## PERMISSION TO MICROFILM — AUTORISATION DE MICROFILMER

- Please print or type — Écrire en lettres moulées ou dactylographier

Full Name of Author — Nom complet de l'auteur

MBANE FO MBONU EKWENCHI

Date of Birth — Date de naissance

25<sup>th</sup> FEB 1943

Country of Birth — Lieu de naissance

NIGERIA

Permanent Address — Résidence fixe

215 L. MICHENER PARK, EDMONTON, ALBERTA

Title of Thesis — Titre de la thèse

HYDROGEN ATOM REACTIONS WITH ORGANOSULFUR  
COMPOUNDS

University — Université

UNIVERSITY OF ALBERTA, EDMONTON, ALBERTA

Degree for which thesis was presented — Grade pour lequel cette thèse fut présentée

Ph. D. IN CHEMISTRY

Year this degree conferred — Année d'obtention de ce grade

1980

Name of Supervisor — Nom du directeur de thèse

DR. STRAUSZ

Permission is hereby granted to the NATIONAL LIBRARY OF CANADA to microfilm this thesis and to lend or sell copies of the film.

The author reserves other publication rights, and neither the thesis nor extensive extracts from it may be printed or otherwise reproduced without the author's written permission.

L'autorisation est, par la présente, accordée à la BIBLIOTHÈQUE NATIONALE DU CANADA de microfilmer cette thèse et de prêter ou de vendre des exemplaires du film.

L'auteur se réserve les autres droits de publication; ni la thèse ni de longs extraits de celle-ci ne doivent être imprimés ou autrement reproduits sans l'autorisation écrite de l'auteur.

Date

September 12, 1980

Signature

## NOTICE

The quality of this microfiche is heavily dependent upon the quality of the original thesis submitted for microfilming. Every effort has been made to ensure the highest quality of reproduction possible.

If pages are missing, contact the university which granted the degree.

Some pages may have indistinct print especially if the original pages were typed with a poor typewriter ribbon or if the university sent us a poor photocopy.

Previously copyrighted materials (journal articles, published tests, etc.) are not filmed.

Reproduction in full or in part of this film is governed by the Canadian Copyright Act, R.S.C. 1970, c. C-30. Please read the authorization forms which accompany this thesis.

THIS DISSERTATION  
HAS BEEN MICROFILMED  
EXACTLY AS RECEIVED

Ottawa, Canada  
K1A 0N4

## AVIS

La qualité de cette microfiche dépend grandement de la qualité de la thèse soumise au microfilmage. Nous avons tout fait pour assurer une qualité supérieure de reproduction.

S'il manque des pages, veuillez communiquer avec l'université qui a conféré le grade.

La qualité d'impression de certaines pages peut laisser à désirer, surtout si les pages originales ont été dactylographiées à l'aide d'un ruban usé ou si l'université nous a fait parvenir une photocopie de mauvaise qualité.

Les documents qui font déjà l'objet d'un droit d'auteur (articles de revue, examens publiés, etc.) ne sont pas microfilmés.

La reproduction, même partielle, de ce microfilm est soumise à la Loi canadienne sur le droit d'auteur, SRC 1970, c. C-30. Veuillez prendre connaissance des formules d'autorisation qui accompagnent cette thèse.

## ABSTRACT

The reactions of hydrogen atoms, generated by the  $Hg(^3P_1)$  photosensitization of  $H_2$ , with dimethyldisulfide, diethyldisulfide, ethylmethyldisulfide, bis(trifluoromethyl)disulfide and diethylsulfide, have been investigated in detail. With the exception of the fluorinated disulfide from which no retrievable products could be detected, the sole primary products are the corresponding thiols, formed in quantum yields ranging from 2.1 to 2.32 at room temperature. From the effects of exposure time, substrate pressure, light intensity, temperature and added gases, it is concluded that the sole primary reaction is attack by the H atom on the non-bonding orbitals of sulfur, e.g.,

For the  $H + CF_3SSCF_3$  reaction polymerization is the observable reaction but experiments carried out in the presence of ethylene conclusively demonstrated that  $CF_3$  radicals were present. It is believed that the expected primary product,  $CF_3SH$ , reacts with the substrate  $CF_3SSCF_3$  to form some unidentified product(s).

Secondary reactions of the thiyl radicals generated in the primary step consist of combination and disproportionation, metathetical displacement, i.e.,  $\text{RS} + \text{RSSR}' \rightarrow \text{RSSR} + \text{R}'\text{S}$ , and, for the case of  $\text{C}_2\text{H}_5\text{S}$  radicals, abstraction from the substrate:  $\text{C}_2\text{H}_5\text{S} + \text{C}_2\text{H}_5\text{SSC}_2\text{H}_5 \rightarrow \text{C}_2\text{H}_5\text{SH} + \text{C}_2\text{H}_4\text{SSC}_2\text{H}_5$ . The latter reaction is relatively efficient, the estimated activation energy being only  $3.6 \text{ kcal mol}^{-1}$ .

$\text{C}_2\text{H}_5$  radicals were shown to abstract hydrogen from  $\text{C}_2\text{H}_5\text{SC}_2\text{H}_5$  and the relatively low activation energy for this reaction,  $\sim 6.9 \text{ kcal mol}^{-1}$ , as compared to abstraction from alkanes, points to a low methylenic C-H bond strength in this molecule.

The  $\text{H} + \text{CH}_3\text{SSC}_2\text{H}_5$  system is complex owing to the occurrence of a chain sequence involving metathetical reactions of  $\text{C}_2\text{H}_5\text{S}$  and  $\text{CH}_3\text{S}$  radicals. The quantum yields of the symmetrical disulfides thus produced are initially very high, ~92, and decrease with increasing exposure time to a steady state value. Computer modeling of a reaction sequence consisting of fifteen elementary steps adequately reproduces the experimentally observed trends.

Rate parameters for the  $\text{H} + \text{CH}_3\text{SSCH}_3$ ,  $\text{C}_2\text{H}_5\text{SSC}_2\text{H}_5$  and  $\text{C}_2\text{H}_5\text{SC}_2\text{H}_5$  reactions were determined in competition with the  $\text{H} + \text{C}_2\text{H}_4$  reaction and, for the  $\text{H} + \text{CF}_3\text{SSCF}_3$  case, in competition with the  $\text{H} + \text{S}$  reaction. The activation energies are all low ranging from 0.1 to  $4.5 \text{ kcal mol}^{-1}$  in this sequence, and were shown to be directly

related to the overall exothermicities of the primary reaction.

On this basis, the activation energy for the  $\text{H} + \text{CH}_3\text{SSC}_2\text{H}_5$  reaction is estimated to be  $0.9 < E_a < 1.4 \text{ kcal mol}^{-1}$ . The A factors are in the  $10^{12}-10^{13}$  range and the experimental entropies of activation can be reproduced theoretically on the basis of a rigid transition state featuring H atom attack on the sulfur 3p orbitals.

## ACKNOWLEDGMENTS

The author wishes to express his sincere appreciation and gratitude to Professor O. P. Strausz for his supervision, guidance, support and encouragement throughout the course of this study.

My special thanks go to the members of the Photo-chemistry group, particularly to Dr. I. Safarik whose help was invaluable in the interpretation of the results, Dr. T. Yokota for many interesting and helpful discussions, Mr. A. Clement, Drs. F.C. James, R.K. Gosavi, M. Torres, H. Murai, and J.W. Bottemheim for instructional assistance.

I am especially grateful to Mr. A. Jodhan for his encouragement and invaluable technical assistance.

The author wishes to thank Dr. E. M. Lown for careful reading and assistance with the preparation of the manuscript and Mrs. Jacki Jorgensen for her conscientious efforts in typing this thesis.

The invaluable assistance of the entire technical and administrative staff of the Chemistry Department is also appreciated.

The author wishes to express his profound gratitude to his wife, Uzo, whose devotion and unceasing cooperation have made this work possible.

I am grateful to Professor C. O. Okafor for kindling my interest in academic research and to Dr. M. O. Eze for

continued interest and encouragement during the course of  
this study.

Finally, the financial assistance of the University of  
Alberta and the Federal Scholarship Board, Nigeria is  
gratefully acknowledged.

## CHAPTER I

### INTRODUCTION

Knowledge concerning the mechanism of the reactions of atoms and radicals with the sulfur moiety of alkyl disulfides and sulfides has many practical implications. For example, it might aid in interpreting some of the complex kinetic behaviour of certain biological systems since disulfide and sulfide bridges occur frequently in the structures of many proteins and enzymes; these are primarily responsible for maintaining the tertiary structure of many proteins.<sup>1,2</sup> The sulfur atoms in these compounds are very susceptible to radical attack, and radiation damage to enzymes and other protein material could occur via attack on the disulfide moiety. Studies on hydrogen atom reactions with disulfides and sulfides are also of particular significance to the petroleum industry,<sup>3-5</sup> where hydrodesulfurization constitutes a major process in the upgrading of crudes. In particular, the sulfur content of Alberta oil sand bitumens is unusually high, of the order of ~5%, and this creates serious problems in catalyst poisoning and removal of volatile sulfur-containing components from the effluent gases. Another area of practical importance is the polymer industry, where disulfides have been shown to be effective polymerization initiators.<sup>6,7</sup>

Before reviewing recent developments in atomic and radical reactions with disulfides and sulfides, let us turn our attention to the physical and chemical properties of sulfides and disulfides.

