(B_0 U_m)$
k	=	thermal conductivity
L	=	a distance between two infinite horizontal flat plates
	=	$L/2$
M	=	number of divisions in z direction
P, P_b	=	fluid pressure ($P_b + P'$) and pressure for basic flow
Pe	=	Peclet number, $PrRe$
Pr	=	Prandtl number, $c_p \mu_f / k$
p	=	dimensionless perturbation pressure, $P' / (\rho U_m^2)$
Ra	=	Rayleigh number, $g\beta\Delta T L^3 / \nu\alpha$
Re	=	Reynolds number, $\rho U_m L / \mu_f$
Rm	=	magnetic Reynolds number, $U_m L / (1/\mu_e \sigma)$
T, T_b, T_0	=	fluid temperature ($T_b + \theta'$), fluid temperature of basic flow and uniform entrance temperature
T_1, T_2, T_m	=	uniform but different lower and upper plate temperatures, and $(T_1 + T_2)/2$
U_b, U_m, u_b	=	axial, mean and dimensionless velocities of basic flow
u, v, w	=	dimensionless perturbation velocity components

V, V_b, V'	= velocity vector ($V_b + V'$), basic velocity vector ($U_b, 0, 0$) and perturbation velocity vector (U', V', W')
X, Y, Z	= Cartesian coordinates with origin at lower plate
x, y, z	= dimensionless coordinates
\bar{x}, \bar{z}	= transformed coordinates, $x/Pe, \bar{z} = z$
Z', z'	= dimensional and dimensionless transverse coordinates with origin at centre of channel
α	= thermal diffusivity
β	= coefficient of thermal expansion
<hr/>	
β_n, γ_n	= even and odd eigenvalues
$\theta, \theta_b, \theta_0$	= dimensionless perturbation, basic flow and entrance temperatures
$\theta_c, \theta_e, \theta_f$	= characteristic temperature difference $(T_2 - T_m) = (T_2 - T_1)/2$, and dimensionless fluid temperatures defined by eq. (7)
μ_e, μ_f	= magnetic permeability and viscosity of fluid
ν	= kinematic viscosity
ρ	= fluid density
σ	= electric conductivity
Φ	= viscous dissipation function

- U, θ = dimensionless basic velocity and temperature profiles, U_b/U_m and $(T_b - T_2)/\Delta T$
- ψ = dimensionless stream function
- ΔT = $(T_1 - T_2) = -2\theta_c$

Superscripts and Subscripts

- ' = perturbation quantity
- + = amplitude of disturbance quantity
- * = transformed perturbation variable or critical value
- b = basic quantity in unperturbed state
- k = space subscript of a grid point
-

7.1 Introduction

In recent years, the problem of the laminar forced convection for fully developed MHD laminar flow in the thermal entrance region of a parallel-plate channel has been studied by many investigators for the thermal boundary conditions of both uniform wall heat flux and constant wall temperature. The literature on the subject is well reviewed in [1,2] and in Chapter VI. It is known that when a horizontal fluid layer is subjected to an adverse temperature gradient, a top-heavy situation results and the system is potentially unstable due to the buoyancy forces. With a superposed fully developed laminar flow between two horizontal flat plates, heated from below, the onset of the secondary flow in the form of longitudinal vortices [3-7] is characterized by a critical Rayleigh number. With the appearance of the vortex rolls, the flow takes on a three-dimensional character and the heat transfer rate is expected to increase with the Rayleigh number. Thus, it is of practical interest to determine the conditions for the onset of secondary flow.

The effects of a vertical, uniform magnetic field on the thermal instability of horizontal stationary fluid layers were studied theoretically by Thompson [8] and Chandrasekhar [9,10] and experimentally by Nakagawa [11-14]. The thermal instability of a magnetofluid in a vertical rectangular channel heated from below was investigated by Yu [15] quoting the related references. The thermal instabi-

lity of a Hartmann flow in the thermal entrance region of a horizontal parallel-plate channel with heating from below does not appear to have been studied in the past. The purpose of this study is to determine the conditions marking the onset of longitudinal vortex rolls in the said passage where the two plates are maintained at uniform but different surface temperatures. The present study can be regarded as a first step toward investigating the change of heat transfer rate due to the thermal instability for a Hartmann flow and represents an extension of the thermal instability problem for a confined horizontal fluid layer studied by Thompson [8] and Chandrasekhar [9,10] to the case with a superposed fully developed laminar flow. The basic velocity and temperature fields in the thermal entrance region of the channel required for the present thermal instability analysis are reported in Chapter VI.

7.2 Formulation of the Thermal Instability Problem

7.2.1 Basic Flow and Temperature Fields

Consideration is given to a Hartmann flow between two horizontal flat plates under the action of a homogeneous transverse magnetic field B_0 and heated from below. The basic equations of motion, of Maxwell, and of energy appropriate to the thermal entrance region heat transfer problem [3] are:

$$\nabla \cdot \bar{V}_b = 0 \quad (1)$$

$$(\mathbf{V}_b \cdot \nabla) \mathbf{V}_b = \frac{1}{\rho} \nabla p_b + \nu \nabla^2 \mathbf{V}_b + \frac{1}{c} \mathbf{J} \times \mathbf{B} \quad (2)$$

$$\nabla \cdot \mathbf{B} = 0, \quad \nabla \times \mathbf{B} = \mu_p \mathbf{J}, \quad \nabla \cdot \mathbf{E} = 0, \quad \nabla \times \mathbf{E} = 0, \quad \mathbf{J} = \sigma (\mathbf{E} + \mathbf{V}_b \times \mathbf{B}) \quad (3)$$

$$\rho c_p (\mathbf{V}_b \cdot \nabla) T_b = k \nabla^2 T_b + \dot{E} + \frac{1}{\rho} (\mathbf{J} \cdot \mathbf{J}) \quad (4)$$

where $\mathbf{V}_b = (U_b, 0, 0)$, $\mathbf{J} = (0, J_y = \sigma(E_0 - UB_0), 0)$, $\mathbf{E} = (0, E_0, 0)$, $\mathbf{B} = (0, 0, B_0)$, $\dot{E} = \nu_f (dU_b/dZ')^2$ and $\nabla^2 = \partial^2/\partial X^2 + \partial^2/\partial Z'^2$ in energy equation (4) and the coordinate system is defined in Fig. 1. The boundary conditions are:

$$U_b(0, \pm z) = 0, \quad T_b(0, Z') = T_0, \quad T_b(X, -z) = T_1, \quad T_b(X, z) = T_2 \quad (5)$$

Introducing the following dimensionless variables and physical parameters, $(X, Z') = [\lambda](xRe, z')$, $U_b = [U_m](u_b)$, $\theta_b = (T_b - T_m)/(T_2 - T_m)$, $\theta_0 = (T_0 - T_m)/(T_2 - T_m)$, $Re = \rho U_m \lambda / \mu_f$, $Pe = PrRe = \rho c_p U_m \lambda / k$, $Ha = (\sigma / \mu_f)^{1/2} B_0 \lambda$, $K = E_0 / (B_0 U_m)$, $Br = \mu_f U_m^2 / (k \theta_c)$, where $U_m = \int_{-z}^z U_b dZ' / (2z)$, $T_m = (T_1 + T_2)/2$, $\theta_c = T_2 - T_m = (T_2 - T_1)/2$, the well known Hartmann solution [16] for equation (2) and the solution of energy equation (4) considering both the viscous dissipation and axial conduction effects can be written as

$$u_b = Ha(\cosh Ha - \cosh Ha z') / (Ha \cosh Ha - \sinh Ha) \\ = C_1(\cosh Ha - \cosh Ha z') \quad (6)$$

$$\theta_b = \theta_f(z') + \theta_e(x, z') \quad (7)$$

where $\theta_f = z' + Br[(C_1^2/4)(\cosh 2Ha - \cosh 2Ha z') + 2 C_1 C_2(\cosh Ha - \cosh Ha z) + (C_2^2 Ha^2/2)(1 - z'^2)]$, $C_2 = K - C_1 \cosh Ha$, $\theta_e = \sum_{n=1}^{\infty} C_n E_n(z') \exp(-B_n x) + \sum_{n=1}^{\infty} D_n O_n(z') \exp(-\gamma_n x)$. The details of the infinite series solution for θ are given in Chapter VI and the expression for θ is given here for reference purpose only. At this point, it is convenient to shift the coordinate origin to the bottom plate for the instability problem and one obtains $z = \frac{1}{2}(z' + 1)$ and the developing temperature profile $\phi_0 = \frac{1}{2}(1 - \theta_b)$.

7.2.2 Perturbation Equations

In order to study the thermal instability concerned with the onset of secondary flow in the form of longitudinal vortices for the horizontal Hartmann flow heated from below, the perturbation quantities are superimposed on the basic quantities as

$$\vec{V} = \vec{V}_b + \vec{V}' = [U_b(z) + U', V', W'], \quad T = T_b + \theta', \quad P = P_b + P''$$

$$\begin{aligned}\bar{E} &= \bar{E}_b + \bar{e}' = (e_x', E_0 + e_y', e_z'), \quad \bar{B} = \bar{B}_b + \bar{b}' \\ &= (b_x', b_y', B_0 + b_z')\end{aligned}\quad (8)$$

$$\bar{J} = \bar{J}_b + \bar{j}' = (j_x', J_0 + j_y', j_z')$$

The above perturbation quantities are considered to be in the steady state and are a function of space variables X , Y and Z only. After applying the linear stability theory and using Boussinesq approximation, the perturbation equations become:

$$\frac{\partial U'}{\partial X} + \frac{\partial V'}{\partial Y} + \frac{\partial W'}{\partial Z} = 0 \quad (9)$$

$$\rho(U_b \frac{\partial U'}{\partial X} + W' \frac{dU_b}{dZ}) = - \frac{\partial P'}{\partial X} + \mu_f \nabla^2 U' + (J_0 b_z' + B_0 j_y') \quad (10)$$

$$\rho U_b \frac{\partial V'}{\partial X} = - \frac{\partial P'}{\partial Y} + \mu_f \nabla^2 V' - B_0 j_x' \quad (11)$$

$$\rho U_b \frac{\partial W'}{\partial X} = - \frac{\partial P'}{\partial Z} + \mu_f \nabla^2 W' - J_0 b_x' + \rho g \beta \theta' \quad (12)$$

$$\begin{aligned}\rho c_p (U_b \frac{\partial \theta'}{\partial X} + U' \frac{\partial T_b}{\partial X} + W' \frac{\partial T_b}{\partial Z}) &= k \nabla^2 \theta' \\ &+ 2\mu_f \left(\frac{dU_b}{dZ}\right) \left(\frac{\partial U'}{\partial Z}\right) + 2 \frac{J_0}{\sigma} j_y'\end{aligned}\quad (13)$$

$$\begin{aligned}
 j_x' &= \sigma(e_x' + B_0 V'), \quad j_y' = \sigma(e_y' - B_0 U' \\
 &\quad - U_b b_z'), \quad j_z' = \sigma(e_z' + U_b b_y')
 \end{aligned}
 \tag{14}$$

$$\nabla \cdot \bar{e}' = 0, \quad \nabla \times \bar{e}' = 0, \quad \nabla \cdot \bar{b}' = 0, \quad \nabla \times \bar{b}' = \mu_e \bar{j}' \tag{15}$$

where $\nabla^2 = \partial^2/\partial X^2 + \partial^2/\partial Y^2 + \partial^2/\partial Z^2$.

Introducing the following non-dimensional quantities and physical parameters,

$$(X, Y, Z) = L(x, y, z), \quad (U', V', W') = U_m(u, v, w), \quad \theta' = (\Delta T)\theta$$

$$P' = (\rho U_m^2) p, \quad (b_x', b_y', b_z') = B_0 (b_x, b_y, b_z), \quad (e_x', e_y', e_z')$$

$$= E_0 (e_x, e_y, e_z), \quad (j_x', j_y', j_z') = \sigma B_0 U_m (j_x, j_y, j_z)$$

$$Gr = \frac{g\beta(\Delta T)\ell^3}{\nu^2}, \quad Rm = U_m \ell / (\nu/\mu_e \sigma)$$

and noting that $U_b = U_m \phi_u$, $T_b - T_2 = (\Delta T)\phi_\theta$, $J_0 = \sigma B_0 U_m J = \sigma B_0 U_m (K - \phi_u)$, $\Delta T = (T_1 - T_2) = -2\theta_c$, the perturbation equations become

$$\frac{\partial u}{\partial x} + \frac{\partial v}{\partial y} + \frac{\partial w}{\partial z} = 0 \tag{16}$$

$$\phi_u \frac{\partial u}{\partial x} + w \frac{d\phi_u}{dz} = - \frac{\partial p}{\partial z} + \frac{1}{2Re} \nabla^2 u + \frac{2Ha^2}{Re} (Jb_z + j_y) \quad (17)$$

$$\phi_u \frac{\partial v}{\partial x} = - \frac{\partial p}{\partial y} + \frac{1}{2Re} \nabla^2 v - \frac{2Ha^2}{Re} j_x \quad (18)$$

$$u \frac{\partial w}{\partial x} = - \frac{\partial p}{\partial z} + \frac{1}{2Re} \nabla^2 w - \frac{2Ha^2}{Re} Jb_x + \frac{2Gr}{Re^2} \theta \quad (19)$$

$$2Pe[\phi_u \frac{\partial \theta}{\partial x} + u \frac{\partial \phi_\theta}{\partial x} + w \frac{\partial \phi_\theta}{\partial z}] = \nabla^2 \theta - Br[\frac{d\phi_u}{dz} \frac{du}{dz} + 4Ha^2 Jj_y] \quad (20)$$

$$j_x = Ke_x + v, j_y = Ke_y - u - \phi_u b_z, j_z = Ke_z + \phi_u b_y \quad (21)$$

$$\nabla \cdot \bar{e} = 0 \quad (a), \nabla X \bar{e} = 0 \quad (b), \nabla \cdot \bar{b} = 0 \quad (c), \nabla X \bar{b} = 2Rm \bar{j} \quad (d) \quad (22)$$

Here it is understood that the operators ∇^2 and ∇ are dimensionless.

After eliminating u, v, p and using continuity equation, the three momentum equations can be combined into a single equation as

$$\begin{aligned} \nabla^2 \nabla^2 w - 4Ha^2 \frac{\partial^2 w}{\partial z^2} - 2Re[\phi_u \frac{\partial}{\partial x} \nabla^2 w - \frac{\partial w}{\partial x} \frac{d^2 \phi_u}{dz^2}] = - \frac{4Gr}{Re} \nabla_1^2 \theta \\ + 4Ha^2 [J(\nabla_1^2 b_x + \frac{\partial^2 b_z}{\partial x \partial z}) - 2 \frac{d\phi_u}{dz} \frac{\partial b_z}{\partial x} - \phi_u \frac{\partial^2 b_z}{\partial x \partial z}] \quad (23) \end{aligned}$$

where $\nabla_1^2 = \partial^2 / \partial x^2 + \partial^2 / \partial y^2$.

From equations (20), (23) and noting further that for vortex-type instability $\partial p / \partial x = 0$, one has 7 unknowns u , w , θ , b_x , b_z , j_y and e_y . Consequently, one needs additionally one momentum equation, Ohm's law, two magnetic induction equations and one electric field equation as follows.

$$\nabla^2 u - 2\text{Re} \phi_u \frac{\partial u}{\partial x} = 2\text{Re} w \frac{d\phi_u}{dz} - 4\text{Ha}[(K - \phi_u)b_z + j_y] \quad (24)$$

$$j_y = Ke_y - u - \phi_u b_z \quad (25)$$

$$\nabla^2 b_x - 2\text{Rm} \phi_u \frac{\partial b_x}{\partial x} = -2\text{Rm} \left[\frac{\partial u}{\partial z} + \frac{d\phi_u}{dz} b_z \right] \quad (26)$$

$$\nabla^2 b_z - 2\text{Rm} \phi_u \frac{\partial b_z}{\partial x} = -2\text{Rm} \frac{\partial w}{\partial z} \quad (27)$$

$$\nabla^2 e_y = 0 \quad (28)$$

The boundary conditions are

$$u = w = \frac{\partial w}{\partial z} = \theta = 0 \quad \text{at } z = 0, 1 \quad (\text{rigid walls})$$

$$j_z = 0 \quad \text{at } z = 0, 1 \quad (\text{non-conducting walls}) \quad (29)$$

For the disturbances in the form of longitudinal vortices, one may assume the disturbance form [6] $f = f^+(z)e^{iay}$ for the disturbance quantities. The set of equations then becomes:

$$(D^2 - a^2)^2 w^+ - 4Ha^2 D^2 w^+ = 4Ha^2 [(K - \phi_u)(-a^2)b_x^+] + \frac{4Gr}{Re} a^2 \theta^+ \quad (30)$$

$$(D^2 - a^2)u^+ - 4Ha^2 u^+ = 2Re \frac{d\phi_u}{dz} w^+ - 4Ha^2 [(K - 2\phi_u)b_z^+] \quad (31)$$

$$(D^2 - a^2)\theta^+ = 2Pe[u^+ \frac{\partial \phi_\theta}{\partial x} + w^+ \frac{\partial \phi_\theta}{\partial z}] + Br[\frac{d\phi_u}{dz} Du^+ - 4Ha^2 (K - \phi_u)j_y^+] \quad (32)$$

$$j_y^+ = Ke_y^+ - u^+ - \phi_u b_z^+ \quad (33)$$

$$(D^2 - a^2)b_x^+ = -2Rm(Du^+ + \frac{d\phi_u}{dz} b_z^+) \quad (34)$$

$$(D^2 - a^2)b_z^+ = -2Rm Dw^+ \quad (35)$$

$$(D^2 - a^2)e_y^+ = 0 \quad (36)$$

where $D = d/dz$, $V^2 = D^2 - a^2$ and $V_1^2 = -a^2$. A study of the electromagnetic boundary conditions is now in order. When the magnetic Reynolds number Rm is very small, an order of magnitude analysis reveals that the right-hand sides of equations (34) and (35) can be neglected. From Maxwell's equations and equations (34), (36) and (29) it can be shown that $e_x^+ = e_y^+ = e_z^+ = b_x^+ = 0$ for the whole domain and the details are given in Appendix IV. It is convenient to introduce the transformations $x = Pe\bar{x}$, $z = \bar{z}$, $u^+ = Reu^*$, $w^+ = w^*$, $\theta^+ = Pe\theta^*$, $j_y^+ = Rej_y^*$, $b_z^+ = Rmb_z^*$ and one obtains

$$[(D^2 - a^2)^2 - 4Ha^2D^2]w^* = 4Ra a^2\theta^* \quad (37)$$

$$[(D^2 - a^2) - 4Ha^2]u^* = 2 \frac{d\phi_u}{d\bar{z}} w^* - [4Ha^2(K - 2\phi_u) \frac{Rm}{Re} b_z^*] \quad (38)$$

$$(D^2 - a^2)\theta^* = 2 \left[\frac{u^*}{Pr} \frac{\partial \phi_\theta}{\partial \bar{x}} + w^* \frac{\partial \phi_\theta}{\partial \bar{z}} \right] + \frac{Br}{Pr} \left[Re \frac{d\phi_u}{d\bar{z}} Du^* - 4Ha^2(K - \phi_u) j_y^* \right] \quad (39)$$

$$j_y^* = -u^* - [\phi_u \frac{Rm}{Re} b_z^*] \quad (40)$$

Since Rm/Re is very small, the terms involving Rm/Re in equations (38) and (40) can be neglected [17] entirely in

comparison with the other terms. Thus, one sees that the present eigenvalue problem can be solved independently of the boundary conditions on the magnetic field. The physical parameters are seen to be Pr , Pe , Br , Ha and Ra . The boundary conditions are

$$u^* = w^* = Dw^* = \theta^* = 0 \quad \text{at } z = 0, 1 \quad (41)$$

It is instructive to note that the term $4a^2 Ra \theta^*$ in equation (37) represents the effect of buoyancy forces and is balanced by the viscous term $(D^2 - a^2)^2 w^*$ and the Lorentz force term $(-4Ha^2 D^2 w^*)$. In equation (38) the inertia term $w^* \partial \phi_u / \partial z$ is caused by the coupled effect of upward disturbance velocity w^* and the vertical gradient of basic velocity profile function and is seen to be balanced by the viscous term $(D^2 - a^2) u^*$ and the Lorentz force term $(-4Ha^2 u^*)$. Furthermore, in energy equation (39) there are two convective motions; one is the convective term caused by the coupled effect of velocity disturbance u^* and basic temperature gradient $\partial \phi_\theta / \partial x$ in the main flow direction, and the other is the convective term caused by velocity disturbance w^* and the basic temperature gradient $\partial \phi_\theta / \partial z$ in the vertical direction. It is seen that the two convective terms, a viscous dissipation term $(Br \cdot Re / Pr) \cdot d\phi_u / dz \cdot Du^*$, and a Joule heating term $[(Br / Pr) \cdot (-4Ha^2 (K - \phi_u)) j_y^*]$ are balanced by the conduction term $(D^2 - a^2) \theta^*$. Equation (40)

shows that the current disturbance amplitude in y-direction is simply equal to the negative velocity disturbance amplitude in x-direction. One also notes that the terms involving Ha^2 are preceded by a negative sign suggesting that the transverse magnetic field has a stabilizing effect on the instability. Without the effects of magnetic field, Joule heating and viscous dissipation, the present thermal instability problem reduces to that studied in [6]. For given values of Pr , Pe , Br and Ha , one is interested in determining the minimum critical Rayleigh number and the corresponding wave number for the onset of instability as stationary longitudinal vortices through the solution of equations (37) to (41).

7.3 Numerical Solution

In view of the expressions for the basic velocity and temperature profiles, an analytical solution of the characteristic value problem is apparently not practical. A finite-difference method using an iterative technique is used for the simultaneous solution of the disturbance equations [6]. Using the higher order finite-difference scheme due to Thomas [18], equation (37) and its boundary conditions may be transformed into a quidiagonal system of matrix for a set of algebraic equations and two tridiagonal systems result from equations (38) and (39) and their boundary conditions. Noting that for given values of Pr , Pe , Br and Ha , the basic profiles ϕ_u and ϕ_θ are known, the solution of a

coupled set of equations (37) to (41) can be carried out by using an iterative procedure consisting of the following main steps:

1. At a given axial position x , a value of the wave number a is selected and an eigenvalue Ra is assumed. The disturbance velocity w_k^* is taken as $w_k^* = 2(1 - k/M)$, $k = 2, 3, \dots, M$ to conform to the primary mode of disturbance.

2. The finite-difference solution of equation (38) then yields u_k^* .

3. After knowing w_k^* and u_k^* , equation (39) is solved to obtain ϕ_k^* .

4. Since the right-hand side of equation (37) is now known, new value for w_k^* can be found.

5. An improved eigenvalue $(Ra)_{new}$ can be computed by using the following equation [19]:

$$(Ra)_{new} = (Ra)_{old} \left[\sum_k (w_k^*)_{old}^2 \right]^{1/2} / \left[\sum_k (w_k^*)_{new}^2 \right]^{1/2} \quad (42)$$

The magnitude of the quantity w_k^* is readjusted by the following equation in order to return to the original order of magnitude for computation.

$$w_k^* = (w_k^*)_{new} (Ra)_{new} / (Ra)_{old} \quad (43)$$

6. The steps (2) to (4) are repeated until the following prescribed convergence criterion is satisfied.

$$\epsilon = \frac{1}{k} |(w_k^*)_{\text{new}} - (w_k^*)_{\text{old}}| / \frac{1}{k} (w_k^*)_{\text{new}} \cdot 10^{-6} \quad (44)$$

It is found that only a few iterations are required to satisfy the above condition and five significant figures are found to be correct for critical Ra.

7.4 Results and Discussion

Before presenting the numerical results, it is well to note that the basic fully-developed velocity profile u depends on Ha only and the basic temperature profile ϕ_0 is a function of the parameters Pe, Br and Ha and is independent of Pr. The typical profiles for ϕ_0 are shown in Chapter VI. In the perturbation equations (37) to (39), only two prescribed parameters Pr and Ha appear. The numerical results will be presented in such a way to illustrate the effects of the aforementioned physical parameters on thermal instability.

The effects of the Hartmann number on disturbance profiles w^* , ψ^* and u^* are shown in Figs. 1 and 2, respectively, for fully developed condition ($\bar{x} = 10$) with Pr = 0.7, Pe = 10 and Br = 0, -1. From the normal modes of the disturbances and the definition of the stream function $v = \partial r / \partial z$, $w = -\partial \psi / \partial y$, one obtains $\psi = (iw^+ / a) e^{iay}$ and one may compute the stream function ψ by noting that physical meaning is attached only to the real part. The results are shown in Fig. 3. In Figs. 1, 2 and 3, the magnitude of the maximum disturbance quantity is taken to be one. The neutral

stability curves for $Pe = 10$, $Pr = 0.01$ and 0.7 are shown in Figs. 4 and 5, respectively, where one may see the effects of Hartmann and Brinkman numbers clearly.

The effect of Peclet number on critical Rayleigh numbers Ra^* along the axial coordinate \bar{x} is shown in Figs. 6 to 9 with $Pr = 0.01, 0.7$ and $Br = 0, -1$ for $Ha = 0, 2, 6$ and 10 . In Fig. 6 ($Ha = 0$) with $Pr = 0.7$, the critical Ra^* is seen to decrease monotonically with \bar{x} until an asymptotic value is approached. On the other hand, with $Pr = 0.01$ and $Br = -1$, a local maximum value for Ra^* exists at a certain axial location before reaching the asymptotic value. Furthermore, the region near the thermal entrance ($\bar{x} = 0$) is seen to be more unstable than the region near the fully developed region ($\bar{x} \geq 10$) for $Pr = 0.01$. It is found that the curve for $Pe = 100$ can be regarded as $Pe = \infty$ practically. The merging of the two curves for $Pe = 10$ and 100 at some axial position signifies the disappearance of the axial conduction effect. With $Ha = Br = 0$, the asymptotic value of $Ra^* = 213.47$ which is independent of Prandtl number agrees with the well-known value of $1708/8$ for the Benard problem. This can be explained from the perturbation equations. For fully developed flow, $\partial \theta_0 / \partial x = 0$ in equation (39) and with $Ha = Br = 0$, equations (37) and (39) become identical with those of the Benard problem.

It is difficult to explain the reasons for the occurrence of the local maximum for Ra^* in the thermal entrance region as noted earlier. Considering the case with $Ha = 0$,

it appears that the cause for the phenomenon is due to the combined effect of the convective term $(u^*/Pr)\partial\phi_0/\partial x$ and the term involving Br on the right-hand side of the perturbation equation (39). Noting that the basic profiles $u_0(z)$ and $\theta_0(x,z)$ are independent of Pr, one may conclude that the relative magnitude of Pr and Br also plays some role leading to the occurrence of the phenomenon. Figs. 7 to 9 reveal that as the value of Ha increases, the phenomenon becomes less appreciable. The effect of the Hartmann number on the asymptotic value of Ra^* is of interest since for the fully developed flow, one has $\partial\phi_0/\partial x = 0$ and the perturbation equations (37) and (39) become identical with those of Chandrasekhar [9] when $Br = 0$. It is found that the present asymptotic results with $Br = 0$ agree with those of [9]. From Fig. 6 to 9, it is seen that with the increase of Hartmann number, the effect of Brinkman number on the asymptotic value of Ra^* becomes less appreciable. Figs. 10 to 13 show clearly the effects of Ha and Pr on the distribution of Ra^* along the axial direction \bar{x} for given values of Pe and Br. The present investigation shows that magnetic field has a stabilizing effect and the decreasing Prandtl number has a destabilizing effect in the thermal entrance region. The effects of Ha and Br on the distribution of Ra^* along \bar{x} are shown in Figs. 14 to 17 for given values of Pe and Pr. For reference, the distributions of the wave numbers a^* corresponding to Fig. 14 and 15 are shown in Fig. 18 and 18, respectively.

7.5 Concluding Remarks

1. The analysis [9] on thermal instability of a horizontal fluid layer confined between two rigid plates subjected to a vertical uniform magnetic field is extended to the case with main flow (Hartmann flow). The present analysis includes the axial conduction, viscous dissipation and Joule heating effects.

2. The numerical results are obtained for $Pr = 0.7$ (air), 0.01 (liquid metal), $Pe = 10, 100, \dots$, $Br = 0, -1$, and $Ha = 0, 2, 6, 10$ with $K = 1$ and $\theta_0 = 1$ only. The case with $K = 1$ signifies the open circuit condition and $\theta_0 = 1$ means $T_0 = T_2$ (entrance temperature is equal to upper plate temperature). At $Br = -1$, the viscous dissipation effect may be considered to be appreciable. It is found that the axial conduction and the magnetic field have a stabilizing effect and the effect of Brinkman number appears to be dependent upon other parameters such as Ha and Pe . It is observed that the combined effect of Prandtl and Brinkman numbers in the perturbation equation (39) may lead to a locally stabilizing effect in some region of the channel before the fully-developed region.

3. For high Prandtl number fluid, the flow is more stable in the thermal entrance region than in the fully-developed region, but the opposite is true for small Prandtl number fluid. However, the Brinkman number has a destabilizing effect in the fully-developed region. When Pr is small, the critical Rayleigh number does not change appreci-

ably throughout the whole entrance length at say $Ha = .10$.

4. The accuracy and convergence of the numerical solution are checked by comparing the present numerical results with those reported in the literature for the limiting cases [6,9].

5. The present instability results are useful in predicting the onset of longitudinal vortex rolls in wide horizontal rectangular channels and the complete numerical results for Ra^* and a^* are listed in table 1 to 3.

6. As noted in Chapter VI, for low Peclet number flow regime with viscous dissipation effects, the entrance condition of uniform fluid temperature at $\bar{x} = 0$ must be regarded as an approximate one. Consequently, numerical calculation is not made for $Pe < 10$.

CHAPTER VIII

MAXIMUM DENSITY EFFECTS ON THERMAL INSTABILITY INDUCED BY COMBINED BUOYANCY AND SURFACE TENSION

Nield's linear stability analysis (1964) for a horizontal liquid layer considering surface tension and buoyancy effects is extended to the case of water with maximum density effect for the temperature range 0 - 30°C. Two thermal parameters (λ_1, λ_2) and three physical parameters (Bi, Ra, Ma) appear in the analysis. Typical results are presented for the cases involving heating from below and above.