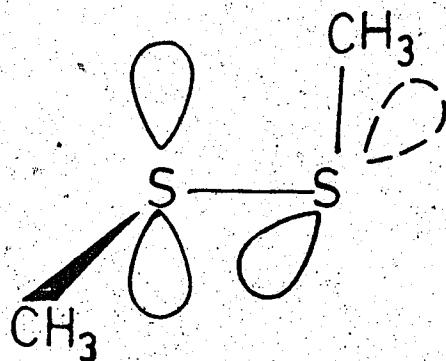

### 1. Physical and Chemical Properties of Disulfides and Sulfides

#### (a) Disulfides

##### (i) Molecular Parameters of Disulfides

The S-S bond in disulfides is appreciably stronger ( $\sim 67\text{-}74 \text{ kcal mol}^{-1}$ ) than the O-O bond in peroxides ( $\sim 40\text{-}45 \text{ kcal mol}^{-1}$ ) and this accounts, in part, for the greater relative stability of disulfides, RSSR, compared to ROOR compounds. The covalent radius of the sulfur atom is also appreciably larger than that of the oxygen or carbon atom; the bond lengths<sup>8</sup> are, C-C 1.53 Å, C-O 1.45 Å, and C-S 1.82 Å. Similarly, disulfide bond lengths ( $d(\text{S-S}) \sim 2.0\text{-}2.1 \text{ Å}$ ) are about 0.5-0.6 Å greater than those of C-O or C-C bonds. Hence steric accessibility of the S-S moiety to reagent attack should be quite favourable, and this is indeed observed experimentally.<sup>9</sup> Furthermore, sulfur can accommodate more than eight outer valence electrons via valence shell expansion involving d orbitals; however, the possible consequences with regard to the reactivity of disulfides is not well established.

Organic disulfides, RSSR, have, in general, a geometry corresponding to that of  $\text{CH}_3\text{SSCH}_3$ . It has been shown by electron diffraction<sup>10</sup> and microwave spectroscopy<sup>11</sup> that  $\text{CH}_3\text{SSCH}_3$  has the structure shown below:

The molecular orbitals filled by the valence electrons in C-S-S-C skeleton are constructed mainly from the atomic orbitals,  $3s$ ,  $3p_x$ ,  $3p_y$ ,  $3p_z$ , and  $sp^3$  orbital of C atom. Various MO calculations consistently predict the two highest occupied molecular orbitals to be of lone-pair character formed largely by out-of-plane 3p atomic orbitals on each sulfur, i.e., n (p type).<sup>12,15</sup> Due to the appreciable size of these orbitals in the S-S moiety, the pairs of the non-bonded electrons on the adjacent atoms are considered to repel one another so that in order to minimize this repulsion, the  $\text{CH}_3$  groups of  $\text{CH}_3\text{SSCH}_3$  assume a dihedral angle  $\sim 90^\circ$ . The molecular parameters found for  $\text{CH}_3\text{SSCH}_3$ <sup>12</sup> are as follows:  $d(\text{S-S}) = 2.03 \text{ \AA}$ ,  $d(\text{C-S}) = 1.81 \text{ \AA}$ ,  $d(\text{C-H}) = 1.10 \text{ \AA}$ ,  $\alpha(\text{CSS}) = 103^\circ$ , and  $\tau(\text{dihedral angle}) = 84^\circ$ . In general, alkyl disulfides have  $d(\text{S-S})$ ,  $\alpha$  and  $\tau$  values which are dependent on the nature of R. The barrier to

rotation around the S-S bond has been claimed to vary from 2.7 kcal mol<sup>-1</sup> ( $\text{H}_2\text{S}_2$ ) to 14.2 kcal mol<sup>-1</sup> ( $\text{S}_2\text{Cl}_2$ ),<sup>13</sup> the values for  $\text{CH}_3\text{SSCH}_3$  and  $\text{C}_2\text{H}_5\text{SSC}_2\text{H}_5$  being 9.5 and 13.2 kcal mol<sup>-1</sup> respectively.<sup>14</sup>

### (ii) Structural Conformations of Disulfides

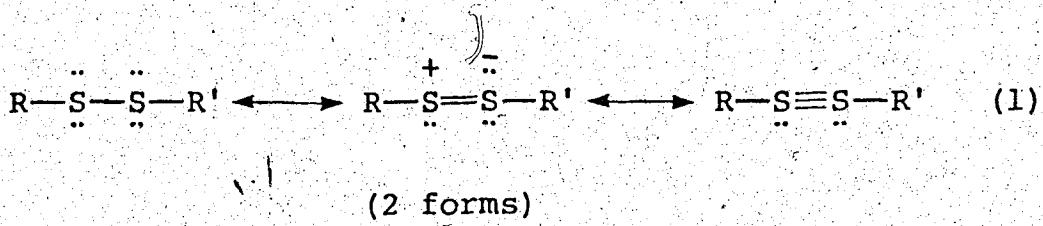

Considerable attention has been devoted recently to the structures and conformational preferences of simple alkyl disulfides.<sup>15,16</sup>  $\text{CH}_3\text{SSCH}_3$  has been assumed to exist only in one conformation, the gauche conformer. However, results from a gas phase electron diffraction study<sup>15</sup> indicate that  $\text{CH}_3\text{SSC}_2\text{H}_5$  exists as a mixture of at least two conformations. From Raman spectral studies<sup>16</sup> on  $\text{CH}_3\text{SSC}_2\text{H}_5$  and  $\text{C}_2\text{H}_5\text{SSC}_2\text{H}_5$ , the variation in the positions and intensities of the fundamentals in the spectra of these compounds as a function of temperature from ~77 to 320°K are claimed to be consistent with the presence of three rotational isomers, differing in their conformations about their C-S bonds. In  $\text{C}_2\text{H}_5\text{SSC}_2\text{H}_5$ , the gauche-gauche conformation is apparently the most stable of the three rotamers in the gas phase.

### (iii) Spectral Properties of Disulfides

The UV spectra of most aliphatic disulfides show a rather broad maximum at ~250 nm which is associated with an electronic transition from the non-bonding n orbital (p type) to the antibonding  $\sigma^*$  orbitals. The absorption

maximum was shown to be displaced to progressively shorter wavelengths in the series  $(CH_3)_2S_2$  ( $\lambda_{max} = 254.5 \text{ nm}$ ),  $(C_2H_5)_2S_2$  ( $\lambda_{max} = 251.5 \text{ nm}$ ) and  $(i-C_3H_7)_2S_2$  ( $\lambda_{max} = 245.0 \text{ nm}$ ).<sup>17</sup> MO calculations on various disulfide-bond containing molecules have shown that, in general, the further the dihedral angle from  $90^\circ$ , the more red shifted the lowest energy transition.<sup>17</sup>

In the PE spectra of organic disulfides<sup>18</sup> a splitting of the first band is observed, corresponding to ionization from one of the  $3p_\pi$  orbitals. These two molecular orbitals thus formed are always the highest occupied orbitals in the molecule. Since the first band in the spectrum of RSR is always unsplit, the cause of the splitting in RSSR species has been attributed to  $p_\pi-p_\pi$  interactions whereby the 3d orbitals of the sulfur atom give rise to  $pd_\pi$  bonds:<sup>19</sup>

#### (iv) Reactions of Disulfides

The chemistry of disulfides has been extensively investigated,<sup>20</sup> with the main emphasis on redox reactions, bimolecular reactions and thermal exchange reactions.

Simple disulfides can be reduced easily and completely to thiols.<sup>21</sup> Oxidation of disulfides leads ultimately to sulfonic acids, and several of the intermediates, namely, sulfenic and sulfinic acids or thiosulfinate, thiosulfonates, sulfinylsulfones and  $\alpha$ -disulfones, frequently can be isolated.<sup>22</sup>

Homolytic scission of disulfides readily takes place in thermolysis, photolysis, and also in electrochemical and other reactions<sup>23</sup> and can be unimolecular, arising from S-S cleavage,

or bimolecular, for example as a result of thiyl radical attack:

The resulting chain is long enough that this system has found practical application in the synthesis of unsymmetrical disulfides,<sup>24</sup> e.g.,

C-S cleavage is relatively unimportant in thermolysis and photolysis.<sup>25</sup>

Disulfides also undergo heterolytic scission of the S-S bond in the presence of nucleophiles or electrophiles and these reactions are now fairly well understood.<sup>6,7</sup>

Some of the more important reactions of disulfides are summarized in Table I.

(b) Sulfides

(i) Molecular Parameters of Sulfides

C-S bonds ( $70\text{-}72 \text{ kcal mol}^{-1}$ ) are weaker than C-O bonds ( $79\text{-}80 \text{ kcal mol}^{-1}$ ) and for both cases the bond strengths are little affected by simple alkyl groups.

C-S and C-O bond lengths for simple alkyl sulfides and ethers are generally close to  $1.82 \text{ \AA}$  (C-S) and  $1.41 \text{ \AA}$  (C-O).<sup>26</sup>

The corresponding bond angles,  $\angle \text{C-S-C}$  and  $\angle \text{C-O-C}$ , are around  $105^\circ$  and  $112^\circ$  respectively. In general, substitution of oxygen by sulfur leads to much longer bond lengths and somewhat smaller bond angles.