Nomenclature

A	=	temperature difference ratio, $(T_1 - T_{\max})/\tau d$
a	=	dimensionless wave number
Bi	=	Biot number, $q_0 d/K$
d	=	liquid layer thickness
g	=	gravitational acceleration
K	=	thermal conductivity of liquid
M	=	number of divisions for liquid layer
Ma	=	Marangoni number, $q_0 (\Delta T) d / (\mu \alpha)$
P	=	pressure
p	=	dimensionless perturbation pressure, $P' / (\rho_0 \alpha v / d^2)$
q_0	=	rate of change with temperature of the time rate of heat loss per unit area from free upper surface
Ra	=	Rayleigh number (see equation (10))
T, T_1, T_2	=	temperature, lower plate temperature, free surface temperature, respectively
t	=	time
U, V, W	=	perturbation velocity components in X, Y, Z , directions

u, v, w	= dimensionless perturbation velocities, $(u, v, w)/(c/d)$
X, Y, Z	= rectangular coordinates
x, y, z	= dimensionless coordinates, $(X, Y, Z)/d$
	= thermal diffusivity
	= coefficient of thermal expansion
β_1, β_2	= temperature coefficients for density- temperature relationship
θ	= dimensionless temperature disturbance, $\theta'/\Delta T$
μ	= viscosity
ν_1, ν_2	= thermal parameters defined in equation (9)
	= kinematic viscosity
ρ_0	= density, reference density
σ_0	= negative of the rate of change of sur- face tension with temperature
	= vertical temperature gradient, $(T_1 - T_2)/d$
ΔT	= temperature difference, $(T_1 - T_2) = \Delta T$

Superscripts and Subscripts

prime, perturbation quantity

b

max

- = dimensionless disturbance amplitude
- = quantity at unperturbed static state
- = value at a density maximum

8.1 Introduction

In recent years, experimental investigations on the onset of convection in a horizontal water layer have been reported in the literature for the thermal conditions involving both melting [1-4] and formation [1,5] of ice. In these studies, the water layer is characterized by stable upper region and potentially unstable lower region separated by an interface with maximum density at 4°C and by continuously changing layer thickness. Theoretical studies on thermal instability of a horizontal liquid layer with maximum density have also been presented for various boundary conditions corresponding to rigid and free surfaces [6-10]. Previous theoretical and experimental investigations on thermal instability with maximum density effects are confined to Rayleigh problem only where the driving force for convection is buoyancy force. For thin horizontal liquid layers with an upper free surface, it is known that the onset of convection can be induced by surface-tension gradients [11] and buoyancy forces [12,13].

The purpose of this study is to determine the stability criteria for the onset of cellular convection driven by surface tension and buoyancy force in a horizontal thin liquid layer by considering the density inversion effect for water using a cubic temperature-density relationship. The lower boundary is taken to be rigid and thermally conducting while at the upper free surface Pearson's boundary conditions [11,12] are imposed to facilitate the analysis.

With the maximum density effect, the liquid layer can be unstable regardless of whether heating is from below or above. The physical model in the present instability analysis is patterned after that of Nield [12]. The maximum density effect for water temperatures ranging from 0 to 30°C of primary concern in this study. The temperature regime under consideration may be observed under northern climatic conditions. The results of present analysis may be used in assessing the importance of cellular convection in the growth and decay of ice in contact with a thin water layer. The incorporation of the maximum density effect in instability analysis on buoyancy and surface-tension induced cellular convection does not appear to have been considered in the past.

3.2 Formulation of Thermal Instability Problem

Following the known procedure for linear stability analysis [10,14,15] and referring to the coordinate system shown in Fig. 3, the perturbation equations can be written as

$$\frac{\partial U}{\partial X} + \frac{\partial V}{\partial Y} + \frac{\partial W}{\partial Z} = 0 \quad (1)$$

$$\frac{\partial U}{\partial t} = -\frac{1}{\rho_0} \frac{\partial P'}{\partial X} + \nu \nabla_{X,Y,Z}^2 U \quad (2)$$

$$\frac{\partial V}{\partial t} = -\frac{1}{\rho_0} \frac{\partial P'}{\partial Y} + \nu \nabla_{X,Y,Z}^2 V \quad (3)$$

$$\frac{\partial W}{\partial t} + \frac{1}{\rho_0} \frac{\partial P'}{\partial Z} + \nabla_{X,Y,Z}^2 W = \frac{\partial \rho'}{\partial t} g \quad (4)$$

$$\frac{\partial \theta'}{\partial t} = \alpha \nabla_{X,Y,Z}^2 \theta' \quad (5)$$

where $\nabla_{X,Y,Z}^2 = \partial^2/\partial X^2 + \partial^2/\partial Y^2 + \partial^2/\partial Z^2$ and the perturbed quantities for temperature, pressure and density are defined by $T = T_b(Z) + \theta'(t, X, Y, Z)$, $P = P_b + P'$ and $\rho = \rho_b + \rho'$, respectively. As shown in [12], the boundary conditions at the lower boundary are

$$W = 0, \quad \frac{\partial W}{\partial Z} = 0 \quad \text{and} \quad \theta' = 0 \quad \text{at} \quad Z = 0$$

while at the upper boundary

$$W = 0, \quad \rho_0 \frac{\partial^2 W}{\partial Z^2} = \rho_0 \left(\frac{\partial^2 \theta'}{\partial X^2} + \frac{\partial^2 \theta'}{\partial Y^2} \right) \quad \text{and} \\ -K \frac{\partial \theta'}{\partial Z} = q_0 \theta' \quad \text{at} \quad Z = d \quad (7)$$

The density-temperature relationship for water can be approximated by the following equation for the temperature range 0 to 30°C [10].

$$\rho = \rho_{\max} [1 - \gamma_1 (T - T_{\max})^2 - \gamma_2 (T - T_{\max})^3] \quad (8)$$

Considering the change in the density ρ caused by the temperature perturbation θ' , one obtains the following expression after neglecting the terms containing $(\theta')^2$ or higher order:

$$\rho = \rho_{\max} \left[2\gamma_1 (\Delta T) \left(1 + \frac{3\gamma_2}{2\gamma_1} (\Delta T) \right) \right] \theta' \left[1 + \lambda_1 \left(\frac{z}{d} \right) + \lambda_2 \left(\frac{z}{d} \right)^2 \right] \quad (9)$$

$$\text{where } \lambda_1 = \left(-\frac{1}{A} \right) \frac{1 + 3 \frac{\gamma_2}{\gamma_1} (\Delta T)}{1 + \frac{3\gamma_2}{2\gamma_1} (\Delta T)}, \quad \lambda_2 = \left(\frac{1}{A^2} \right) \frac{\frac{3\gamma_2}{2\gamma_1} (\Delta T)}{1 + \frac{3}{2} \frac{\gamma_2}{\gamma_1} (\Delta T)}$$

$A = (T_1 - T_{\max})/\Delta T$ and $\Delta T = T_1 - T_2 = \tau d$. The thermal parameters λ_1 and λ_2 were first introduced by Sun, Tien and Yen [10].

Introducing the dimensionless variables $(X, Y, Z) = d(x, y, z)$, $(U, V, W) = (\alpha/d) (u, v, w)$, $P' = (\rho_0 \alpha v / d^2) p$, $\theta' = (\Delta T) \theta$, and eliminating u, v by using continuity equation, one obtains the following perturbation equations by assuming the principle of exchange of stability to be valid [10,15].

$$\nabla^2 \nabla^2 w = - Ra (1 + \lambda_1 z + \lambda_2 z^2) \nabla_1^2 \theta \quad (10)$$

$$\nabla^2 \theta = - w \quad (11)$$

where $Ra = q(2\gamma_1 \Delta T)(\Delta T)d^3 / [1 + (3\gamma_2 / 2\gamma_1)(\Delta T)] / (\rho \alpha)$,

$\nabla^2 = \partial^2 / \partial x^2 + \partial^2 / \partial y^2 + \partial^2 / \partial z^2$ and $\nabla_1^2 = \partial^2 / \partial x^2 + \partial^2 / \partial y^2$.

The boundary conditions are

$$w = \frac{\partial w}{\partial z} = 0 \text{ at } z = 0 \quad (12)$$

$$w = 0, \quad \frac{\partial w}{\partial z} = Ma \nabla_1^2 \theta \text{ and } \frac{\partial \theta}{\partial z} = -Bi \theta \text{ at } z = 1 \quad (13)$$

where $Ma = \gamma_2 (\Delta T) d / (\rho \alpha)$ = Marangoni number and $Bi = q_0 d / K$ = Biot number. In contrast to the classical Benard Problem, the onset of convection is possible with heating from below or above because of the presence of $(\Delta T)^2$ in the expression for Rayleigh number. Since restriction is made to the case where instability first appears in the form of cellular convection rather than oscillations associated with over-stability, the following normal modes can be assumed for the disturbance quantities.

$$[w, \theta] = [w^+(z), \theta^+(z)] \exp[i(a_1 x + a_2 y)] \quad (14)$$

Substituting equation (14) into equations (10) and (11), one obtains

$$(D^2 - a^2)^2 w^+ = a^2 Ra (1 + \lambda_1 z + \lambda_2 z^2) \theta^+ \quad (15)$$

$$(D^2 - a^2)\theta^+ = w^+ \quad (16)$$

With the boundary conditions

$$w^+ = Dw^+ = \theta^+ = 0 \text{ at } z = 0 \quad (17)$$

$$w^+ = 0, D^2w^+ = -a^2Ma\theta^+ \text{ and } D\theta^+ = -Bi\theta^+ \text{ at } z = 1 \quad (18)$$

where $D = d/dz$ and $a = (a_1^2 + a_2^2)^{1/2}$ is the wave number of the disturbance. For the limiting case $Ma = 0$ and $Bi = \infty$, the present eigenvalue problem reduces to that discussed by Sun, Lien and [10]. When $Ra = 0$, the problem reduces to that solved by [11]. The limiting values $Bi = 0$ and ∞ correspond to constant heat flux and constant temperature and the surface is usually referred to as "insulating" and "thermally conducting" respectively. For given thermal boundary conditions (given λ_1, λ_2 and Bi) and a given Marangoni number Ma , the neutral stability relations give Ra as a function of a and the critical (minimum) Rayleigh number is sought. Conversely when Ra is known, one can determine the critical Marangoni number and the corresponding wave number. Apparently, the present problem can be solved by analytical method [10,12,15,16] as well as finite-difference method.

The finite-difference scheme used is due to Thomas

[17,18] and the iterative solution starts with equation (11) by using $w_k^+ = \sin(2\pi k/M)$, $k = 2, \dots, M$ for the disturbance velocity w^+ . The mesh size used is $M = 50$ and a new and improved eigenvalue Ra or Ma is calculated by the following equation [19].

$$(Ra, Ma)_{new} = (Ra, Ma)_{old} \left[\frac{\sum_k (w_k^+)_{old}^2}{\sum_k (w_k^+)_{new}^2} \right]^{1/2} \quad (19)$$

The convergence criterion is

$$\left| \frac{\sum_k (w_k^+)_{new} - \sum_k (w_k^+)_{old}}{\sum_k (w_k^+)_{new}} \right| \leq 10^{-6} \quad (20)$$

It is found that only a few iterations are required to satisfy the above criterion and five significant figures for critical eigenvalue are correct.

8.3 Numerical Results and Discussion

Because of the number of parameters involved, only typical numerical results can be presented here. The thermal condition parameters λ_1, λ_2 depend on A as well as $\Delta T = \Delta d$. For the temperature range (0 - 30°C) under consideration, A is always positive and λ_1 is always negative. Furthermore, the temperature coefficient γ_1 (positive) is of order 10^{-5} and λ_2 (negative) is of order 10^{-6} . The expansion for λ_2 reveals that λ_2 is negative for heating from below

26

and positive for heating from above. In addition, the unstable liquid layer is always confined to the region near the bottom plate and instability occurs only when $l_1 > 4^\circ\text{C}$ for heating from below and when $l_1 < 4^\circ\text{C}$ for heating from above.

Figs. 1 and 2 show neutral stability curves for various cases and the effect of the parameter can be seen clearly. The limiting cases of $Ra = 0$ and $Ma = 0$ corresponds to Pearson problem [11] and Rayleigh problem, respectively. The distributions of eigenfunctions w^+ and θ^+ are shown in Fig. 3 for $Ma = 10$, $\lambda_1 = -1.5$, $\lambda_2 = -0.2$ (heating from below) with Biot number as parameter. It is seen that the curves are quite similar in the lower region up to the location z where the value is maximum. Near the upper free surface, the Biot number effect is quite appreciable particularly for $Bi > 10$. The disturbance profiles for $\lambda_1 = -2$, $\lambda_2 = 0.4$ (heating from above) and $Bi = 100$ are shown in Fig. 4. With $Ma = 0$, the disturbance quantity becomes negative. Otherwise the curves for $Ma = -30$ and -1000 are similar.

The relation between critical Marangoni number Ma^* and Rayleigh number is shown in Fig. 5 for a range of Biot numbers with $\lambda_1 = -1.5$ and $\lambda_2 = -0.2$ (heating from below). As Bi increases, the critical Marangoni number also increases supporting the physical explanation given in [12] for the case of conducting free surface ($Bi = \infty$). Fig. 6 illustrates the variation of the critical Rayleigh number Ra^* with the Marangoni number for a range of Biot numbers with

$\lambda_1 = -1.25$ and $\lambda_2 = 0$. The general trend is similar to that shown in Fig. 7 of [13] which corresponds to the limiting case without maximum density effect. For smaller Biot numbers, the Marangoni effect is seen to be appreciable. As explained in [12], the critical Rayleigh number for a fixed value of Ma is clearly seen to be an increasing function of Bi . The expression for the thermal parameter β reveals that $\lambda_2 = 0$ when $\lambda_2 = 0$ (parabolic density-temperature relation valid for temperature range $0 - 8^\circ\text{C}$) or $T_1 = T_{\text{max}}$. For given values of Marangoni number, the relation between critical Rayleigh number Ra^* and Biot number is shown in Fig. 7 for $\lambda_1 = -1.5$ and $\lambda_2 = -0.2$ (heating from below). At $Bi = 10^4$, the asymptotic value $Ra^* = 7023.4$ is reached. In interpreting the behavior of the curves for $Ma = 100$ and 1000 at the other end, it is useful to note that for a given Marangoni number a critical value of Ra^* does not exist below a certain value of Bi as shown in Fig. 6. Similar plot for the case of heating from above with $\lambda_1 = -2.0$ and $\lambda_2 = 0.4$ is shown in Fig. 8. One also notes the existence of the asymptotic value for Ra^* at $Bi = 10^4$. Selected numerical instability results are listed in Tables 1 and 2 for future reference. For the case when buoyancy effects are negligible ($Ra = 0$), the values of the critical Marangoni number and the corresponding wave number agree excellently with those listed in [12,20] for various values of Bi . On the other hand, with $Ma = 0$ and $Bi = 10^4$, the values of $Ra^* = 7023.4$ and $a^* = 2.992$ compare well with

$Ra^* = 7027.86$ and $a^* = 2.987$ listed in [21] for $Bi = 0$.

Thus, one may conclude that the present numerical results are sufficiently accurate (five significant figures are correct).

Nield [12,25] concludes for the case of linear density variation that the coupling between the buoyancy and surface-tension effects is surprisingly tight for all values of Bi and especially tight for $Bi = 0$. It is instructive to compare the present results considering maximum density effects with those shown in Figs. 1 and 2 of [12]. The comparison is shown in Figs. 9 (plot of Marangoni and Rayleigh numbers for marginal stability) and 10 (plot of wave number corresponding to marginal stability against normalized Rayleigh number). Fig. 9 shows that with maximum density effect the coupling is rather weak and the Biot number effect is characteristically different. Furthermore, Nield's result [12] shows that the form of the relationship between Ma and Ra is a rather weak function of the Biot number but this is not so for the present problem. As noted by Nield [12,25], the departure of an actual curve from the straight line, $Ra/Ra_c + Ma/Ma_c = 1$, representing perfect coupling, is a measure of the amount of uncoupling. Ra_c is the critical Rayleigh number corresponding to $Ma = 0$ and Ma_c corresponds to $Ra = 0$. In Fig. 10, one sees that when the free surface is "insulating" ($Bi = 0$), the coupling is especially tight for the case of linear density variation [12] but the dimensionless wave number for the present

problem varies considerably as the value of Ra/Ra_c increases from 0 to 1. Fig. 10 also shows that larger cells or smaller wave numbers are associated with the insulating case $Bi = 0$. At this point, Fig. 3 also supports the observation that with an insulated boundary it is easier for temperature perturbations to be set up [12]. As Bi increases, the corresponding wave number increases and the size of the convection cell decreases.

Streamlines in Benard convection cells induced by surface tension and buoyancy are given by Nield [22]. The streamlines in the two vertical planes of symmetry of a hexagonal cell at the onset of convection are shown in Fig. 11 (a) and (b) for $\lambda_1 = -1.5$, $\lambda_2 = -0.2$, $Ma = 10$ and $Bi = 100$ by using equations (4) and (5) of [22]. In Fig. 11, the left-hand margin represents the cell boundary and the right-hand margin corresponds to the cell centre. In contrast to the streamline patterns shown in [22], the eyes of the streamlines are seen to be located nearer to the lower rigid plate. Fig. 3 also shows that the maximum vertical disturbance w^+ is located nearer to the bottom plate. One notes that for the present problem the unstable layer is situated near the bottom plate.

8.4 Concluding Remarks

1. The physical model [12] assumes that the free upper liquid surface remains undeformed. Nield's linear stability analysis [12] considering surface tension and buoyancy

effects has been confirmed by experiments [23,24]. The limitation of the assumption that departures of the upper surface from a horizontal plane are negligible as well as the possibility for oscillatory instability is well discussed by Nield [25]. Future analysis should include surface viscosity effect and surface deformation pointed out by Scriven and Sternling [26].

2. The case of heating from above may have direct application in surface melting involving ice layer on a lake or pond. The present analysis can be used in predicting the onset of convection for a thin liquid layer on ice driven by surface-tension gradients and buoyancy forces.

3. Within the scope of present study, a full parametric study of the problem is not practical since two thermal condition parameters (λ_1, λ_2) and three flow parameters (Bi, Ra, Ma) appear in the analysis. The graphical results presented are useful in assessing the effects of Bi, Ra and Ma on the onset of instability.

4. The Biot number effect is similar to that discussed in [12]. The detailed physical explanation given in [12] provides further insight into the role of maximum density in the present instability problem.

CHAPTER IX

THERMAL INSTABILITY OF BLASIUS FLOW ALONG HORIZONTAL PLATES

The thermal instability of laminar forced convection flow along a horizontal semi-infinite flat plate heated isothermally from below or cooled isothermally from above is investigated for disturbances in the form of stationary longitudinal vortices which are periodic in the spanwise direction. The analysis uses non-parallel flow model considering the variation of the basic flow and temperature fields with the streamwise coordinate as well as the transverse velocity component in the disturbance equations.

The critical values of the Grashof number $Gr_L^* = Gr_X^* / Re_X^{3/2}$ are obtained for Prandtl numbers ranging from 10^{-2} to 10^4 .

The Prandtl and Reynolds numbers effects on vortex-type instability for Blasius flow along horizontal plates are clarified.

Nomenclature

a	= wave number, $2\pi/\lambda$
D	= $d/d\eta$
F	= $(\eta f' - f)/2$
f	= dimensionless stream function
g	= gravitational acceleration
G	= eigenvalue, Gr_L/Re_L
Gr_L	= Grashof number based on L , $g\beta(\Delta T)L^3/\nu^2$
Gr_X	= Grashof number based on X , $g\beta(\Delta T)X^3/\nu^2$
L	= characteristic length, $(\nu X/U_\infty)^{1/2}$
M	= number of divisions in y direction
P	= Pressure
Pr	= Prandtl number, ν/α
p	= dimensionless pressure, $P'/(\rho U_\infty^2/Re_L)$
Re_L, Re_X	= Reynolds numbers, $(U_\infty L/\nu) = Re_X^{1/2}$ and $(U_\infty X/\nu)$, respectively.
T	= temperature
U, V, W	= velocity components in X, Y, Z directions
u, v, w	= dimensionless perturbation velocities, $(U', V', W')/U_\infty$
$X, Y, Z,$	= rectangular coordinates
$x, y, z,$	= dimensionless coordinates, $(X, Y, Z)/L$

α	= thermal diffusivity
β	= coefficient of thermal expansion
η	= similarity variable, $Y/L = Y(U_\infty/\nu X)^{1/2} = y$
θ	= dimensionless temperature disturbance, $\theta'/\Delta T$
λ	= dimensionless wavelength of vortex rolls, $2\pi/a$
ν	= kinematic viscosity
ρ	= density
τ	= dimensionless temperature, $(T_b - T_\infty)/\Delta T$
ΔT	= temperature difference, $(T_w - T_\infty)$

Subscripts and Superscripts

*	= critical value or dimensionless disturbance amplitude.
'	= prime, disturbance quantity or differentiation with respect to η .
b	= basic flow quantity
w	= value at wall
∞	= free stream condition

9.1 Introduction

Buoyancy effects in laminar forced convective flow over a heated horizontal semi-infinite flat plate were first studied by Mori [1] and Sparrow and Minkowycz [2] independently. These early studies apparently motivated further investigations [3-6] in recent years. When a horizontal laminar boundary layer is heated from below or cooled from above, the layer is potentially unstable because of its top-heavy situation due to the density variation of fluid with temperature. The situation is somewhat analogous to the thermal instability of plane Poiseuille flow [7-10] or the well-known Görtler instability of curved boundary layers [11]. The problem of hydrodynamic stability for the laminar boundary layer involving the solution of Orr-Sommerfeld equation has been studied rather extensively in the past. In contrast, the thermal instability problem does not appear to have been reported in the literature.

The purpose of this study is to determine theoretically the conditions marking the onset of longitudinal vortex rolls in a horizontal Blasius flow where the flat plate is heated isothermally from below or cooled isothermally from above. After the onset of vortex rolls, the flow and temperature fields assume a three-dimensional character and the existing flow and heat transfer results for laminar forced convection over a flat plate may no longer apply. It is then obvious that the present problem is of considerable practical interest.

9.2 The Basic Flow

Consideration is given to a horizontal laminar boundary-layer flow with free stream velocity U_∞ and free stream temperature T_∞ along a flat plate where the wall temperature $T_w (> T_\infty)$ is constant. The laminar forced convection flow problem is governed by the following set of equations [12].

$$f'''' + \frac{1}{2} f f'' = 0 \quad (1)$$

$$\tau'' + \frac{1}{2} \text{Pr} f \tau' = 0 \quad (2)$$

with the boundary conditions

$$f(0) = f'(0) = \tau(\infty) = 0, \quad f'(\infty) = \tau(0) = 1 \quad (3)$$

where the Blasius similarity variable is $\eta = Y(U_\infty/\nu X)^{1/2} = Y/L(X)$ with $L(X) = (\nu X/U_\infty)^{1/2}$, the stream function $\psi = (\nu X U_\infty)^{1/2} f(\eta)$, the normalized temperature $\tau(\eta) = (T_b - T_\infty)/(T_w - T_\infty)$ and $\text{Pr} = \nu/\alpha = \text{Prandtl number}$. Equation (1) is solved by the fourth order Runge-Kutta method and the temperature distribution τ is

$$\tau(\eta) = 1 - \frac{\int_0^{\eta} [\exp(-\frac{Pr}{2} \int_0^{\eta} f d\eta)] d\eta}{\int_0^{\infty} [\exp(-\frac{Pr}{2} \int_0^{\eta} f d\eta)] d\eta} \quad (4)$$

The basic flow is a two-dimensional boundary layer flow which depends on streamwise and transverse directions.

9.3 The Thermal Instability Problem

To study the vortex instability of the basic Blasius flow heated from below (or cooled from above), the perturbation quantities are superimposed on the basic quantities as

$$U = U_b(X, Y) + U'(Y, Z), \quad V = V_b(X, Y) + V'(Y, Z), \quad W = W'(Y, Z)$$

$$T = T_b(X, Y) + \theta'(Y, Z), \quad P = P_b = \rho_{\infty} g Y + P'(Y, Z)$$

As discussed in [13,14], all of the flow disturbance quantities are taken to be a function of Y and Z only for neutral stability involving G6rler vortices. Further details regarding the assumed form of disturbances and some experimental fact are explained clearly in [13]. After applying the linear stability theory and using Boussinesq approximation, the perturbation equations referring to the coordinate system shown in Fig. 1 become

$$\frac{\partial V'}{\partial Y} + \frac{\partial W'}{\partial Z} = 0 \quad (6)$$

$$U' \frac{\partial U_b}{\partial X} + V_b \frac{\partial U'}{\partial Y} + V' \frac{\partial U_b}{\partial Y} = \nu \nabla_1^2 U' \quad (7)$$

$$V_b \frac{\partial V'}{\partial Y} + V' \frac{\partial U_b}{\partial Y} = -\frac{1}{\rho} \frac{\partial P'}{\partial Y} + \nu \nabla_1^2 V' + g\beta\theta' \quad (8)$$

$$V_b \frac{\partial W'}{\partial Y} = -\frac{1}{\rho} \frac{\partial P'}{\partial Z} + \nu \nabla_1^2 W' \quad (9)$$

$$U' \frac{\partial T_b}{\partial X} + V' \frac{\partial T_b}{\partial Y} + V_b \frac{\partial \theta'}{\partial Y} = \alpha \nabla_1^2 \theta' \quad (10)$$

where $\nabla_1^2 = \partial^2/\partial Y^2 + \partial^2/\partial Z^2$ and the terms involving V_b , $\partial U_b/\partial X$ and $\partial T_b/\partial X$ are retained. The term $U' \partial V_b/\partial X$ is neglected following the boundary layer approximation $\partial V_b/\partial X \approx 0$. The non-parallelism of the basic flow is found to be important in recent investigations [13,14] dealing with the vortex instability of natural convection flow on inclined isothermal plates. The basic flow and temperature quantities can be written in the following form

$$U_b = U_\infty f'(\eta), \quad V_b = (U_\infty/2Re_L)(\eta f' - f) = (U_\infty/Re_L)F, \quad (11)$$

$$T_b = T_\infty + \Delta T \tau(\eta)$$

where $Re_L = U_\infty L/\nu = (U_\infty X/\nu)^{1/2} = Re_X^{1/2}$, $F = (\eta f' - f)/2$
and $\Delta T = T_w - T_\infty$.

After introducing the following dimensionless variables, $(x, y = \eta, z) = (X, Y, Z)/L(X)$, $(u, v, w) = (U', V', W')/U_\infty$,
 $p = P'/(ρU_\infty^2/Re_L)$, $\theta = \theta'/\Delta T$ the disturbance equations can
be recast into the dimensionless form as

$$\frac{\partial v}{\partial y} + \frac{\partial w}{\partial x} = 0 \quad (12)$$

$$F \frac{\partial u}{\partial y} - \frac{1}{2} \eta f'' u + Re_L f'' v = \nabla^2 u \quad (13)$$

$$F \frac{\partial v}{\partial y} + \frac{1}{2} \eta f'' v = \nabla^2 v - \frac{\partial p}{\partial y} + G\theta \quad (14)$$

$$F \frac{\partial w}{\partial y} = \nabla^2 w - \frac{\partial p}{\partial z} \quad (15)$$

$$F \frac{\partial \theta}{\partial y} - \frac{1}{2} \eta \tau' u + Re_L \tau' v = \frac{1}{Pr} \nabla^2 \theta \quad (16)$$

where $G = g\beta(\Delta T)LRe_L/U_\infty^2 = Gr_L/Re_L$, $Gr_L = g\beta(\Delta T)L^3/\nu^2 =$
 $Gr_X/Re_X^{3/2}$, $Gr_X = g\beta(\Delta T)X^3/\nu^2$ and $\nabla^2 = \partial^2/\partial y^2 + \partial^2/\partial z^2$. Upon
eliminating the dependent variable w and the pressure terms
from equations (14) and (15) using continuity equation (12),
one obtains

$$\nabla^2 u = F \frac{\partial u}{\partial y} + \frac{1}{2} \eta f'' u = \text{Re}_L f'' v \quad (17)$$

$$\nabla^2 \nabla^2 v = F \frac{\partial}{\partial y} \nabla^2 v - \frac{1}{2} \eta f'' \nabla^2 v = -G \frac{\partial^2 \theta}{\partial z^2} \quad (18)$$

$$\nabla^2 \theta = \text{Pr} F \frac{\partial \theta}{\partial y} = \text{Pr} \tau' (\text{Re}_L v - \frac{1}{2} \eta u) \quad (19)$$

The boundary conditions are $u = v = v' = \theta = 0$ at $y = 0$ and ∞ . For the stationary longitudinal vortices which are periodic in the spanwise direction and neglecting the x -dependences [13,14] at the neutral stability, the following disturbance forms are applicable.

$$u = u^+(y) \exp(iaz), \quad v = v^+(y) \exp(iaz), \quad \theta = \theta^+(y) \exp(iaz) \quad (20)$$

The quantity a is the wave number of the disturbance.

Substituting equation (20) into the perturbation equations (17) to (19), the following set of equations results.

$$[(D^2 - a^2) - FD + \frac{1}{2} \eta f''] u^+ = \text{Re}_L f'' v^+ \quad (21)$$

$$[(D^2 - a^2)^2 - F(D^3 - a^2 D) - \frac{1}{2} \eta f'' (D^2 - a^2)] v^+ = a^2 G \theta^+ \quad (22)$$

$$[(D^2 - a^2) - \text{Pr}FD]\theta^+ = \text{Pr} \tau' (\text{Re}_L v^+ - \frac{1}{2} \eta u^+) \quad (23)$$

where $D = d/dy$. By setting $u^+ = u^*$, $\text{Re}_L v^+ = v^*$, $\theta^+ = \theta^*$ and $G\text{Re}_L = Gr_L$, the parameter Re_L does not appear explicitly and the resulting system of equations becomes

$$[(D^2 - a^2) - FD + \frac{1}{2} \eta f'']u^* = f''v^* \quad (24)$$

$$[(D^2 - a^2)^2 - F(D^3 - a^2D) - \frac{1}{2} \eta f''(D^2 - a^2)]v^* = a^2 Gr_L \theta^* \quad (25)$$

$$[(D^2 - a^2) - \text{Pr}FD]\theta^* = \text{Pr} \tau' (v^* - \frac{1}{2} \eta u^*) \quad (26)$$

The boundary conditions are

$$u^* = v^* = Dv^* = \theta^* = 0 \text{ and } \eta = 0 \text{ and } \infty \quad (27)$$

For the conventional parallel flow assumption for the basic flow, the terms involving F as well as the x -derivatives of the basic quantities are neglected. In the disturbance equations, the terms on the right-hand side may be regarded as the driving terms. Equations (24) to (27) form an eigenvalue problem and the solution will be effected by a numerical method.

9.4 Method of Solution

The fourth-order finite-difference scheme used in this study is due to Thomas [15] in his study on the stability of plane Poiseuille flow and the detailed derivations are given by Chen [16] in a study on the hydrodynamic stability of developing flow in a parallel-plate channel. In the present finite-difference solution, a finite value of η must be prescribed to satisfy the boundary condition at $\eta = \infty$ [17]. For this purpose, two cases are considered depending on the value of Prandtl number. When $Pr \geq 1$, the condition at infinity for θ^* is replaced by $\theta^* = 0$ at $\eta = \eta_1$ corresponding to $\tau \leq 10^{-8}$ since as $\tau \rightarrow 0$ one has $\tau' \rightarrow 0$. Equation (26) reveals that the flow field is stable for the region $\eta = \eta_1 \sim \infty$. On the other hand, when $Pr < 1$, the boundary condition $u^* = 0$ is set at $\eta = \eta_2$ corresponding to $(f' - 1) \leq 10^{-8}$ and the conditions $v^* = \theta^* = 0$ are set at $\eta = \eta_1 (> \eta_2)$ corresponding to $\tau \leq 10^{-8}$. As $f' \rightarrow 1$, one has $f'' \rightarrow 0$ and equation (24) shows that $u^* = 0$ for the region $\eta = \eta_1 \sim \infty$. Noting that with $Pr < 1$ the thickness of the thermal boundary layer is larger than that of the hydrodynamic boundary layer, one obtains $v^* = \theta^* = 0$ for the region $\eta = \eta_1 \sim \infty$ from equations (25) and (26). The satisfactory values for the step size Δy , the number of divisions M and the end position η_1 for various Prandtl numbers are found by numerical experiments and the results are listed in Table 1 with η_2 fixed at $\eta_2 = 10.4$.

The finite-difference technique transforms equation

(25) and its boundary conditions into a quidiagonal system of matrix for a set of algebraic equations and similarly two diagonal systems result from equations (24) and (26) and their boundary conditions. The numerical solutions of the quidiagonal and tridiagonal systems are reported in [18] and [19], respectively, and will not be elaborated here.