(ii) Spectral Properties

The spectra of simple dialkyl sulfides show strong bands in the region  $200\text{-}215 \text{ nm}$  and a weak continuum having a maximum near  $230 \text{ nm}$ . The former bands are thought to be due to a  $\sigma\text{-}\sigma^*$  transition in the C-S bond and the latter to an  $n_p\text{-}\sigma^*$  transition involving the unshared

electrons of sulfur.<sup>26</sup> MO calculations predict that the lowest energy transition in sulfides should be largely  $4s_S$  in character while the next three degenerate transitions should be primarily  $3d_S$ . The calculated transition energies were in good agreement with experimentally observed values.<sup>27</sup>

TABLE I  
Some Reactions of Disulfides and Sulfides

Type of Reaction	Disulfides	Sulfides
1. Photolytic or thermal S-S or C-S scission	$RSSR \xrightarrow{h\nu \text{ or } \Delta} 2RS$	$RSR \xrightarrow{h\nu \text{ or } \Delta} RS + R$
2. Catalytic scission of the S-S bond	$Fe^{2+} + RSSR \xrightarrow{h\nu \text{ or } \Delta} RS^- + RS \cdot + Fe^{3+}$	
3. Electrophilic Reaction	$RSSR + H^+ \rightarrow RSH + RS^+$	
4. Nucleophilic Reaction	$RSSR + 2NaH \xrightarrow{aq} 2RSH + 2NaOH$	
5. Oxidation	$RSSR \xrightarrow{[O]} RSSR \overset{O}{\underset{  }{\text{O}}} \text{ etc.}$	$RSR \xrightarrow{[O]} RSR \overset{O}{\underset{  }{\text{O}}} \text{ etc.}$
6. Reduction	$RSSR \xrightarrow{[H]} 2RSH$	$RSR \xrightarrow{[H]} RSH + RH$
7. Disproportionation	$R^1SSR^1 + R^2SSR^2 \rightarrow 2R^1SSR^2$	
8. Metathetical Displacement Reactions	$R^1 + RSSR \rightarrow RSR^1 + SR$	$R^1 + RSR^1 + R$
9. Hydrogen Abstraction	$RS + RSSR \rightarrow RSH + RSSR(-H)$	$R^1 + RSR \rightarrow R^1H + RSSR(-H)$

### (iii) Structural Conformations of Sulfides

The molecular vibrations of alkyl sulfides have been extensively studied.<sup>28</sup>  $\text{CH}_3\text{SCH}_3$  has a  $C_{2v}$  molecular symmetry while Scott *et al.* postulated three possible conformations,  $C_{2v}$  (TT),  $C_1$  (TG) and  $C_2$  (GG) for  $\text{C}_2\text{H}_5\text{SC}_2\text{H}_5$ . Only two conformers however,  $C_{2v}$  and  $C_1$ , appear to be stable since the  $C_2$  conformation was not observed in the spectrum.<sup>28b</sup>

MO calculations on organic sulfides suggest that the contribution of 3d orbitals to the charge distribution is important, but that to the stable conformation and rotational barrier is very small. The shape and energy of the lowest unoccupied molecular orbital are particularly sensitive to the participation of 3d orbitals.<sup>29</sup>

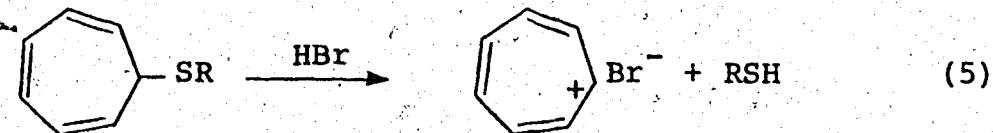

### (iv) Reactions of Sulfides

It is well known that the nucleophilicity of the lone pairs of electrons of the sulfur atom is larger than that of oxygen. However, the basicity of the sulfur atom is smaller than that of oxygen. Consequently, sulfur compounds exhibit chemical properties different from those of their oxygen counterparts. In most reactions involving sulfides, it is commonly assumed that the site of attack must be at the sulfur atom. There are several reasons for this;<sup>30</sup> (1) sulfur is more electropositive and polarizable than carbon; (2) the electronegativity of

the sulfur atom is much less than that of oxygen; and

(3) sulfur can utilise its 3d orbitals in chemical bonding.

Reactions of sulfides may be divided into (1) those taking place directly on the sulfur atom, (2) those occurring at another part of the molecule, and (3) those occurring by C-S cleavage. The sulfur atom in aliphatic sulfides is generally stable towards nucleophilic reagents but an electrophilic reagent promotes C-S cleavage, for example,<sup>31</sup>

Cleavage of the C-S bond of sulfides is also known to occur in thermal and photochemical reactions,

and the free radicals thus generated react with the sulfides exclusively by metathetical radical displacement.

The most common reactions of sulfides are summarized in Table I.

Some thermodynamic properties of sulfides and disulfides are summarized in Table II, along with those of other species pertinent to this study.

## 2. Atomic and Radical Reactions with Sulfides and Disulfides.

### (a) H Atom Reactions With Sulfides

For kinetic studies in the gas phase, the most commonly employed sources of hydrogen atoms are microwave discharge of  $H_2$ ,<sup>33</sup>  $Hg$  ( $^3P_1$ ) sensitized decomposition of  $H_2$ <sup>34</sup> and the photolysis of  $H_2S$ .<sup>35</sup> In the latter case H atoms are initially produced with a substantial amount of excess kinetic energy and consequently high pressures of a moderator gas are required for thermalization. A less commonly used but viable source of H atoms is the photolysis of alkanethiols.<sup>36</sup>

With  $COS$ <sup>37</sup> and thiirane<sup>38</sup> efficient desulfurization was shown to take place,

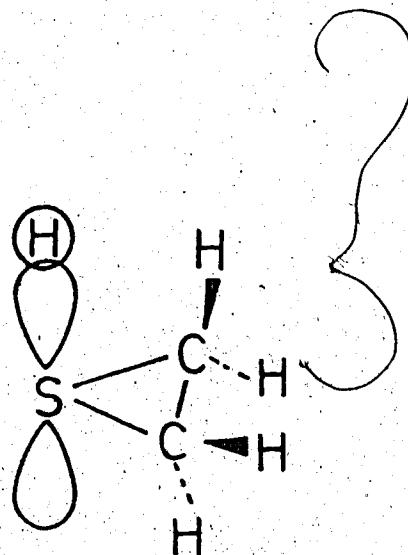

and the corresponding rate constants, derived from competitive experiments, are

$$k_8 = (9.1 \pm 1.2) \times 10^{12} \exp [(-3900 \pm 370)/RT] \text{cm}^3 \text{mol}^{-1} \text{s}^{-1}$$

$$k_9 = (5.7 \pm 0.7) \times 10^{13} \exp [(-1944 \pm 175)/RT] \text{cm}^3 \text{mol}^{-1} \text{s}^{-1}$$

On the basis of absolute rate theory calculations it was concluded that the initial interaction involves the non-bonding 3p orbital of the S atom, e.g.,

It should be noted that the analogous hypothetical deoxygenation reaction with oxirane has not been observed; instead, hydrogen atoms react with oxirane exclusively by hydrogen abstraction,<sup>39</sup>

and the rate constant is

$$k_{10} = (3.8 \pm 0.5) \times 10^{13} \exp [(-8500 \pm 200)/RT] \text{ cm}^3 \text{ mol}^{-1} \text{ s}^{-1}$$

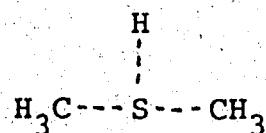

H atoms react with  $\text{CH}_3\text{SCH}_3$  to yield  $\text{CH}_3\text{SH}$  and  $\text{CH}_4$  as major products.<sup>40</sup> From the effects of exposure time, concentrations, and added gases it was concluded that the only primary reaction of importance is:

i.e., here again, attack takes place exclusively at the sulfur atom. Relative to the  $\text{H} + \text{H}_2\text{S}$  reaction, the rate parameters for step (11) were found to be:

$$k_{11} = (1.71 \pm 0.26) \times 10^{13} \exp[-(2612 \pm 88)/RT] \text{ cm}^3 \text{ mol}^{-1} \text{ s}^{-1}$$

It was also shown that the experimental entropy of activation, -24.6 e.u., could be reproduced theoretically if a symmetrical transition state,

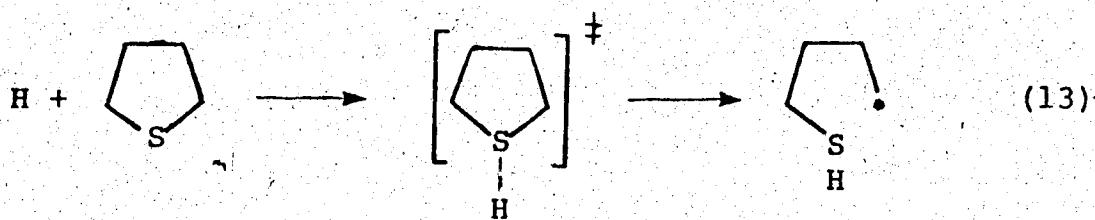

featuring H atom attack on sulfur was assumed. Since the source of H atoms in this study was the photolysis of  $\text{H}_2\text{S}$ , the overall mechanism is quite complex owing to the presence of HS radicals, e.g., it was shown that HS engages in a metathetical reaction with the substrate,

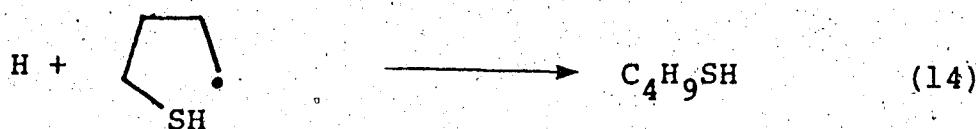

thereby initiating a short chain.