The iterative procedure for the simultaneous solution of the three perturbation equations consists of the following main steps:

1. With the basic velocity and temperature given, a value of the wave number is selected for a particular Prandtl number.

2. The initial values for the eigenvalue Gr_L and the disturbance velocity v_k^* in the vertical direction are assigned. The selection of the initial value for v_k^* should correspond to the primary mode of disturbance. In this study, $v_k^* = 2(1 - k/M)$, $k = 2, 3, \dots, M$ is used. However, one may note that the initial disturbance in the form of $v_k^* = \sin[(k - 1)\pi/M]$, $k = 1, 2, \dots, M+1$, also leads to a satisfactory result. Any arbitrary form of the disturbance profile satisfying the boundary conditions may be used but the profiles mentioned above are found to yield a faster convergence.

3. The finite-difference form of equation (24) is solved to obtain u_k^* .

4. With v_k^* and u_k^* known, the finite-difference form

of equation (26) is solved to obtain θ_k^* .

5. The right-hand side of equation (25) is now known, and new values of v_k^* are obtained by the finite-difference solution of equation (25).

6. A new and improved eigenvalue can now be computed by the following equation [20].

$$(Gr_L)_{new} = (Gr_L)_{old} \frac{\left| \sum_k (v_k^*)_{old}^2 \right|^{1/2}}{\left| \sum_k (v_k^*)_{new}^2 \right|^{1/2}} \quad (27)$$

The magnitude of the quantity v_k^* is readjusted by the following equation in order to return to the original order of magnitude.

$$v_k^* = (v_k^*)_{new} (Gr_L)_{new} / (Gr_L)_{old} \quad (28)$$

It is well to note that the absolute value for v_k^* cannot be determined from the linearized theory and the correct profile satisfying the governing equation is sought.

7. The steps (3) to (6) are repeated until the following convergence criteria are satisfied.

$$\epsilon_1 = \sum_k |(v_k^*)_{new} - (v_k^*)_{old}| / \sum_k (v_k^*)_{new} \leq 10^{-6} \quad (29)$$

$$\epsilon_2 = |(Gr_L)_{new} - (Gr_L)_{old}| / (Gr_L)_{new} \leq 10^{-8} \quad (30)$$

Numerical experiments show that only a few iterations are required to satisfy the above conditions.

By varying the wave number a and carrying out the above iterative procedure, a minimum eigenvalue Gr_L^* , which permits a solution of the set of the disturbance equations, can be found. The minimum eigenvalue and the corresponding wave number are the critical values which correspond to the onset of instability.

9.5 The Neutral Stability Results and Discussion

9.5.1 Perturbed Velocity and Temperature Fields

Although the primary objective of this investigation is to obtain the critical value of the eigenvalue for the onset of stationary longitudinal rolls which are periodic in the spanwise direction, a study of the perturbed velocity and temperature fields may provide some insight into the physical mechanism of thermal instability. Figs. 1 and 2 show the distributions of the basic profiles for f' , F and τ with the disturbance amplitudes u^* , v^* and θ^* superimposed for the cases of $Pr = 0.7$ and $Pr = 10$ respectively. Since the magnitudes of the disturbance quantities cannot be determined by using the linear stability theory, the magnitude of the maximum disturbance quantity is taken to be 0.1 in the plotting. In order to study the decay of the disturbance

quantity in the vertical direction, the distributions of the disturbances are also shown in Fig. 3 for $Pr = 0.7$ and 10 where the largest magnitude of the disturbances u^* , v^* and θ^* is again taken to be 0.1 . It is noted that the horizontal disturbance velocity u^* is negative suggesting that the secondary flow also derives its energy from the main flow through mutual interactions as represented by the second and third terms on the left-hand side of equation (25). The profiles for u^* and θ^* are seen to be qualitatively similar.

The secondary flow pattern at the onset of instability is of considerable interest. For this purpose one may define a stream function ψ with $v = \partial\psi/\partial z$ and $w = -\partial\psi/\partial y$ satisfying the continuity equation $\partial v/\partial y + \partial w/\partial z = 0$. From the normal modes of the disturbances, one has $v = v^+(y)e^{iaz}$ and $\psi = \psi^+(y)e^{iaz}$. Using $v = \partial\psi/\partial z$ and $v^* = \text{Re}_L v^*$, one obtains $\psi = -[iv^+(y)/a]e^{iaz}$. The physical meaning is attached only to the real part of the stream function and the contour lines are shown in Figs. 4 and 5 for $Pr = 0.7$ and 10 , respectively. It is noted that the dimensionless wavelength is $\lambda = 2\pi/a$ and ψ_{\max} is taken to be one. One immediately notices the striking resemblance between the streamline pattern of vortex disturbance for flow over concave wall [11] and the present secondary streamline pattern caused by buoyancy forces as illustrated in Figs. 4 and 5.

9.5.2 The Neutral Stability Results

The neutral stability curves for Prandtl numbers 0.7 and 10 are presented in Fig. 6 where the eigenvalue Gr_L is plotted against the wave number a . The numerical results for the critical (minimum) values of the Grashof number Gr_L^* and the corresponding wave number a^* are listed in Table 2 for various Prandtl numbers for future reference and the effect of Prandtl number on the critical Grashof number Gr_L^* is shown in Fig. 7.

Taking cognizance of the relationship $Gr_L \doteq Gr_X / Re_X^{3/2}$, the effect of Reynolds number on the critical Grashof number Gr_X^* can be studied readily and the results are presented in Fig. 8 using logarithmic coordinates. It is of particular interest to compare the present result with Sparrow and Minkowycz's result [2] for five percent increase in local heat transfer rate due to buoyancy effect based on pure forced convection flow. For this purpose, the curves on Fig. 1 of [2] are also plotted in Fig. 8. To study the implication of the present result, consider the case of Prandtl number 10. The intersection of the two curves for $Pr = 10$ indicates that at $Re_X = 4.8 \times 10^2$, the longitudinal vortices may set in at $Gr_X = 7.9 \times 10^5$. The present results clearly suggest the possible upper limit of the applicability of the published results [1-6]. Fig. 8 also shows that for the lower Reynolds number flow, the critical Grashof number Gr_X^* is lower for a given Prandtl number.

9.6 Concluding Remarks

1. The thermal instability of the horizontal Blasius flow heated from below or cooled from above is studied by using linear stability theory based on non-parallel flow model whereby the variations of the basic flow quantities, U_b and T_b , with X as well as the transverse velocity component V_b are retained in the perturbation equations. Some similarity exists between the present problem and the Görtler problem.

2. The result shown in Fig. 7 reveals that the minimum critical value of Gr_L^* is lower for higher Prandtl number. The Prandtl number effect can be explained from the definition of Gr_L . For the pure laminar forced convection problem ~~the ratio of the thermal boundary-layer thickness over the~~ velocity boundary-layer thickness is known to be $\delta_T/\delta = Pr^{-1/3}$ approximately with $\delta = 5.83(\nu X/U_\infty)^{1/2} = 5.83 L$. Noting the above expression and considering the same $T = T_w - T_\infty$ and Re_x for two different Prandtl numbers, the ratio of the critical Grashof number Gr_L^* can be readily shown to be $(Gr_L^*)_1/(Gr_L^*)_2 = (g\beta/\nu^2)_1/(g\beta/\nu^2)_2$. For example, with $(Pr)_1 = 0.73$ and $(Pr)_2 = 1170$, one finds the ratio $(Gr_L^*)_1/(Gr_L^*)_2 = (4.2 \times 10^6)/(1.17 \times 10^4)$ and the order of magnitude checks with the results from the present analysis. It is also noted that the temperature gradient $(\Delta T/\delta_T)$ for large Prandtl number fluid is much larger than that of small Prandtl number fluid. In other words, the unstable region for large Prandtl number fluid is confined to a small region inside

the velocity boundary layer. On the other hand, for small Prandtl number fluid, the unstable region extends over a region outside the velocity boundary layer.

3. The basic flow solution for pure forced convection used in this analysis is not valid when Re_x is small (say $< 0[10^2]$). For small Re_x , the terms $\partial^2 U_b / \partial x^2$ and $\partial^2 T_b / \partial x^2$ must be included. When $Re_x = 0$, the eigenvalue problem does not exist and a free convection on a heated horizontal semi-finite flat plate arises. On the other hand, the approximate limit of boundary layer theory is $Re_x < 5 \times 10^5$. In interpreting the present results, it must be pointed out that buoyancy effects are considered only in the perturbation equations. An exact analysis would have to consider ~~combined free and forced convection for basic flow.~~ This together with the variable property effect remains to be investigated in future.

4. The experimental data do not appear to be available for comparison with the present results. It remains for future experiments to obtain the vortex instability data.

CHAPTER X

MAXIMUM DENSITY EFFECTS ON THERMAL INSTABILITY OF HORIZONTAL LAMINAR BOUNDARY LAYERS

Linear stability theory is used to investigate the onset of longitudinal vortices in laminar boundary layers along horizontal semi-infinite flat plates heated or cooled isothermally from below by considering the density inversion effect for water using a cubic temperature-density relationship. The analysis employs non-parallel flow model incorporating the variation of the basic flow and temperature fields with the streamwise coordinate as well as the transverse velocity component in the disturbance equations. Numerical results for the critical Grashof number $Gr_L^* = Gr_X^*/Re_X^{3/2}$ are presented for thermal conditions corresponding to $-0.5 \leq \lambda_1 \leq -2.0$ and $-0.8 \leq \lambda_2 \leq 1.2$.

Nomenclature

a	=	wave number, $2\pi/\lambda$
D	=	operator, d/dn
F	=	$(\eta f' - f)/2$
f	=	dimensionless stream function
g	=	gravitational acceleration
G	=	eigenvalue, Gr_L/Re_L
Gr_L	=	Grashof number based on L
Gr_X	=	Grashof number based on X
L	=	characteristic length, $(\nu X/U_\infty)^{1/2}$
M	=	number of divisions in y direction
P	=	pressure
Pr	=	Prandtl number, ν/α
P	=	dimensionless pressure, $P'/(\rho U_\infty^2/Re_L)$
Re_L, Re_X	=	Reynolds numbers, $(U_\infty L/\nu) = Re_X^{1/2}$ and $(U_\infty X/\nu)$, respectively
T	=	temperature
U, V, W	=	velocity components in X, Y, Z , directions
u, v, w	=	dimensionless perturbation velocities, $(U', V', W')/U_\infty$
X, Y, Z	=	rectangular coordinates

x, y, z	=	dimensionless coordinates, $(X, Y, Z)/L$
α	=	thermal diffusivity
β	=	coefficient of thermal expansion
γ_1, γ_2	=	temperature coefficients for density-temperature relationship
η	=	similarity variable, $Y/L = y$
θ	=	dimensionless temperature disturbance, $\theta'/\Delta T$
λ	=	dimensionless wavelength of vortex rolls, $2\pi/a$
λ_1, λ_2	=	thermal parameters defined by equation (12)
ν	=	kinematic viscosity
ρ	=	density
τ	=	dimensionless basic temperature, $(T_b - T_\infty)/\Delta T$
ϵ	=	$\tau - 1$
ΔT	=	temperature difference, $(T_w - T_\infty)$

Superscripts and Subscripts

*	=	critical value or dimensionless disturbance amplitude
'	=	prime, disturbance quantity or differentiation with respect to η

b = basic flow quantity
max = value at a density maximum
w = value at wall
 ∞ = free stream condition

10.1 Introduction

Thermal instability problems involving a horizontal layer of water with maximum density effect have been studied by various investigators [1-6] in recent years. Experimental investigations utilizing a melting [7-10] or freezing [11] horizontal ice layer were also reported recently. The maximum density effect is known to be important for free convection phenomenon in water exposed to near freezing temperatures. A literature survey shows that the published thermal instability results with maximum density effect are mainly concerned with the initially stationary liquid layer. On the other hand, one notes that little attention has been focussed so far to the related thermal instability problems with main flow.

When a body of water with temperatures ranging from 0°C to say 30°C flows in a horizontal direction, there exists a possibility for the onset of secondary motion regardless of whether the liquid layer is heated (or cooled) from below or above. This is obvious since part of the flowing liquid layer is potentially unstable with density inversion due to a top-heavy situation. The temperature regime mentioned may be found in natural phenomena such as flowing water near the ice cover in northern rivers or lakes.

The physical model chosen for study here is a Blasius flow (laminar boundary-layer flow) along a horizontal flat semi-infinite plate with a constant wall temperature T_w . The free stream temperature is T_{∞} and the liquid possesses

a maximum density over the temperature range between T_w and T_∞ . The purpose of this study is to determine the conditions marking the onset of stationary longitudinal vortices in a horizontal laminar boundary-layer, with maximum density effect. After the onset of longitudinal vortex rolls, the flow resumes a three-dimensional character and the conventional heat transfer results based on steady two-dimensional flow model may no longer apply. The results of present investigation may also provide some insight into the growth and decay of ice layer in contact with flowing water under certain conditions.

10.2 Formulation of the Thermal Instability Problem

The basic flow solutions for velocity and temperature in the steady laminar boundary-layer flow past a horizontal flat plate are well known [12]. Referring to the coordinate system shown in Fig. 1 and introducing the following variables, $\psi = (\nu X U_\infty)^{1/2} f(\eta)$, $\eta = Y(U_\infty/\nu X)^{1/2} = Y/L$, $(\nu X/U_\infty)^{1/2}$ and $\tau(\eta) = (T_b - T_\infty)/(T_w - T_\infty)$, the governing equations and the boundary conditions become [12]

$$f''' + \frac{1}{2} f f'' = 0, \quad \tau'' + \frac{1}{2} Pr f \tau' = 0 \quad (1)$$

$$f(0) = f'(0) = \tau(\infty) = 0, \quad f'(\infty) = \tau(0) = 1 \quad (2)$$

The Blasius problem is solved by the fourth order Runge-Kutta method and the temperature distribution becomes

$$\tau(\eta) = 1 - \frac{\int_0^\eta [\exp(-\frac{Pr}{2} \int_0^\eta f d\eta)] d\eta}{\int_0^\infty [\exp(-\frac{Pr}{2} \int_0^\eta f d\eta)] d\eta} \quad (3)$$

As the temperature difference $|T_{w_0} - T_\infty|$ increases, the vortex rolls will appear eventually in the laminar boundary layer. To study the vortex-type instability of the Blasius flow with a maximum density value at T_{max} between T_w and T_∞ , the perturbation quantities are superimposed on the basic quantities as

$$U = U_b(X, Y) + U'(Y, Z), \quad V = V_b(X, Y) + V'(Y, Z), \quad W = W'(Y, Z) \quad (4)$$

$$T = T_b(X, Y) + \theta'(Y, Z), \quad P = P_b - \rho_\infty g Y + P'(Y, Z)$$

The assumed disturbance forms for the longitudinal vortices which are periodic in the spanwise direction are similar to those given in [13]. Specifically, the secondary flow vortices (Görtler vortices) are assumed to be unchanging with time and non-oscillatory in the streamwise direction. The amplified disturbances are assumed to grow in the main

flow direction but since the neutral stability is of interest here, the first derivatives of all disturbance quantities with respect to X are zero. Furthermore, the second-order derivatives $\partial^2/\partial X^2$ of the disturbances are neglected in conformity with the boundary layer approximation [13,14]. Based on the foregoing discussion, the disturbance quantities are taken to be a function of Y and Z only.