With thiolane, it is believed that the H atom adds to sulfur and the intermediate fragments via C-S cleavage:<sup>41</sup>

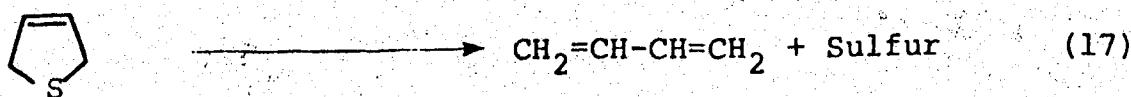

The resulting radical then combines with an H atom to form 1-butanethiol:

This system is in complete contrast to the  $\text{H} + \text{C}_2\text{H}_4\text{S}$  reaction where sulfur abstraction is the only observed process; the reason for this was ascribed<sup>41</sup> to differences in the stabilization of the products.

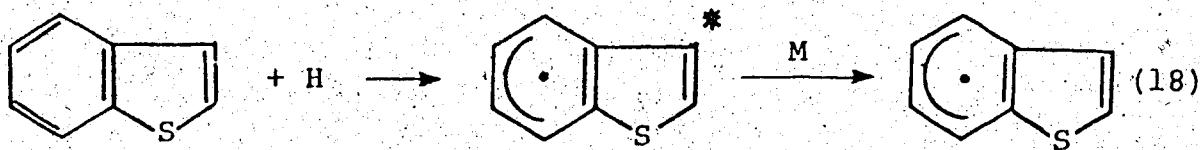

H atoms react with thiophene to yield 1,3-butadiene and elemental sulfur as major products.<sup>42</sup> Several minor products were also detected, including  $\text{H}_2\text{S}$  and  $\text{C}_1\text{-C}_4$  compounds. It was postulated that two H atoms add to the ring in succession, and that the resulting intermediate, 1,4-dihydrothiophene, decomposes to yield butadiene and sulfur:

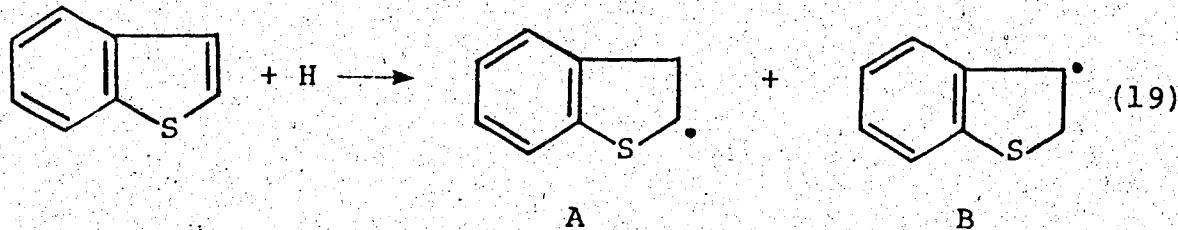

The detection of  $\text{H}_2\text{S}$  as one of the minor reaction products

suggests that attack could have also occurred at the sulfur atom but this reaction pathway is not very significant. In anycase, the overall mechanism is very complex and much more information would be needed on the nature of the intermediates before the various pathways can be fully elucidated.

The reaction of H atoms with benzothiophene was studied recently by Amano *et al.*<sup>43</sup> who postulated two primary processes. One involves H atom addition to the benzene ring and produces a vibrationally energized species which eventually is stabilized, giving rise to the formation of three isomers of dihydrobenzothiophene.

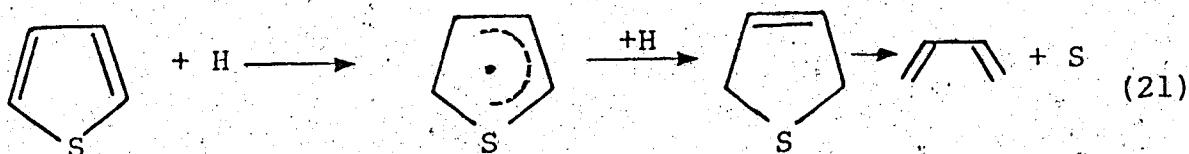

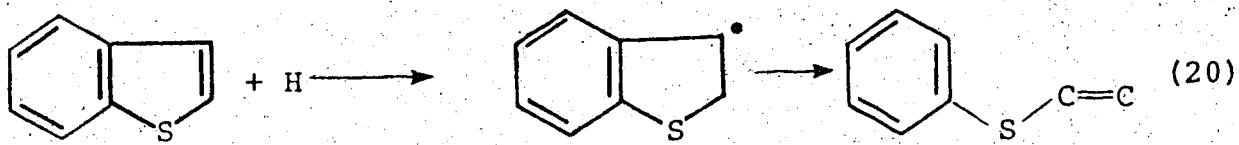

The other, more important pathway is addition to the thiophene ring, forming either the 1-thiaindan-2-yl (A) or 1-thiaindan-3-yl (B) radicals.

The identification of phenylvinylsulfide as a product, together with the absence of *o*-vinylbenzenethiol, indicates that the 3-position in benzothiophene is the preferred site of attack. This is in marked contrast with the case

of thiophene, where H atoms attack the 2-position.

### (b) $O(^3P)$ Atom Reactions

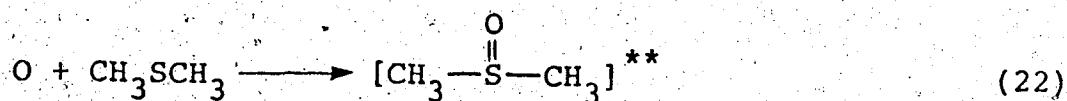

In contrast to the  $H +$  organosulfur systems, where the absence of  $H$  abstraction from the substrate had to be deduced from product analysis and kinetic considerations, the occurrence of  $H$  atom abstraction in  $O +$  organosulfur systems can be readily recognized. From the few studies reported to date however, no evidence has been reported to the effect that abstraction takes place and the results overwhelmingly point to S atom attack.

#### (i) With Sulfides

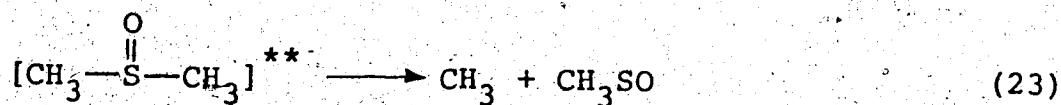

In gas phase kinetic studies, the most frequently employed sources of oxygen ( $^3P$ ) atoms are electrical and microwave discharge of  $O_2$ ,<sup>44,45</sup> photolysis ( $\lambda > 130$  nm) of  $O_2$ ,<sup>46</sup> and the  $Hg(^3P_1)$  sensitized decomposition of

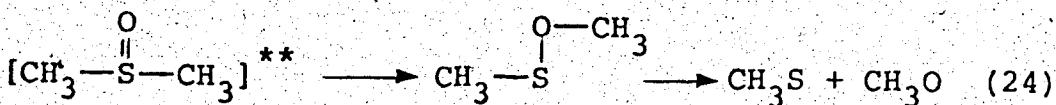

O atoms also appear to attack the S atom of  $\text{CH}_3\text{SCH}_3$  and the major products are  $\text{CH}_4$  and  $\text{CH}_3\text{SO}$ .<sup>45,48</sup> The excited adduct, postulated to be dimethylsulfoxide, contains about  $85-88 \text{ kcal mol}^{-1}$  excess internal energy.

This energy is about  $23 \text{ kcal mol}^{-1}$  in excess of that required for unimolecular decomposition via  $\text{S-CH}_3$  bond cleavage and therefore the excited adduct decomposes rapidly to  $\text{CH}_3$  and  $\text{CH}_3\text{SO}$ :

The minor products observed in this system, namely  $\text{CH}_3\text{S}$  and  $\text{CH}_3\text{O}$ , are probably formed as a result of rearrangement of the excited adduct followed by fragmentation, e.g.,

It was estimated however that rearrangement constitutes less than 1% of the decomposition. The rate constant for reaction (22) determined by the flash photolysis-resonance fluorescence method,<sup>48</sup> is:

$$k_{22} = (8.6 \pm 0.4) \times 10^{12} \exp[(727 \pm 31)/RT] \text{ cm}^3 \text{ mol}^{-1} \text{ s}^{-1}$$

and exhibited a negative temperature dependence. Thus the primary process in the  $O + CH_3SCH_3$  system is completely analogous to that of the  $H + CH_3SCH_3$  reaction, i.e., the attacking site is the S atom of the substrate. This result is however in complete contrast to the  $O + CH_3OCH_3$  reaction where it is believed that the initial reaction is hydrogen atom abstraction,<sup>49</sup>

With thiirane<sup>48</sup> efficient desulfurization takes place,

in complete analogy with the H and S atom reactions (*vide infra*) with this substrate. The rate constant for reaction (26), determined by the flash photolysis-resonance fluorescence method is

$$k_{26} = (8.1 \pm 0.5) \times 10^{12} \exp[-(35 \pm 40)/RT] \text{ cm}^3 \text{ mol}^{-1} \text{ s}^{-1}$$

With oxirane H atom abstraction is the only observable reaction<sup>50</sup>

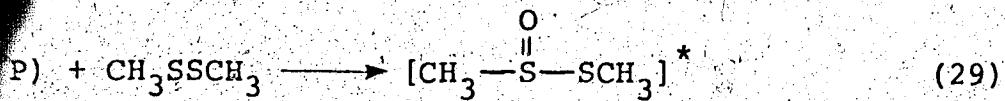

in spite of the fact that the direct formation of  $O_2 + C_2H_4$  is energetically more favourable.

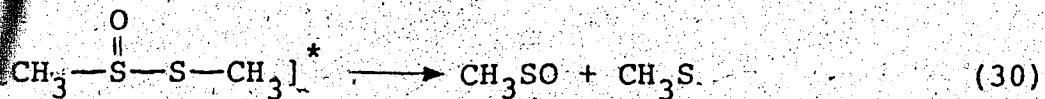

Bond energy-bond order calculations predict a prohibitively high activation energy for step (28), perhaps as a consequence of the somewhat lower exothermicity and the higher value of the higher value of the excitation energy of the  ${}^1\text{D}_2$  state of the oxygen than sulfur atom.

(ii) With Disulfides

The gas phase reaction of oxygen atoms with dimethyl-disulfide has been studied recently.<sup>48</sup> Although no stable products could be isolated, competitive experiments in the presence of  $\text{CH}_3\text{SH}$  showed that reaction does take place, as evidenced in the drastically reduced yields of  $\text{CH}_4$ ,  $\text{CH}_3\text{SO}$  and  $\text{CH}_3\text{SOH}$  from the  $\text{O} + \text{CH}_3\text{SH}$  reaction.<sup>51</sup> By analogy with the  $\text{O} + \text{CH}_3\text{SCH}_3$  reaction and on the basis of these considerations it was proposed that O atoms attack the S atom of the disulfide forming a vibrationally excited product,

which subsequently decomposes via S-S cleavage:

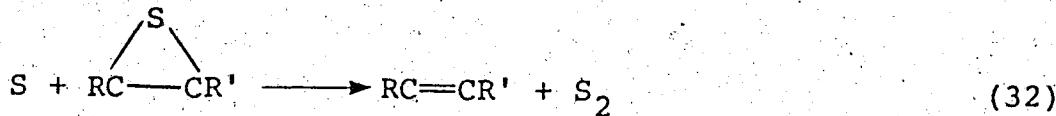

(c) Reactions of Ground State  $\text{S}({}^3\text{P})$  Atoms with Sulfides

S atoms have been shown to desulfurize  $\text{COS}$ ,<sup>45</sup>

$$k_{31} = 7.2 \times 10^{11} \text{ cm}^3 \text{ mol}^{-1} \text{ s}^{-1}, \text{ at } 25^\circ\text{C}$$

and thiranes<sup>52</sup> via a single step, concerted process:

The absolute rate constants, measured by the flash photolysis-kinetic spectroscopic technique,<sup>52</sup> at 25°C, are:

$$R = R' = H, k = 1.4 \times 10^{13} \text{ cm}^3 \text{ mol}^{-1} \text{ s}^{-1}$$

$$R = \text{CH}_3, R' = H, k = 2.7 \times 10^{13} \text{ cm}^3 \text{ mol}^{-1} \text{ s}^{-1}$$

$$R = R' = \text{CH}_3, k = 4.0 \times 10^{13} \text{ cm}^3 \text{ mol}^{-1} \text{ s}^{-1}$$

It has also been shown that  $E_a = 0$  for the  $\text{S} + \text{C}_2\text{H}_4\text{S}$  reaction.<sup>53</sup>

To date, the reactions of S atoms with alkyl sulfides and disulfides have not been reported.

#### (d) Reactions of Alkyl Radicals with Sulfides and Disulfides

Very few studies concerning radical reactions with organosulfur molecules have been reported to date.

##### (i) With Sulfides

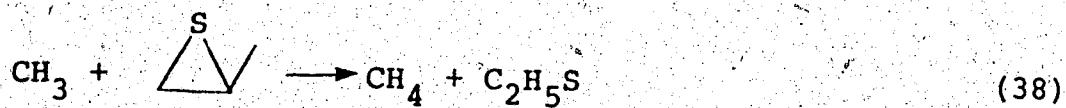

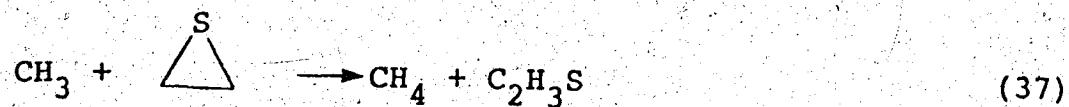

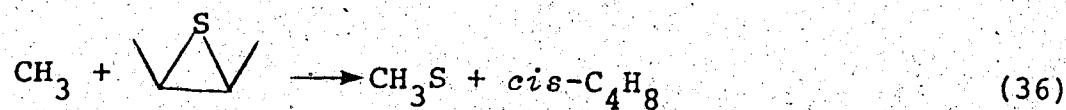

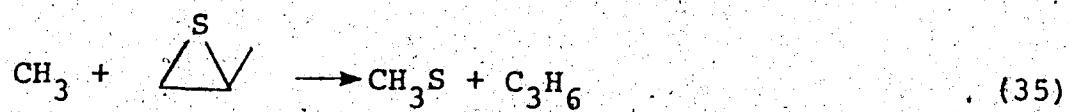

With COS, desulfurization by  $\text{CD}_3$  radicals takes place,<sup>54</sup>

and the rate constant, determined in competition with the  $2\text{CH}_3 + \text{C}_2\text{H}_6$  reaction is:

$$k_{33} = 3.8 \times 10^{11} \exp[-(11350)/RT] \text{ cm}^3 \text{ mol}^{-1} \text{ s}^{-1}$$

Methyl radicals react with thiirane, methylthiirane and *cis*-1,2-dimethylthiirane<sup>54,55</sup> via concerted desulfurization and, to a lesser extent, hydrogen abstraction:

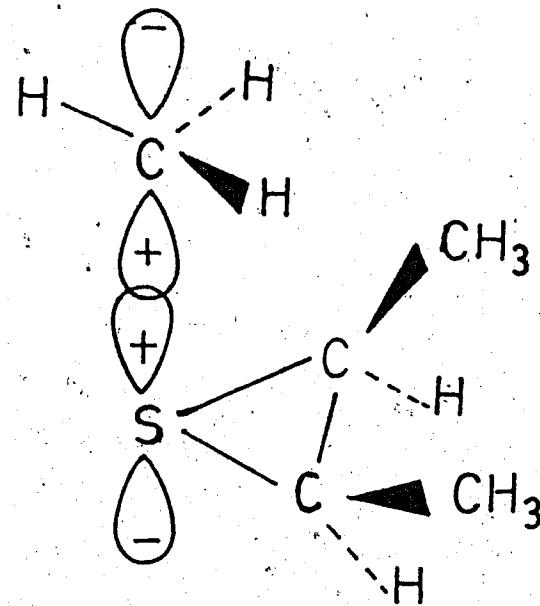

The corresponding Arrhenius parameters derived from kinetic analysis of the data are listed in Table III. Strausz and coworkers<sup>54</sup> suggested that the initial interaction involves the  $\pi$  orbital of the  $\text{CH}_3$  radical and the non-bonding 3p orbital of the S atom:

TABLE III  
Arrhenius Parameters for Some Atom Transfer Reactions

Compound	S-abstraction		H-abstraction	
	log A <sup>a</sup>	E <sub>a</sub> <sup>b</sup>	log A <sup>a</sup>	E <sub>a</sub> <sup>b</sup>
CH <sub>3</sub>				
S	11.35 ± 0.51 <sup>c</sup>	7.4 ± 0.9 <sup>c</sup>	11.34 ± 0.60 <sup>c</sup>	9.54 ± 1.00 <sup>c</sup>
S	11.33 ± 0.92 <sup>d</sup>	7.5 ± 1.7 <sup>d</sup>	11.00 ± 0.48 <sup>d</sup>	8.26 ± 0.87 <sup>d</sup>
S	12.31 ± 2.57 <sup>d</sup>	6.8 ± 3.9 <sup>d</sup>	11.03 ± 1.5 <sup>d</sup>	7.00 ± 2.41 <sup>d</sup>
COS	11.58 ± 0.25 <sup>c</sup>	11.4 ± 0.4 <sup>c</sup>		

<sup>a</sup>cm mol<sup>-1</sup> s<sup>-1</sup>; <sup>b</sup>kcal mol<sup>-1</sup>; <sup>c</sup>Ref. 54; <sup>d</sup>Ref. 55.

These results are in marked contrast to the  $\text{CH}_3 +$  epoxide systems,<sup>56</sup> where hydrogen abstraction is the only observable process in spite of the fact that the enthalpy changes for deoxygenation and desulfurization are not different. As noted above, however, BEBO calculations<sup>56</sup> predict a prohibitively high activation energy for deoxygenation by atoms and radicals. Moreover, the non-bonding 3p-orbital of S is more nucleophilic than the corresponding 2p orbital of O and sulfur has a higher aptitude for valence shell expansion; consequently, the activation energy for desulfurization is lowered.