Applying the linear stability theory and using the Boussinesq approximation, the governing equations for the disturbed flow can be written as

$$\frac{\partial V'}{\partial Y} + \frac{\partial W'}{\partial Z} = 0 \quad (5)$$

$$U' \frac{\partial U'_b}{\partial X} + V'_b \frac{\partial U'_b}{\partial Y} + V' \frac{\partial U'_b}{\partial Y} = \nu \nabla_1^2 U'_b \quad (6)$$

$$V'_b \frac{\partial V'_b}{\partial Y} + V' \frac{\partial V'_b}{\partial Y} = -\frac{1}{\rho} \frac{\partial P'_b}{\partial Y} + \nu \nabla_1^2 V'_b + \frac{\delta \rho}{\rho} g \quad (7)$$

$$V'_b \frac{\partial W'_b}{\partial Y} = -\frac{1}{\rho} \frac{\partial P'_b}{\partial Z} + \nu \nabla_1^2 W'_b \quad (8)$$

$$U' \frac{\partial T'_b}{\partial X} + V'_b \frac{\partial T'_b}{\partial Y} + V' \frac{\partial T'_b}{\partial Y} = \alpha \nabla_1^2 T'_b \quad (9)$$

where $v_1^2 = \partial^2/\partial Y^2 + \partial^2/\partial Z^2$. It is noted that non-parallel flow model is employed by retaining the terms involving V_b , $\partial U_b/\partial X$ and $\partial T_b/\partial X$. The term $U \partial V_b/\partial X$ is neglected since $\partial V_b/\partial X = 0$ according to the boundary layer approximation. Recent investigations [13,14] on vortex instability of natural convection flow on inclined surfaces show that the conventional parallel flow assumption is inapplicable for the prediction of the onset of steady longitudinal vortices in boundary layer flow.

The density inversion effect is of primary interest here and the equation of state for water can be approximated by the following equation for the temperature range 0 to 30°C [5].

$$\rho - \rho_{\max} = -\rho_{\max} [\gamma_1 (T - T_{\max})^2 + \gamma_2 (T - T_{\max})^3] \quad (10)$$

For the perturbed flow, the temperature difference $(T - T_{\max})$ becomes

$$\begin{aligned} T - T_{\max} &= T_b + \theta' - T_{\max} = (T_b - T_w) + (T_w - T_{\max}) \\ &+ \theta' = (\Delta T)(\phi + A + \theta) \end{aligned} \quad (11)$$

where $\phi = (T_b - T_w)/\Delta T = \tau - 1$, $A = (T_w - T_{\max})/(T_w - T_{\infty})$,

$\theta = \theta' / \Delta T$ and $\Delta T = T_w - T_\infty$. Considering the change in the density $\delta\rho$ caused by the perturbation θ' in the temperature, one obtains the following expression for $-\delta\rho/\rho$ after neglecting the terms involving θ^2 and θ^3 .

$$-\frac{\delta\rho}{\rho} = 2\gamma_1(A\Delta T)\theta(\Delta T)\left[1 + \frac{3}{2}\frac{\gamma_2}{\gamma_1}(A\Delta T)\right](1 - \lambda_1\phi + \lambda_2\phi^2) \quad (12)$$

$$\text{where } \lambda_1 = \left(-\frac{1}{A}\right) \left[\frac{1 + 3\frac{\gamma_2}{\gamma_1}A\Delta T}{1 + \frac{3}{2}\frac{\gamma_2}{\gamma_1}A\Delta T} \right] \text{ and } \lambda_2 = \left(\frac{1}{A^2}\right) \left[\frac{\frac{3}{2}\frac{\gamma_2}{\gamma_1}A\Delta T}{1 + \frac{3}{2}\frac{\gamma_2}{\gamma_1}A\Delta T} \right]$$

The thermal parameters λ_1 and λ_2 were first introduced by Sun, Tien and Yen [5]. The temperature coefficient γ_1 (positive) is of order 10^{-5} and γ_2 (negative) is of order 10^{-7} . It is noted that A is always positive and λ_1 is always negative for the temperature range (0-30°C) under consideration. The expression for λ_2 reveals that the value λ_2 is negative for heating ($T_w > T_\infty$) and positive for cooling ($T_w < T_\infty$). In addition, the unstable layer is always confined to the region near the plate and instability occurs only when $T_w \geq 4^\circ\text{C}$ for heating from below ($T_w > T_\infty$), and when $T_w < 4^\circ\text{C}$ for cooling from below ($T_w < T_\infty$).

Noting the basic flow quantities in the following form

$$U_b = U_\infty f'(\eta), \quad V_b = (U_\infty/2\text{Re}_L)(\eta f' - f) = (U_\infty/\text{Re}_L)F \quad (13)$$

where $\text{Re}_L = U_\infty L/\nu = (U_\infty X/\nu)^{1/2} = \text{Re}_X^{1/2}$, $F = (\eta f' - f)/2$ and introducing the following dimensionless variables, $(x, y = \eta, z) = (X, Y, Z)/L$, $(u, v, w) = (U', V', W')/U_\infty$, $p = P'/(\rho U_\infty^2/\text{Re}_L)$, $\theta = \Theta'/\Delta T$ the disturbance equations in linearized dimensionless form become

$$\frac{\partial v}{\partial y} + \frac{\partial w}{\partial z} = 0 \quad (14)$$

$$\nabla^2 u - F \frac{\partial u}{\partial y} + \frac{1}{2} \eta f'' u = \text{Re}_L f'' v \quad (15)$$

$$\nabla^2 v - F \frac{\partial v}{\partial y} - \frac{1}{2} \eta f'' v = \frac{\partial p}{\partial y} - G(1 - \lambda_1 \phi + \lambda_2 \phi^2) \theta \quad (16)$$

$$\nabla^2 w - F \frac{\partial w}{\partial y} = \frac{\partial p}{\partial z} \quad (17)$$

$$\nabla^2 \theta - \text{Pr} F \frac{\partial \theta}{\partial y} = \text{Pr} \tau' (\text{Re}_L v - \frac{1}{2} \eta u) \quad (18)$$

where $G = (\nu/U_\infty L)(gL^3/\nu^2)(\Delta T)[2\gamma_1(A\Delta T)\{1 + (3\gamma_2/2\gamma_1)(A\Delta T)\}]$
 $= \text{Gr}_L/\text{Re}_L$, $\text{Gr}_L = (gL^3/\nu^2)(\Delta T)[2\gamma_1(A\Delta T)\{1 + (3\gamma_2/2\gamma_1)(A\Delta T)\}]$

where $\nabla^2 = \partial^2/\partial y^2 + \partial^2/\partial z^2$. In the expression for Gr_L , one

can readily recognize the quantity inside the square brackets as the equivalent coefficient of thermal expansion. Furthermore, the instability is possible with heating or cooling from below because of the presence of $(\Delta T)^2$. Upon eliminating p and w from equations (16) and (17) using continuity equation (14), one obtains

$$\nabla^2 \nabla^2 v - F \frac{\partial}{\partial y} \nabla^2 v - \frac{1}{2} \eta f'' \nabla^2 v = -G(1 - \lambda_1 \phi + \lambda_2 \phi^2) \frac{\partial^2 \theta}{\partial z^2} \quad (19)$$

The boundary conditions are $u = v = v' = \theta = 0$ at $y = 0$ and ∞ .

For the stationary longitudinal vortices, the following disturbance forms are applicable for the present neutral stability analysis [13,14].

$$[u, v, \theta] = [u^+(y), v^+(y), \theta^+(y)] \exp(iaz) \quad (20)$$

Substituting equation (20) into equations (15), (19) and (18) and further resetting $u^+ = \text{Re}_L u^*$, $v^+ = v^*$, $\theta^+ = \text{Re}_L \theta^*$, one obtains

$$[(D^2 - a^2) - FD + \frac{1}{2} \eta f''] u^* = f'' v^* \quad (21)$$

$$\begin{aligned} & [(D^2 - a^2)^2 - F(D^2 - a^2)D - \frac{1}{2} \eta f''(D^2 - a^2)]v^* \\ & = a^2 Gr_L (1 - \lambda_1 \phi + \lambda_2 \phi^2) \theta^* \end{aligned} \quad (22)$$

$$[(D^2 - a^2) - Pr FD] \theta^* = Pr \tau' (v^* - \frac{1}{2} \eta u^*) \quad (23)$$

where $D = d/dy$. The boundary conditions are

$$u^* = v^* = Dv^* = \theta^* = 0 \text{ at } y = 0 \text{ and } \infty. \quad (24)$$

It is seen that the present eighth order eigenvalue problem is independent of Reynolds number Re_L . For given Pr , λ_1 and λ_2 , there exists the functional dependence of Gr_L on a and the minimum critical value of Gr_L corresponding to the onset of longitudinal rolls with axes in the direction of the steady flow is sought. With the existence of laminar main flow, the analytical solution does not appear to be practical and a numerical method of solution is employed.

10.3 Method of Solution

The high order finite-difference scheme due to Thomas [15] is used in the present study. The detailed derivation is also given by Chen [16]. In carrying out the numerical solution, it is necessary to assign a finite value of η to

satisfy the boundary conditions at $\eta = \infty$ [17]. With $Pr = 10$, the thermal boundary layer is inside the hydrodynamic boundary layer. After numerical experiments, the conditions at infinity for θ^* and v^* are replaced by those at $\eta = 5.0$ corresponding to $\tau \leq 10^{-8}$ since as $\tau \rightarrow 0$, one has $\tau' \rightarrow 0$. An examination of equations (22) and (23) reveals that the flow field is stable for the region $\eta = 5.0 \sim \infty$. On the other hand, the condition for u^* at $\eta = \infty$ is also set at $\eta = 5.0$ since v^* vanishes for $\eta \geq 5.0$ in equation (21). It is of interest to note that at $\eta = 10.4$ one has $(f' - 1) \leq 10^{-8}$ and $f'' \rightarrow 0$ for the region $\eta = 10.4 \sim \infty$. In addition, the step size $\Delta y = 0.02$ and the number of divisions $M = 250$ are found to be satisfactory.

The finite difference transformation of equation (22) and its boundary conditions leads to a quidiagonal system [18] of matrix for a set of algebraic equations and similarly two tridiagonal systems [19] result from equations (21) and (23) with their boundary conditions. Since the dependent variables are all coupled through a set of equations (21) to (23), an iterative procedure with the following main steps is used for the numerical solution. It is noted that the basic velocity and temperature distributions are known and $Pr = 10$.

1. The initial values for wave number a and eigenvalue Gr_L are assumed. The disturbance velocity v_k^* is taken as $v_k^* = 2(1 - k/M)$, $k = 2, 3, \dots, M$.

2. The finite-difference solution of equation (21)

yields u_k^* .

3. After knowing v_k^* and u_k^* , equation (23) is solved to obtain o_k^* .

4. The right-hand side of equation (22) is now known and new values for v_k^* can be found.

5. A new and improved eigenvalue can be computed by using the following equation [20].

$$(Gr_L)_{new} = (Gr_L)_{old} \frac{[\sum_k (v_k^*_{old})^2]^{1/2}}{[\sum_k (v_k^*_{new})^2]^{1/2}} \quad (25)$$

The magnitude of the quantity v_k^* is readjusted by the following equation in order to return to the original order for computation.

$$v_k^* = (v_k^*_{new}) (Gr_L)_{new} / (Gr_L)_{old} \quad (26)$$

6. The steps (2) to (4) are repeated until the following convergence criterion is satisfied.

$$\sum_k |(v_k^*_{new}) - (v_k^*_{old})| / \sum_k |(v_k^*_{new})| \leq 10^{-6} \quad (27)$$

Numerical experiments show that only a few iterations are required to satisfy the above condition and five significant

figures for critical Gr_L are found to be correct.

10.4 Results and Discussion

The present numerical solution also yields results for secondary flow pattern and disturbance profiles for u^* , v^* and θ^* in addition to neutral stability results. The results are presented in Figs. 1 to 4 for some typical cases. The stream function ψ defined by $v = \partial\psi/\partial z$ and $w = -\partial\psi/\partial y$ can be obtained by considering the normal modes of the disturbances, $v = v^+(y)e^{iaz}$ and $\psi = \psi^+(y)e^{iaz}$, as

$$\psi = - [i v^*(y)/a] e^{iaz} \quad (28)$$

The contour lines shown in Figs. 1 and 2 for heating and cooling from below, respectively, are obtained by noting that physical meaning is attached only to the real part of the stream function. In Fig. 3, the magnitude of the maximum disturbance quantity is taken to be 0.1 and the disturbance amplitudes are superimposed on basic quantities. The horizontal disturbance velocity amplitude u^* is seen to be negative suggesting that the secondary flow also derives its energy from the main flow.

The neutral results for the critical values of the Grashof number Gr_L^* and the corresponding a^* are listed in Table 1 and also plotted in Fig. 5. The marginal stability curves are shown in Fig. 6 for illustration.

In interpreting the numerical results, one notes that the parameters λ_1 and λ_2 depend on A as well as ΔT ($T_w - T_\infty$). When ΔT and $(T_w - T_{\max})$ are known, λ_1 and λ_2 can be computed. Because of the rather complicated expressions for λ_1 and λ_2 , one cannot readily understand the physical situation corresponding to a particular combination of λ_1 and λ_2 . In Fig. 5, the effect of λ_1 on Gr_L^* may be understood by considering the case of $\lambda_2 = 0$ representing a parabolic density-temperature relationship. For this case, one obtains $\lambda_1 = -A^{-1} = -(T_w - T_\infty)/(T_w - T_{\max})$ and it is seen that for a given $(T_w - T_\infty) = \Delta T$, the magnitude of λ_1 increases as the temperature difference $(T_w - T_{\max})$ decreases. When $(T_w - T_{\max})$ is small, the unstable liquid layer near the plate is small and consequently it is more stable as represented by higher Gr_L^* . In Table 1, the numerical solution does not converge for higher Gr_L^* than those listed. This is presumably due to the rather thin unstable layer requiring a yet larger number of divisions M . For a given λ_1 , the liquid layer becomes more stable as λ_2 decreases.

The theoretical results for the critical Rayleigh numbers reported in [5] for the stationary horizontal liquid layers with both rigid-rigid and rigid-free surface conditions agree excellently with the experimental results. With the exception of the characteristic length, the present definition of the Grashof number is comparable to that used in [5,21]. Although the present instability problem with steady laminar main flow (Blasius flow) is different from

that of a horizontal liquid layer without main flow, the trend of the instability results regarding λ_1 and λ_2 effects shown in Table 1 agrees with those listed in [21]. It is of some interest to compare the present instability results with those of the rigid-rigid case reported in [5,21] since the boundary conditions for the disturbance quantities are comparable. For given A , ΔT or λ_1 , λ_2 , the ratio of the critical Gr_L^* from this study over that of [5,21] simply becomes $Gr_L^*/(Gr_d)_{cr} = (L/d)^3$ where d = liquid layer thickness [5]. At this point, it appears to be more reasonable to use the thermal boundary layer thickness δ_T instead of the characteristic length L for the comparison. From the boundary layer theory [12], it is known that $\delta_T/\delta = Pr^{-1/3}$ approximately with $\delta = 5.83(\nu x/U_\infty)^{1/2} = 5.83L$. It is then found that $L = 0.370 \delta_T$ and the ratio becomes $Gr_L^*/(Gr_d)_{cr} = 0.051$ after setting $\delta_T = d$. On the other hand, the ratio $Gr_L^*/(Gr_d)_{cr}$ based on numerical results from this study and Table 2 of [21] gives the value which is approximately one order higher than the value of 0.051. This suggests immediately that the above rather simple intuitive comparison is not correct. However, the above simple discussion serves to emphasize the essential difference between the present instability problem and the classical Benard problem with maximum density effect [5,21].

10.5 Concluding Remarks

1. In contrast to the classical Benard problem, the

present thermal instability problem for the Blasius flow is characterized by the existence of the stable upper liquid layer above the unstable lower layer near the plate. With $Pr = 10$, it is known that $\delta_T/\delta = 0.464$ and the thermal boundary layer is inside the hydrodynamic boundary layer. The basic temperature profile for the present instability problem is non-linear.