Methyl radicals produced from the photolysis of  $\text{CH}_3\text{SCH}_3$  react with dimethylsulfide to yield methane via hydrogen abstraction:<sup>57</sup>

The activation energy for reaction (40) was reported by Rao and Knight<sup>57a</sup> to be  $9.30 \pm 0.50$  kcal mol<sup>-1</sup> and the rate constant, determined by Arthur and Lee<sup>57b</sup>, in competition with the  $2\text{CH}_3 \rightarrow \text{C}_2\text{H}_6$  reaction, is:

$$k_{40} = (4.17 \pm 0.84) \times 10^{11} \exp[-(9166 \pm 162)/RT] \text{cm}^3 \text{mol}^{-1} \text{s}^{-1}$$

Recently Arthur and Yeo<sup>58</sup> reported that trifluoromethyl radicals produced by the photolysis of hexafluoroacetone also react with  $\text{CH}_3\text{SCH}_3$  via hydrogen abstraction:

Surprisingly, the metathetical  $\text{CH}_3$  group displacement reaction,

was not detected. The rate constant for hydrogen abstraction by  $\text{CF}_3$  radicals is:

$$k_{42} = (4.76 \pm 1.00) \times 10^{11} \exp[-(6432 \pm 107)/RT] \text{cm}^3 \text{mol}^{-1} \text{s}^{-1}$$

Comparing the reactivities of  $\text{CH}_3$  and  $\text{CF}_3$  radicals with regard to hydrogen abstraction from  $\text{CH}_3\text{SCH}_3$  it is seen that at room temperature the rate of abstraction by  $\text{CF}_3$  is 51 times higher than that by  $\text{CH}_3$  and this difference is entirely due to the lower activation energy associated with the former reaction; this is in keeping with the general trend observed in the reactivities of  $\text{CH}_3$  and  $\text{CF}_3$ .

radicals with other compounds such as  $\text{CH}_3\text{OCH}_3$  and  $\text{CH}_3\text{COCH}_3$ .<sup>57</sup>

### (ii) With Disulfides

The photolysis of azomethane (at  $253.7 \ll \lambda < 315 \text{ nm}$ ) in the presence of dimethyldisulfide at  $100^\circ\text{C}$  leads to the formation of  $\text{CH}_4$  and  $\text{CH}_3\text{SCH}_3$ . From this, together with kinetic analysis of the data, Suama and Takezaki<sup>59</sup> concluded that methyl radicals undergo hydrogen abstraction with the substrate as well as  $\text{CH}_3\text{S}$  group displacement,

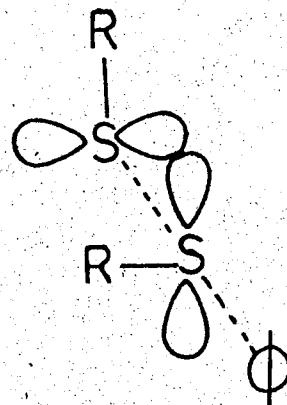

The relative rate constant ratio for reactions (43) and (44) is  $k_{43}/k_{44} = 3.4$ , and thus sulfur atom attack is again preferred over hydrogen abstraction.

### (e) Reactions of phenyl radicals with disulfides

Pryor and Guard<sup>9a</sup> studied the reactions of phenyl radicals, generated from phenylazotriphenylmethane, with aliphatic disulfides at  $60^\circ$ . Phenyl radicals undergo reactions analogous to those of alkyl radicals, i.e., hydrogen abstraction and thiyl radical displacement,

The relative importance of attack on the S atom of the disulfide decreased with increasing steric hindrance at the sulfur atom, as indicated by the 98% yield of  $C_6H_5SCH_3$  via attack on  $CH_3SSCH_3$  and the 49% yield of sulfide via attack on  $(t-C_4H_9)_2S_2$ . They proposed that the radical reaction involved a 3-atom-in-a-line Walden inversion type transition state

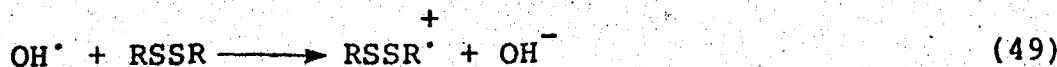

The relative rate constant ratio for reactions (47) and (48)

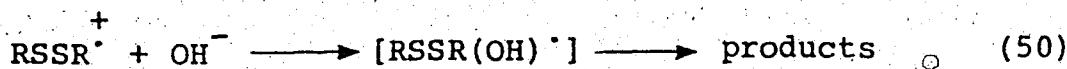

is  $k_{47}/k_{48} = 1.78$ .

#### (f) Reactions of Hydroxyl Radicals with Disulfides

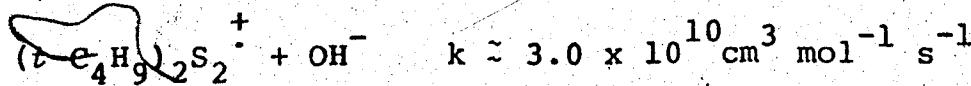

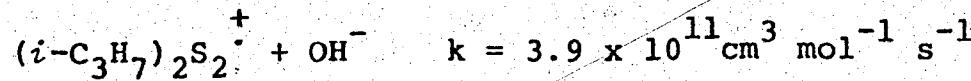

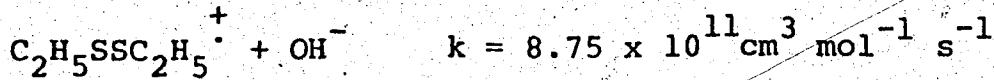

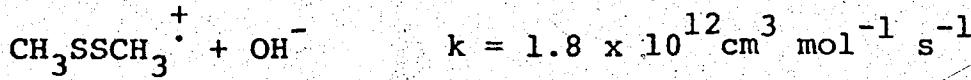

The interaction of hydroxyl radicals with simple aliphatic disulfides has been shown to lead to electron transfer,<sup>60</sup>

and the resulting radical cation decays by a diffusion-controlled bimolecular process:

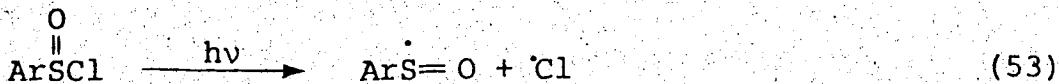

The rate constant for the neutralization of  $\text{RSSR}^{\cdot}$  by  $\text{OH}^-$  is controlled to a certain extent by the effective positive charge density at the sulfur bridge. Since the electron-donating properties of the substituents increase in the series  $\text{CH}_3 < \text{C}_2\text{H}_5 < (\text{CH}_3)_2\text{CH} < (\text{CH}_3)_3\text{C}$ , the net positive charge is expected to be highest for the  $(\text{CH}_3)_2\overset{+}{\text{S}}_2^{\cdot}$  and lowest for the  $(\text{CH}_3)_3\overset{+}{\text{C}}_2\overset{+}{\text{S}}_2^{\cdot}$  radical ions, and therefore the rate constants should follow that order. In addition, structural effects are considered to contribute to the observed changes in the rate constant for bimolecular decay since steric hindrance also increases, parallel to inductive effects. In agreement with these considerations the lowest value for the rate constant is found for the case of the  $(t\text{-Bu})_2\overset{+}{\text{S}}_2^{\cdot}$  radical ion. The observed rate constants are as follows:

When the reactions were monitored by esr spectroscopy new transient radical intermediates were observed, the signals of which were assigned to sulfinyl (ArSO or RSO) radicals.

A variety of these species have been detected and characterized. Further support for the assignment comes from the finding that radicals of the same type were detected during the low temperature photolysis of aromatic sulfinyl chlorides in diethyl ether.<sup>61</sup>

### 3. Thiyl Radicals.

#### (a) Generation, identification and physical properties

Thiyl radicals are commonly generated from the direct or mercury sensitized photolysis, or thermolysis, of thiols, sulfides and disulfides.<sup>62</sup> In the solid phase, they are readily apparent from their characteristic blue and red colours, and several reports have appeared on their spectral characteristics. Some representative examples are listed in Table IV.

TABLE IV  
Generation and Spectral Characteristics of Some Thiyl Radicals

Precursor	Method	Conditions	Thiyl Radical	$\lambda_{\text{max}}$ , nm	Ref.
$\text{CH}_3\text{SH}$	photolysis ( $\lambda = 254$ nm)	in cavities of a water clathrate lattice	$\text{CH}_3\text{S}^-$	310	65
$\text{C}_2\text{H}_5\text{SH}$	photolysis ( $\lambda = 254$ nm)	in cavities of a water clathrate lattice	$\text{C}_2\text{H}_5\text{S}^-$	370	65
RSH	photolysis ( $\lambda = 254$ nm)	rigid glass at 77°K	RS	~400	64a
RSSR	photolysis ( $\lambda = 254$ nm)	neat matrix at 77°K	RS	~360	64a
$\text{CH}_3\text{SH}$	flash photolysis ( $\lambda=195$ )	gas phase	$\text{CH}_3\text{S}^-$	219	67
$\text{CH}_3\text{SCH}_3$					
$\text{CH}_3\text{SSCH}_3$					

....continued

TABLE IV (continued)

$\phi_3$ CSH $\cdot$ CF <sub>3</sub> SSCF <sub>3</sub>	photolysis ( $\lambda=313$ )	benzene matrix at 77°K	$\phi_3$ CS	330	64b
	photolysis ( $\lambda=254$ nm)	neat matrix at 77°K	CF <sub>3</sub> S	-	63
		photolysis ( $\lambda=254$ nm)	CH <sub>2</sub> CH <sub>2</sub> CH <sub>2</sub> S	-	63

The thermal stability of thiyl radicals is relatively high.<sup>63-66</sup>  $\text{CH}_3\text{S}$  and  $\text{C}_2\text{H}_5\text{S}$  decay at temperatures where rotation about the C-S bond in the lattice is still restricted. Apparently heavier thiyl radicals are able to rotate to some extent before decaying, e.g., (*t*-butyl)S has a single line spectrum at ~130°K and decays at temperatures greater than 150°K. Radicals adsorbed on Vycor glass showed higher thermal stability, with rapid decay commencing only above 200°K. The observed increased thermal stability of the adsorbed radical is expected since adsorption decreases the mobility of the radical. It is this enhanced stability of adsorbed radicals which accounts for the characteristic decay rate differences between matrix and Vycor glass photolyses. Adsorption seems to prevent cage recombination of the geminate thiyl radical pair in disulfide photolyses and thus increases the apparent rate of photolysis. In the photolysis of mercaptans, cage recombination is unimportant because of the ease by which H atoms escape the cage.