2. By using the characteristic length L , the eigenvalue Gr_L^* is shown to be independent of Re_L . To study the Reynolds number effect based on the familiar definition $Re_X = (U_\infty X/\nu)$, one must use the relationship $Gr_L = Gr_X/Re_L^3 = Gr_X/Re_X^{3/2}$ where $Gr_X = (gX^3/\nu^2)(\Delta T)[2\gamma_1(A\Delta T)\{1 + (3\gamma_2/2\gamma_1)(A\Delta T)\}]$.

3. In applying the present instability results, it is useful to recall that the approximate limits of the laminar boundary layer theory are $0[10^2] < Re_X \leq 5 \times 10^5$. The experimental data do not seem to be available for comparison with the present theoretical results.

CHAPTER XI

CONCLUSIONS

11.1 Scope of Results

This thesis investigates a class of thermal instability problems involving plane Poiseuille, Hartmann and Blasius flows. The onset of secondary flow driven by buoyancy force for the above mentioned fully developed laminar flow is of considerable practical interest since after the onset of instability the flow takes on a three-dimensional character and the heat transfer rate is expected to increase with Rayleigh number. The flow configurations under consideration occur in many industrial operations and processes and the critical Rayleigh numbers marking the onset of instability are required in design. For the case of plane Poiseuille flow in the thermal entrance region of a horizontal parallel-plate channel heated from below, both the longitudinal and transverse vortex disturbances are considered. For each linear instability analysis, typical numerical instability results are obtained to clarify the various physical effects. Among the various physical effects considered, the maximum density effects on convective instability of water layer with main flow is noteworthy since the instability results are applicable to the melting of ice or ice formation involving main flow. It should be

pointed out that the basic flow and temperature fields upon which the instability problem is considered neglects the free convection effect and the basic velocity profile remains to be plane Poiseuille, Hartmann or Blasius flow. Thus, the problem is to find the condition at which the free convection starts to affect the main flow. Furthermore, it is assumed that the instability sets in as stationary convection since the stationary longitudinal vortices are observed in experiments. The assumption is also consistent with previous investigations.

Besides the convective instability in horizontal fluid flows, the maximum density effects on thermal instability in a thin horizontal water layer driven by combined buoyancy and surface tension gradients are investigated. The problem represents an extension of Nield's linear stability analysis in 1964 to water in the temperature range $0 \sim 30^\circ\text{C}$.

The coupled perturbation equations for each instability problem are solved by a higher order finite-difference method using an iterative procedure. It is found that the iterative numerical solution is very efficient and powerful for the present instability problems. Apparently, the numerical technique has a wide applicability for the related instability problems.

11.2 Conclusions and Significance

The low Peclet number convective heat transfer problem in the thermal entrance region of a parallel-plate channel

with unequal constant wall temperatures is approached by the eigenfunction expansion method employing the Gram-Schmidt orthonormalization procedure. When $Pe \leq 10$, the axial heat conduction effect on heat transfer is considerable but when $Pe \geq 50$, the axial heat conduction may be negligible. The critical Rayleigh numbers versus the channel distance are determined for both upstream and downstream regions of the channel with $Pe = 1, 5, 10$. For $Pe = 50$, instability results are obtained for downstream region only. It is established that the transverse vortex disturbances are the preferred mode over the longitudinal vortex disturbances for $Pe \leq 1$ and $Pr \geq 1$ (or low Reynolds number flow), in the regions upstream and downstream of the thermal entrance. For other conditions, the longitudinal vortex rolls have priority of occurrence. It is noted that generally the axial heat conduction has a destabilizing effect in the upstream region and a stabilizing effect in the downstream region. The theoretical instability results considering maximum density effects for water in the temperature $0 \sim 30^\circ\text{C}$ are useful in assessing the free convection effect on freezing or thawing in channel flow of water. The viscous dissipation effect on convective instability is qualitatively similar to that of internal heat generation in a horizontal fluid layer and represents a destabilizing influence. It is found that the viscous dissipation effect is significant for $Pr \geq 10$ but is insignificant for $Pr \leq 0.7$.

The basic flow solution for Hartmann flow considers

the effects of axial conduction, viscous dissipation and Joulean heating but neglects the axial heat penetration through the thermal entrance. The magnetic Reynolds number is assumed to be small and the Hall effect is neglected. When the magnetic Reynolds number is very small compared to unity, the magnetic field is not distorted by the flow. In engineering problems, it is difficult to obtain the magnetic Reynolds number greater than unity because of the low electrical conductivity of the useful fluids. The Hall effect can be neglected when the fluid has a scalar electrical conductivity. The convective instability analysis of horizontal Hartmann flow in the thermal entrance region of a parallel-plate channel considers the effects of Prandtl, Peclet, Brinkman and Hartmann numbers. It is found that the magnetic field has a stabilizing effect and a decrease in Prandtl number has a destabilizing effect in the thermal entrance region.

The maximum density effects on thermal instability driven by combined buoyancy and surface tension provide further physical insight into the thermal instability problem discussed by Nield in 1964. The instability results may have direct applications in predicting the onset of convection in surface melting involving ice layer on a northern lake or pond. Similarly, one is also interested in predicting the onset of convection in a thin freezing water layer.

The convective instability analysis of laminar forced convection along a horizontal semi-infinite flat plate with

uniform wall temperature is believed to be one of the basic problems and complements the hydrodynamic instability analysis of laminar boundary layers reported in the literature. The maximum density effects on convective instability of horizontal laminar boundary layer are studied in order to predict the onset of free convection effect in laminar boundary layers along ice surface where melting or solidification occurs.

11.3 Recommendations

This theoretical investigation demonstrates the applicability of the numerical method in predicting the critical Rayleigh number for various thermal instability problems. It is believed that the numerical method used is a powerful one and can be applied to many linear instability analyses which remain to be explored in future.

Experimental verification is required to substantiate the theoretical results reported in this thesis. The experimental investigations on the increase of heat transfer rate with the increase of Rayleigh number after the onset of instability may pave the way for theoretical investigations on finite amplitude convection problems.

Future investigations on convective instability of MHD channel flows may include the influence of Hall effect and iron slip in addition to the viscous dissipation, Joule heating and axial heat conduction effects. In the present analysis of thermal instability for Blasius flows along a

horizontal plate, the free convection effects are not considered in the basic flow solution. Because of practical interest in the prediction of the onset of thermal instability in flow over a horizontal flat plate, the thermal instability of combined forced and free laminar convection along a horizontal flat plate with respect to stationary longitudinal vortex disturbances should be investigated in future. Finally, one notes that the thermal radiation effects on convective instability of various horizontal fluid flows may prove to be fruitful and important research topics for future theoretical investigations.

APPENDIX 1

DERIVATION OF HIGH ORDER FINITE- DIFFERENCE APPROXIMATION

The high order finite-difference approximation due to Thomas [1], who used it in a study on the stability of Plane Poiseuille flow, is employed in this thesis for the numerical solution of the thermal instability problems. The detailed derivation of the approximation is given by Chen [2] in a study on the hydrodynamic stability of developing flow in a parallel-plate channel. For convenience, the derivation is summarized here.

The various orders of derivatives of a function $g(z)$ can be expressed in finite-difference form as:

$$Dg = \frac{1}{h} \left\{ u\delta - \frac{1}{6} u\delta^3 + \frac{1}{30} u\delta^5 - \frac{1}{140} u\delta^7 + \frac{1}{630} u\delta^8 \dots \right\} g \quad (1)$$

$$D^2g = \frac{1}{h^2} \left\{ \delta^2 - \frac{1}{12} \delta^4 + \frac{1}{90} \delta^6 - \frac{1}{560} \delta^8 + \dots \right\} g \quad (2)$$

$$D^3g = \frac{1}{h^3} \left\{ u\delta^3 - \frac{1}{4} u\delta^5 + \frac{7}{120} u\delta^7 \dots \right\} g \quad (3)$$

$$D^4 g = \frac{1}{h^4} \{ \delta^4 - \frac{1}{6} \delta^6 + \frac{7}{240} \delta^8 \dots \} g \quad (4)$$

$$D^5 g = \frac{1}{h^5} \{ u \delta^5 - \frac{1}{3} u \delta^7 + \dots \} g \quad (5)$$

$$D^6 g = \frac{1}{h^6} \{ \delta^6 - \frac{1}{4} \delta^8 + \dots \} g \quad (6)$$

$$D^7 g = \frac{1}{h^7} \{ u \delta^7 \dots \} g \quad (7)$$

$$D^8 g = \frac{1}{h^8} \{ \delta^8 \dots \} g \quad (8)$$

where D is the linear operator, $D \equiv d/dz$, and h the finite-difference mesh size.

By defining the averaging operator u , and the central difference operator δ , one obtains

$$ug(z) = \frac{1}{2} [g(z + \frac{h}{2}) + g(z - \frac{h}{2})] \quad (9)$$

$$\delta g(z) = g(z + \frac{h}{2}) - g(z - \frac{h}{2}) \quad (10)$$

and

$$\delta^{n+1} g(z) = \delta^n g(z + \frac{h}{2}) - \delta^n g(z - \frac{h}{2}), \quad n=1,2,3,\dots \quad (11)$$

$$u\delta^{n+1}g(z) = \frac{1}{2} [\delta^{2n+1}g(z + \frac{h}{2}) + \delta^{2n+1}g(z - \frac{h}{2})],$$

$$n = 0, 1, \dots \quad (12)$$

In order to reduce the truncation error, Thomas [1] introduced a new variable g relating to the dependent variable, say ϕ , and its derivatives by the expression

$$-\frac{1}{6} \delta^2 D^2 \phi + \frac{1}{90} h^4 D^4 \phi \quad (13)$$

By substituting this new variable into equations (1) to (8), it can be shown that the truncation errors in ϕ and its derivatives become of higher order [2]. One thus obtains

$$\begin{aligned} hD\phi = & \{u\delta - \frac{1}{6} u\delta^3 + \frac{1}{30} u\delta^5 - \frac{1}{140} u\delta^7 + \dots\}g \\ & + \frac{1}{6} h^3 D^3 \phi - \frac{1}{90} h^5 D^5 \phi \end{aligned} \quad (14)$$

$$\begin{aligned} h^2 D^2 \phi = & \{\delta^2 - \frac{1}{12} \delta^4 + \frac{1}{90} \delta^6 - \frac{1}{560} \delta^8 + \dots\}g \\ & + \frac{1}{6} h^4 D^4 \phi - \frac{1}{90} h^6 D^6 \phi \end{aligned} \quad (15)$$

$$h^3 D^3 \phi = \left\{ u \delta^3 - \frac{1}{4} u \delta^5 + \frac{7}{120} u \delta^7 \dots \right\} g + \frac{1}{6} h^5 D^5 \phi - \frac{1}{90} h^7 D^7 \phi \quad (16)$$

$$h^4 D^4 \phi = \left\{ \delta^4 - \frac{1}{6} \delta^6 + \frac{7}{240} \delta^8 \dots \right\} g + \frac{1}{6} h^6 D^6 \phi - \frac{1}{90} h^8 D^8 \phi \quad (17)$$

$$h^5 D^5 \phi = \left\{ u \delta^5 - \frac{1}{3} u \delta^7 + \dots \right\} g + \frac{1}{6} h^7 D^7 \phi - \frac{1}{90} h^9 D^9 \phi \quad (18)$$

$$h^6 D^6 \phi = \left\{ \delta^6 - \frac{1}{6} \delta^8 + \dots \right\} g + \frac{1}{6} h^8 D^8 \phi - \frac{1}{90} h^{10} D^{10} \phi \quad (19)$$

$$h^7 D^7 \phi = \left\{ u \delta^7 \dots \right\} g + \frac{1}{6} h^9 D^9 \phi - \frac{1}{90} h^{11} D^{11} \phi \quad (20)$$

$$h^8 D^8 \phi = \left\{ \delta^8 + \dots \right\} g + \frac{1}{6} h^{10} D^{10} \phi - \frac{1}{90} h^{12} D^{12} \phi \quad (21)$$

For even order, one may approximate equation (21) as

$$h^8 D^8 \phi = \delta^8 g \quad (22)$$

where the terms of order h^{10} and higher order are neglected.

Substituting equation (22) into equation (19), and successively using these results from equations (17), (15),

and (13), one obtains

$$h^6 D^6 \phi = \{ \delta^6 - \frac{1}{12} \delta^8 \} g \quad (23)$$

$$h^4 D^4 \phi = \{ \delta^4 - \frac{1}{240} \delta^8 \} g \quad (24)$$

$$h^2 D^2 \phi = \{ \delta^2 + \frac{1}{12} \delta^4 - \frac{1}{6048} \delta^8 \} g \quad (25)$$

$$\phi = \{ 1 + \frac{1}{6} \delta^2 + \frac{1}{360} \delta^4 - \frac{67}{907200} \delta^8 \} g \quad (26)$$

Similarly, for odd order, equation (20) becomes

$$h^7 D^7 \phi = u \delta^7 g \quad (27)$$

Equations (18), (16), and (14) thus become

$$h^5 D^5 \phi = \{ u \delta^5 - \frac{1}{6} u \delta^7 \} g \quad (28)$$

$$h^3 D^3 \phi = \{ u \delta^3 - \frac{1}{12} u \delta^5 - \frac{11}{360} u \delta^7 \} g \quad (29)$$

$$h D \phi = \{ u \delta + \frac{3}{40} u \delta^3 \} g \quad (30)$$

Since the highest order of the governing differential equation is fourth order, equations (24), (25), (26), (29), and (30) can be written in the form as

$$\begin{pmatrix} \phi \\ hD\phi \\ h^2 D^2 \phi \\ h^3 D^3 \phi \\ h^4 D^4 \phi \end{pmatrix} = \begin{pmatrix} 1 & 0 & \frac{1}{6} & 0 & \frac{1}{360} \\ 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 & \frac{1}{12} \\ 0 & 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 0 & 1 \end{pmatrix} \begin{pmatrix} g \\ u\delta g \\ \delta^2 g \\ u\delta^3 g \\ \delta^4 g \end{pmatrix} + \begin{pmatrix} \epsilon_0 \\ h\epsilon_1 \\ h^2\epsilon_2 \\ h^3\epsilon_3 \\ h^4\epsilon_4 \end{pmatrix} \quad (31)$$

where $\epsilon_0 = \frac{-67}{907200} h^8 D^8 \phi$, $\epsilon_3 = \frac{-1}{12} h^2 D^5 \phi$

$$\epsilon_1 = \frac{1}{120} h^4 D^5 \phi; \quad \epsilon_4 = \frac{1}{240} h^4 D^8 \phi \quad (32)$$

$$\epsilon_2 = \frac{-67}{6048} h^6 D^8 \phi$$

By using equations (9) to (11), one obtains

$$\begin{pmatrix} g \\ u\delta g \\ \delta^2 g \\ u\delta^3 g \\ \delta^4 g \end{pmatrix} = \begin{pmatrix} 0 & 0 & 1 & 0 & 0 \\ 0 & -\frac{1}{2} & 0 & \frac{1}{2} & 0 \\ 0 & 1 & -2 & 1 & 0 \\ -\frac{1}{2} & 1 & 0 & -1 & -\frac{1}{2} \\ 1 & -4 & 6 & -4 & 1 \end{pmatrix} \begin{pmatrix} g(z-2h) \\ g(z-h) \\ g(z) \\ g(z+h) \\ g(z+2h) \end{pmatrix} \quad (33)$$

Substituting equation (33) into (31), one obtains

$$\begin{pmatrix} \phi \\ hD\phi \\ h^2 D^2 \phi \\ h^3 D^3 \phi \\ h^4 D^4 \phi \end{pmatrix} = \begin{pmatrix} \frac{1}{360} & \frac{7}{45} & \frac{41}{60} & \frac{7}{45} & \frac{1}{360} \\ 0 & -\frac{1}{2} & 0 & \frac{1}{2} & 0 \\ \frac{1}{12} & \frac{2}{3} & -\frac{3}{2} & \frac{2}{3} & \frac{1}{12} \\ -\frac{1}{2} & 1 & 0 & -1 & \frac{1}{2} \\ 1 & -4 & 6 & -4 & 1 \end{pmatrix} \begin{pmatrix} g(z-2h) \\ g(z-h) \\ g(z) \\ g(z+h) \\ g(z+2h) \end{pmatrix} + \begin{pmatrix} 0 \\ h\epsilon_1 \\ h^2\epsilon_2 \\ h^3\epsilon_3 \\ h^4\epsilon_4 \end{pmatrix} \quad (34)$$

which is the resulting matrix for the differential equation of order four.