The ESR spectra of various alkylthiyl radicals,<sup>63,64</sup>  $\text{CF}_3\text{S}$ ,  $\phi\text{S}$ ,  $\phi_3\text{CS}$ , ' $\text{CH}_2\text{CH}_2\text{CH}_2\text{S}'$ , and substituted  $\phi\text{S}$  have been obtained upon irradiation ( $\lambda < 220$  nm) of either neat solid disulfide matrices or of disulfides adsorbed on Vycor glass at 77°K. Simple alkylthiyl radicals have three g-values (generally referred to as the characteristic "sulfur pattern") about 2.058, 2.025, and 2.001.

The spectrum of  $\text{CF}_3\text{S}$  radicals is unusual in that it exhibits only two principal g-values (2.030 and 2.004), suggesting that the radical has axial symmetry. Arylthiyl radicals exhibit esr spectra similar to those of alkyl-thiyl radicals and only differ in the hyperfine structure; however, in the absence of  $\alpha$ -hydrogens which will couple with the electronic spin, three distinct anisotropic g values are obtained, indicating large spin-orbit coupling.

The unpaired spin is largely localized on the non-bonding orbital of the S atom. Para or electron-donating substituents stabilize ArS (presumably making ArS more like the stable species  $\text{ArS}^-$ , in contrast to the effect of electron withdrawing substituents which would make them more like the highly reactive species  $\text{RS}^+$ ).<sup>66</sup> In solution or gas phase, alkylthiyl radicals clearly exist as neutral free radicals. The gas phase characteristic UV absorption band for  $\text{CH}_3\text{S}$  radicals has been reported by Callear *et al.* as being 218.5 nm.<sup>67</sup>

#### (b) Reactions of Thiyl Radicals

Similarly to alkyl radicals, thiyl radicals undergo disproportionation, combination, abstraction, addition and metathetical reactions. Surprisingly, very little kinetic data are available but the results suggest that thiyl radicals are more reactive than alkyl radicals.

## (i) Disproportionation-Combination

Thiyl radicals, e.g., produced in the photolysis or thermolysis of thiols, alkylsulfides and disulfides disproportionate and combine according to the following equations:

and the rate constant ratio  $k_d/k_c$  can be calculated from the relative yields of thiol and disulfides. For the cases of  $\text{CH}_3\text{S}$  and  $\text{C}_2\text{H}_5\text{S}$  values of  $k_d/k_c \leq 0.05$  and 0.13, respectively, have been derived from the photolysis of  $\text{CH}_3\text{SCH}_3$ <sup>57a</sup> and Hg photosensitized decomposition of  $\text{C}_2\text{H}_5\text{SC}_2\text{H}_5$ .<sup>68</sup> The small values are another example in the growing body of evidence indicating that organosulfur compounds do not readily undergo transformations in which C-S bonds are converted to C=S, unlike the well established tendency of their oxygen analogs. This is a consequence of the relative exothermicities of the two processes. The generally smaller exothermicity of the  $\text{C-S} + \text{C-S} \rightarrow$  rearrangement results from the relatively small difference in the CS single and double bond strengths.

The rate constant for the combination of methylthiyl radical was determined in rotating sector experiments to be,  $k = (2.5 \pm 0.7) \times 10^{13} \text{ cm}^3 \text{ mol}^{-1} \text{ s}^{-1}$ .<sup>69</sup> This

value is, within experimental error, equal to the combination rate,  $k = (2.43 \pm 0.24) \times 10^{13} \text{ cm}^3 \text{ mol}^{-1} \text{ s}^{-1}$  reported for  $\text{CH}_3$  radicals.<sup>70</sup>

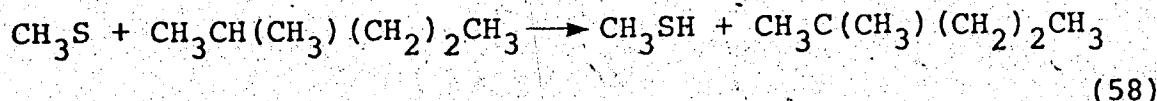

### (ii) Abstraction

$\text{CH}_3\text{SH}$  is a major product of the gas phase photolysis<sup>57,71</sup> (and thermolysis<sup>72</sup>) of  $\text{CH}_3\text{SCH}_3$  and  $\text{CH}_3\text{SSCH}_3$ , indicating that hydrogen abstraction takes place:

The measured activation energies for reactions (56) and (57) are  $5.4 \text{ kcal mol}^{-1}$  and  $5.1 \text{ kcal mol}^{-1}$ .

From competitive experiments with 2-methylpentane,

the activation energy for step (58) was estimated to be  $7.5 \text{ kcal mol}^{-1}$ .<sup>57a</sup>

Thus two conclusions emerge:

1. Alkylthiyl radicals are more reactive than alkyl radicals for which abstraction reactions from alkanes commonly feature activation energies ranging from 9 to  $12 \text{ kcal mol}^{-1}$ .
2. Alkylthiyl radicals abstract much more efficiently from sulfides and disulfides than from alkanes. This

would seem to suggest that the adjacent C-H bond in sulfides and disulfides are even weaker than a typical tertiary C-H bond in alkanes.

### (iii) Addition

The addition reactions of thiyl radicals to alkenes have not been extensively studied.<sup>69,73</sup> From the photolysis of CH<sub>3</sub>SH ( $\lambda = 254-265$  nm) in the presence of ethylene, the rate constant for

was determined to be  $4.8 \times 10^8 \text{ cm}^3 \text{ mol}^{-1} \text{ s}^{-1}$ .<sup>69</sup> The relative inefficiency of this reaction was also clearly demonstrated by Rao and Knight who showed that CH<sub>3</sub>S and C<sub>2</sub>H<sub>5</sub>S radicals produced in the photolysis of a mixture of 3 Torr dimethyldisulfide and 3 Torr diethyldisulfide could not be scavenged by 500 Torr C<sub>2</sub>H<sub>4</sub>.

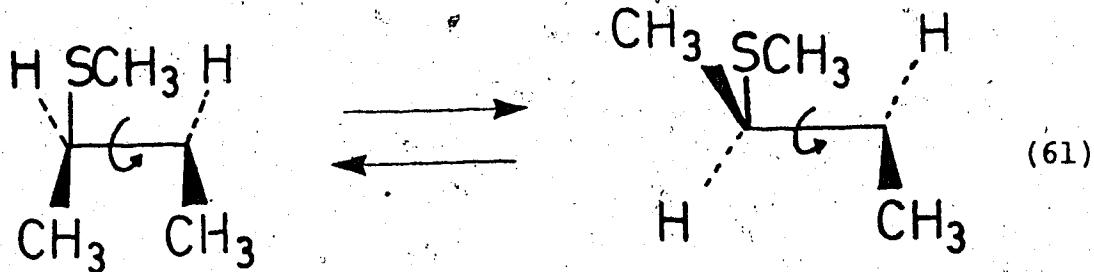

Comparison with methyl radical addition to ethylene however

for which  $k_{60} = 7.4 \times 10^5 \text{ cm}^3 \text{ mol}^{-1} \text{ s}^{-1}$ <sup>74</sup> again shows that CH<sub>3</sub>S is a better electrophile than CH<sub>3</sub>.