Similarly, for the differential equation of order two, one can use the following matrix

$$\begin{pmatrix} \phi \\ hD\phi \\ h^2 D^2 \phi \end{pmatrix} = \begin{pmatrix} \frac{1}{12} & \frac{5}{6} & \frac{1}{12} \\ -\frac{1}{2} & 0 & \frac{1}{2} \\ 1 & -2 & 1 \end{pmatrix} \begin{pmatrix} g(z-h) \\ g(z) \\ g(z+h) \end{pmatrix} + \begin{pmatrix} 0 \\ h\epsilon_1 \\ h^2 \epsilon_2 \end{pmatrix} \quad (35)$$

where

$$\epsilon_0 = -\frac{1}{4320} h^6 D^6 \phi,$$

$$\epsilon_1 = -\frac{1}{12} h^2 D^3 \phi, \quad (36)$$

$$\epsilon_2 = -\frac{1}{360} h^4 D^5 \phi.$$

APPENDIX 2

ALGORITHMS FOR PENTADIAGONAL AND
TRIDIAGONAL MATRICES

1. Algorithm for Pentadiagonal Matrix [3]

$$a_i u_{i-2} + b_i u_{i-1} + c_i u_i + d_i u_{i+1} + e_i u_{i+2} = f_i$$

for $1 \leq i \leq R$ with $a_1 = b_1 = a_2 = e_{R-1} = d_R = e_R = 0$.

The algorithm is as follows. First compute

$$\delta_1 = d_1/c_1, \lambda_1 = e_1/c_1, \gamma_1 = f_1/c_1$$

and

$$\mu_2 = c_2 - b_2 \delta_1, \delta_2 = (d_2 - b_2 \lambda_1)/\mu_2,$$

$$\lambda_2 = e_2/\mu_2, \gamma_2 = (f_2 - b_2 \gamma_1)/\mu_2$$

Then for $3 \leq i \leq (R-2)$, compute

$$\beta_i = b_i - a_i \delta_{i-2}$$

$$\mu_i = c_i - \beta_i \delta_{i-1} - \lambda_{i-2}$$

$$\delta_i = (d_i - \beta_i \lambda_{i-1}) / \mu_i$$

$$\lambda_i = e_i / \mu_i$$

$$Y_i = (f_i - \beta_i Y_{i-1} - a_i Y_{i-2}) / \mu_i$$

Next compute

$$\beta_{R-1} = b_{R-1} - a_{R-1} \delta_{R-3}$$

$$\mu_{R-1} = c_{R-1} - \beta_{R-1} \delta_{R-2} - a_{R-1} \lambda_{R-3}$$

$$\delta_{R-1} = (d_{R-1} - \beta_{R-1} \lambda_{R-2}) / \mu_{R-1}$$

$$Y_{R-1} = (f_{R-1} - \beta_{R-1} Y_{R-2} - a_{R-1} Y_{R-3}) / \mu_{R-1}$$

and

$$\beta_R = b_R - a_R \delta_{R-2}$$

$$\mu_R = c_R - \beta_R \delta_{R-1} - a_R \lambda_{R-2}$$

$$\gamma_R = (f_R - \beta_R \gamma_{R-1} - a_R \gamma_{R-2}) / \mu_R$$

The β_i and μ_i are used only to compute δ_i , λ_i and γ_i , and need not be stored after they are computed. The δ_i , λ_i and γ_i must be stored, as they are used in the back solution. This is

$$u_R = \gamma_R$$

$$u_{R-1} = \gamma_{R-1} - \delta_R u_R$$

and $u_i = \gamma_i - \delta_i u_{i+1} - \delta_{i+1} u_{i+2}$ for $(R-2) \geq i \geq 1$.

2. Algorithm for Tridiagonal Matrix [4].

$$a_i v_{i-1} + b_i v_i + c_i v_{i+1} = d_i$$

for $1 \leq i \leq N$ with $a_1 = c_N = 0$. The algorithm is as follows.

First compute

$$\beta_1 = b_1, \gamma_1 = d_1/\beta_1$$

Then for $2 \leq i \leq N$, compute

$$\beta_i = b_i - a_i c_{i-1}/\beta_{i-1}$$

$$\gamma_i = (d_i - a_i \gamma_{i-1})/\beta_i$$

The β_i and γ_i must be stored, as they are used in the back solution. This is

$$v_N = \gamma_N$$

and $v_i = \gamma_i - c_i v_{i+1}/\beta_i$ for $(N-1) \geq i \geq 1$.

APPENDIX 3

METHOD OF REGRESSION FOR TEMPERATURE
EFFECTS ON DENSITY OF WATER BETWEEN 0°C
AND 30°C [5].

Consider the relationship,

$$\rho = \rho_{\max} [1 - \gamma_1 (T - T_{\max})^2 - \gamma_2 (T - T_{\max})^3]$$

and setting $y = \rho$, $x = T - T_{\max}$, $c_1 = T_{\max}$, and $c_2 = \rho_{\max}$,
one obtains

$$y = c_2 [1 + a_1 x^2 + a_2 x^3]$$

where $a_1 = -\gamma_1$, and $a_2 = -\gamma_2$.

From Dorsey's Table [6], one obtains 310 pairs of
values for the temperature range 0 ~ 30°C as,

$$x_1, x_2, \dots, x_n,$$

$$y_1, y_2, \dots, y_n, \quad n = 310$$

The error in the fitting, that is, the residual ϵ_i , is given by

$$\epsilon_i = y_i - c_2(1 + a_1 x_i^2 + a_2 x_i^2)$$

The sum of the squares of the residuals is given by

$$P = \sum \epsilon_i^2$$

Minimizing P , one obtains

$$\frac{\partial P}{\partial a_1} = 0, \quad \frac{\partial P}{\partial a_2} = 0$$

i.e.,

$$\sum a_1 x_i^4 + \sum a_2 x_i^5 = \sum y_i x_i^2 - \sum c_2 x_i^2$$

$$\sum a_1 x_i^5 + \sum a_2 x_i^6 = \sum y_i x_i^3 - \sum c_2 x_i^3$$

Solving the above set of equations, one obtains

$$a_1 = \frac{\begin{vmatrix} \sum y_i x_i^2 - \sum c_2 x_i^2 & \sum x_i^5 \\ \sum y_i x_i - \sum c_2 x_i^3 & \sum x_i^6 \end{vmatrix}}{D}$$

$$a_2 = \frac{\begin{vmatrix} \sum x_i^4 & \sum y_i x_i^2 - \sum c_2 x_i^2 \\ \sum x_i^5 & \sum y_i x_i - \sum c_2 x_i^3 \end{vmatrix}}{D}$$

$$\text{where } D = \begin{vmatrix} \sum x_i^4 & \sum x_i^5 \\ \sum x_i^5 & \sum x_i^6 \end{vmatrix}$$

The numerical results are

$$\gamma_1 = 7.731937895 \times 10^{-6}$$

$$\gamma_2 = -5.182117468 \times 10^{-8}$$

$$\gamma_2/\gamma_1 = -6.70222334 \times 10^{-3}$$

$$\text{standard deviation} = 3.797 \times 10^{-6}$$

In Table A1, Column A represents the values listed in Table 93 of [6], and Column B lists the values calculated by equation (1) using the results of the regression analysis.

APPENDIX 4

PROOF FOR $e_x^+ = e_y^+ = e_z^+ = b_x^+ = 0$

1. From equation (22b) and considering the z-component, one obtains

$$\frac{\partial e_x^+}{\partial y} = \frac{\partial e_y^+}{\partial x}$$

By using the disturbance form $f = f^+(z)e^{iay}$, one obtains

$$iae_x^+ = 0$$

Hence $e_x^+ = 0$ for the whole domain.

2. From equation (21) and the boundary condition (29), one has

$$j_z = ke_z + \phi_u b_y$$

$$j_z = 0, \quad \text{at } z = 0, 1$$

Since $\phi_u = 0$ at $z = 0, 1$, one obtains

$$e_z = 0 \quad \text{at } z = 0, 1$$

This implies that

$$e_z^+ = 0 \quad \text{at } z = 0, 1$$

From the z -component of the electric field equation one obtains

$$(D^2 - a^2)e_z^+ = 0$$

Thus one concludes that $e_z^+ = 0$ for the whole domain.

3. From equation (22d), the z -component gives

$$2\text{Rmj}_z = \left(\frac{\partial b_y}{\partial x} - \frac{\partial b_x}{\partial y} \right) = 0, \quad \text{at } z = 0, 1$$

This implies

$$b_x^+ = 0 \quad \text{at } z = 0, 1$$

After the order of magnitude analysis, equation (34) becomes

$$(D^2 - a^2)b_x^+ = 0$$

Hence, one concludes that $b_x^+ = 0$ for the whole domain.

4. The y-component of equation (22d) is

$$2\text{Rm}j_y = \left(\frac{\partial b_x}{\partial z} - \frac{\partial b_z}{\partial x} \right)$$

In terms of the amplitude quantities, one obtains

$$2\text{Rm}j_y^+ = Db_x^+$$

Since $b_x^+ = 0$ for the whole domain, one concludes that $j_y^+ = 0$ for the whole domain. From equation (21) one has

$$j_y = ke_y - u - \phi_u b_z$$

Since $u = \phi_u = 0$ at $z = 0, 1$, and $j_y^+ = 0$ for the whole domain, one obtains

$$e_y^+ = 0 \text{ at } z = 0, 1$$

From equation (36) one has

$$(D^2 - a^2)e_y^+ = 0$$

Hence one concludes that $e_y^+ = 0$ for the whole domain.

APPENDIX 5

DERIVATION OF STREAM FUNCTION FOR
HEXAGONAL CELL [7]

The perturbation equations in dimensionless form are:

$$\frac{\partial u}{\partial x} + \frac{\partial v}{\partial y} + \frac{\partial w}{\partial z} = 0 \quad (1)$$

$$\frac{\partial u}{\partial t} = - \frac{\partial P}{\partial x} + \nu^2 \nabla^2 u \quad (2)$$

$$\frac{\partial v}{\partial t} = - \frac{\partial P}{\partial y} + \nu^2 \nabla^2 v \quad (3)$$

$$\frac{\partial w}{\partial t} = - \frac{\partial P}{\partial z} + \nu^2 \nabla^2 w + Gr(1 + \lambda_1 z + \lambda_2 z^2) \theta \quad (4)$$

Taking partial derivative of equation (2) with respect to y minus partial derivatives of equation (3) with respect to x , one obtains

$$\left[\frac{\partial}{\partial t} - \nu^2 \nabla^2 \right] \left(\frac{\partial u}{\partial x} - \frac{\partial v}{\partial y} \right) = 0 \quad (5)$$

This equation can be solved by writing

$$u = -\frac{\partial \Phi}{\partial x} - \frac{\partial \Psi}{\partial y}, \quad v = -\frac{\partial \Phi}{\partial y} + \frac{\partial \Psi}{\partial x} \quad (6)$$

where Φ is unrestricted and

$$\left[\frac{\partial}{\partial t} - v^2 \right] \nabla_1^2 \psi = 0 \quad (7)$$

$$\nabla_1^2 = \frac{\partial^2}{\partial x^2} + \frac{\partial^2}{\partial y^2}$$

Then the continuity equation requires that

$$\frac{\partial w}{\partial z} = -\left(\frac{\partial u}{\partial x} + \frac{\partial v}{\partial y} \right) = \nabla_1^2 \phi \quad (8)$$

Imposing the condition [9]

$$\nabla_1^2 w + a^2 w = 0, \quad (9)$$

then

$$\phi = -\frac{1}{a^2} \frac{\partial w}{\partial z} + \phi', \quad (10)$$

where ϕ' denotes a plane-harmonic function of x and y .

At the cylindrical boundary, along a plane of symmetry, u and v must satisfy the condition

$$0 = u \cos(x, n) + v \cos(y, n),$$

$$= -\frac{\partial \phi}{\partial n} - \frac{\partial \psi}{\partial s} \quad \text{according to eq. (6)} \quad (11)$$

For steady state, from equation (7), one obtains

$$\nabla^2 \nabla_1^2 \psi = 0 \quad (12)$$

If μ is constant and if $\partial \psi / \partial n$ vanishes at every point in the boundary; and when $\partial w / \partial n = 0$ at the boundary, according to equation (10), one obtains ϕ' is constant. Then from equations (6), (8) and (10), one has

$$u = \frac{1}{a^2} \frac{\partial^2 w}{\partial x \partial z}, \quad \text{and} \quad v = \frac{1}{a^2} \frac{\partial^2 w}{\partial y \partial z} \quad (13)$$

The solution for the hexagonal pattern was found by Christopherson [8]. The solution is

$$w = \frac{1}{3} w^+(z) \left\{ 2 \cos \frac{2\pi x}{L\sqrt{3}} \cos \frac{2\pi y}{3L} + \cos \frac{4\pi y}{3L} \right\}, \quad (14)$$

where L measures the sides of the hexagon.

An alternative form of the solution is

$$w = \frac{1}{3} w^+(z) \left(\cos \frac{4\pi}{3L} \left(\frac{\sqrt{3}}{2} x + \frac{1}{2} y \right) + \cos \frac{4\pi}{3L} \left(-\frac{\sqrt{3}}{2} x - \frac{1}{2} y \right) + \cos \frac{4\pi y}{3L} \right) \quad (15)$$

One notes that $x = 0$ and $y = 0$ represent the plane of symmetry, and the motion is two-dimensional. Thus for $x = 0$, one obtains

$$u = \frac{\partial}{\partial x} \frac{\partial^2 w}{\partial x \partial z} = 0 \quad (16)$$

$$v = \frac{1}{a} \frac{\partial^2 w}{\partial y \partial z} = -\frac{Dw^+}{3a} \frac{4}{3L} (b + 2 \cos \frac{2\pi y}{3L}) \sin \frac{2\pi y}{3L} \quad (17)$$

$$w_0 = \frac{1}{3} w^+ \left(2 \cos \frac{2\pi y}{3L} + \cos \frac{4\pi y}{3L} \right) \quad (18)$$

The equation, $dy/v = dz/w$, gives the streamlines in the (y, z) -plane and can be readily integrated by using equations (17) and (18) to give

$$\left\{ \frac{1 + 2 \cos\left(\frac{2\pi y}{3L}\right)}{1 + \cos\left(\frac{2\pi y}{3L}\right)} \sin \frac{2\pi y}{3L} \right\}^2 \frac{w^+(z)}{w_{\max}^+} = \text{constant} = \psi_v \quad (19)$$

Similarly, for $y = 0$, one obtains

$$u = \frac{1}{a^2} \frac{\partial^2 w}{\partial x \partial z} = - \frac{Dw^+}{3a^2} \frac{4\pi}{L\sqrt{3}} \sin \frac{2\pi x}{L\sqrt{3}} \quad (20)$$

$$v = 0 \quad (21)$$

$$w = \frac{1}{3} w^+ (2 \cos \frac{2\pi x}{L\sqrt{3}} + 1), \quad (22)$$

and the equation for the streamlines in the (x, z) -plane is $dx/u = dz/w$, which gives

$$\left\{ (1 - \cos \frac{2\pi x}{L\sqrt{3}}) \sin \frac{2\pi x}{L\sqrt{3}} \right\}^{2/3} \frac{w^+(z)}{w_{\max}^+} = \text{constant} = \psi_u \quad (23)$$

The streamlines of the secondary flow from equations (19) and (23) are plotted in Figs. (11a) and (11b) of Chapter VIII.