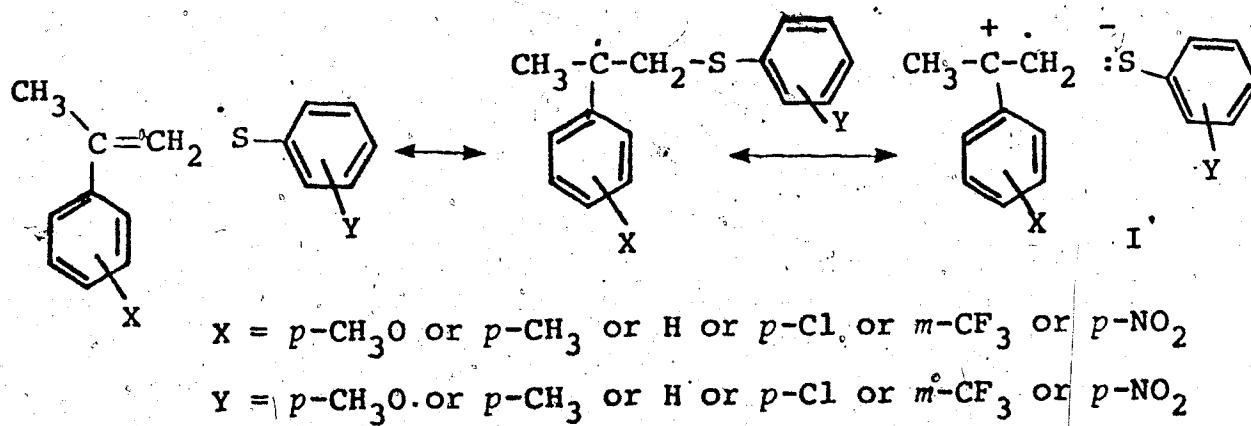

Walling and coworkers<sup>73a</sup> have shown that for the particular case of CH<sub>3</sub>S + *cis*-2-butene reaction (59) is reversible. Thus substantial amounts of *trans*-2-butene

were detected, indicating that rotation takes place in the adduct:

Decomposition of the adduct into  $\text{CH}_3\text{S}$  and 2-butene was very fast compared to hydrogen abstraction from  $\text{CH}_3\text{SH}$ , by a factor of 80 for the *trans*-2-butene adduct and 20 for the *cis*-butene adduct at  $60^\circ\text{C}$ .

In experiments involving the addition of substituted phenylthiyl radicals to substituted  $\alpha$ -methylstyrene, Geers *et al.*<sup>73b</sup> suggested that the addition reactions in such systems might, in general, be controlled by ground state and transition state electronic effects:

The ground state effects arise from (i) the presence of a strong electron-withdrawing group in the aromatic

portion of the alkene which tends to minimize the electron density at the reactive double bond, and (ii) the electrophilic character of the phenylthiyl radicals.

The transition state electronic effect comes from the fact that particular alkenes are able to assume a charge separated canonical structure I. Such a contributing form is most compatible when the anionic portion of the system is also electronically stabilized.

#### (iv) Metathetical Reactions

Metathetical reactions of thiyl radicals are of general occurrence in the photolysis and thermolysis of disulfides. To give one example, co-photolysis of  $\text{CH}_3\text{SSCH}_3$  and  $\text{C}_2\text{H}_5\text{SSC}_2\text{H}_5$ <sup>75</sup> led to the formation of large amounts of  $\text{CH}_3\text{SSC}_2\text{H}_5$ , far exceeding the amount expected on the basis of  $\text{CH}_3\text{S} + \text{C}_2\text{H}_5\text{S}$  combination:

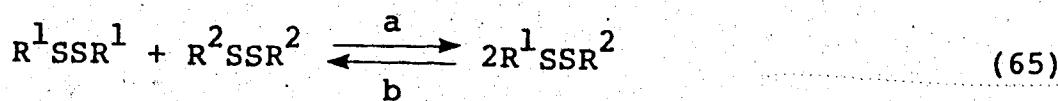

The chain thus initiated is sufficiently long that this system is frequently used for the synthesis of asymmetrical disulfides. Unfortunately, no rate constants have been reported for these reactions. Recently however it was shown that HS radicals undergo an analogous metathetical reaction with  $\text{CH}_3\text{SCH}_3$ :

and the rate parameters were estimated to be  $A \sim 10^9-10^{10}$   
 $\text{cm}^3 \text{ mol}^{-1} \text{ s}^{-1}$  and  $E_a < 2.7 \text{ kcal mol}^{-1}$ .<sup>40</sup>

Disproportionation of dialkyldisulfides is found to be an equilibrium reaction and a number of studies have been reported by Haraldson *et al.* and Olander and Sunner.<sup>24,76</sup> Haraldson and coworkers irradiated a number of pairs of symmetrical disulfides and from the asymmetrical disulfide yield

obtained the equilibrium constant,

$$K_{65} = k_{65a}/k_{65b} \quad (66)$$

at 25°C and 60°C. The statistically expected value for  $K_{65}$  is 4; experimentally, it was found to be ~5.5 for groups such as  $\text{CH}_3$ ,  $\text{C}_2\text{H}_5$ , and  $i\text{-C}_3\text{H}_7$  and was also temperature independent, i.e.,  $\Delta H_{65} = 0$ . However,  $K_{65} = 24$  for the mixture  $(\text{C}_2\text{H}_5\text{S})_2 - (t\text{-C}_4\text{H}_9\text{S})_2$ , thus favoring  $\text{C}_2\text{H}_5\text{SSt-C}_4\text{H}_9$ . This result was attributed to the presence of rigid conformations in the *t*-butyldisulfide molecule.

#### 4. Transition State Theory for Bimolecular Reactions.

Transition state theory formulates the rate of any reaction in terms of a "transition" state - a molecular

complex having the proper configuration in space and a minimum energy for the reaction to occur - situated on top of the potential energy barrier along the reaction path. The nature of this potential energy barrier can be calculated as a function of the relative positions of the different nuclei or as a function of different atom positions. Collision theory relates the minimum energy necessary for the reactants to reach the top of the energy barrier and attain the configuration of the transition state - or the activated complex - to the energy of activation.

Transition state theory further assumes an equilibrium between reactants, e.g., A and B and the activated complex  $AB^{\ddagger}$ . The equilibrium constant  $K^{\ddagger}$  is then

$$K^{\ddagger} = \frac{[AB^{\ddagger}]}{[A][B]} \quad (67)$$

The bimolecular rate constant  $k_{AB}$ , which is the rate of passage of the complex over the potential energy barrier, can then be expressed as

$$k_{AB} = \left(\frac{kT}{h}\right) K^{\ddagger} \quad (68)$$

where k is the Boltzmann constant, T the temperature and h, Planck's constant. Now since

$$-RT\ln K^{\ddagger} = \Delta H^{\ddagger} - T\Delta S^{\ddagger} \quad (69)$$

equation (69) can be expressed as

$$k_{AB} = \frac{kT}{h} e^{\Delta S_{AB}^{\ddagger}/R} e^{-\Delta H_{AB}^{\ddagger}/RT} \quad (70)$$

From the Arrhenius form of the rate constant,

$$k = A \cdot e^{-E/RT} \quad (71)$$

it is seen that

$$A = \left(\frac{ekT}{h}\right) e^{\Delta S_{AB}^{\ddagger}/R} \text{ and } E = \Delta H_{AB}^{\ddagger} + RT \quad (72)$$

For ground state molecules the standard entropies are either known or can be calculated from statistical mechanics with fairly good precision. Another, more rapid and nearly as accurate a method, developed by Benson,<sup>77</sup> is an empirical one based on additivities of molecular properties with the assumption that the activated complex is a rigid molecule. In this way, lower limits of  $\Delta S^{\ddagger}$  are estimated. The latter method is extremely useful in that it can be applied for the calculation of the entropies of activated complexes. In such calculations the translational, rotational, symmetry and spin contributions to the entropy can be readily evaluated; the vibrational contributions are less straightforward and the usual method is to adjust the normal frequencies on the basis of those of analogous compounds. For reactions involving a light atom, such

as H or D, with a large polyatomic molecule, the transition state complex has approximately the same intrinsic entropy as the substrate and hence,

$$\Delta S^{\ddagger} = (S^{\circ}(\text{Substrate}) + 1.4) - (S^{\circ}(\text{Substrate}) + S^{\circ}(H)) \quad (73)$$

where 1.4 is the spin correction. Symmetry corrections may also be necessary.

In this way, preexponential factors for reactions for which experimental data are not available can be calculated, usually with a fair degree of precision. Of perhaps more significance however is that valuable information can be brought to light on the activated complex.

### 5. Computer Modeling of Chemical Reactions.

With the general availability of high performance digital computers, computer modeling of complex chemical reactions has become a powerful method in gas phase reaction kinetics for the interpretation of experimental data in terms of a detailed mechanism and the corresponding rate constants.

Computer modeling of chemical reactions consists of the construction of a model mechanism and the subsequent numerical integration of its representative set of coupled simultaneous ordinary differential equations.<sup>78</sup> The single independent variable is time, the dependent

variables are the concentrations of all chemical species that change during the course of the reaction.

The model mechanism consists of a sequence of elementary reactions and a set of the corresponding rate constants.

It is varied (some elementary reactions are deleted or new ones are added, the values of unknown or uncertain rate constants are adjusted) until satisfactory agreement between the observed and calculated time dependence of the concentrations is achieved.

In chemical kinetics the rate equations can be directly deduced from the mechanism and they provide explicit algebraic expressions for the time derivatives of all species concentrations, as shown in the following simple example

$$\frac{d[A]}{dt} = -2k_{74}[A]^2 - k_{75}[A], \quad (76)$$

$$\frac{d[B]}{dt} = k_{75}[A], \quad (77)$$

$$\text{and } \frac{d[C]}{dt} = k_{74}[A]^2. \quad (78)$$

Complex reaction mechanisms usually consist of numerous elementary reactions having a wide range in rates, especially when transient intermediates at very

low concentrations are created and consumed rapidly.

This characteristic results in a so-called "stiff" set of differential equations, the solution of which requires extremely short integration steps and hence very long computation times using conventional methods.

For the numerical integration, usually an algorithm developed by C.W. Gear,<sup>79</sup> or one based on its subsequent development, is used. The program applies a multistep, predictor-corrector method, and successfully overcomes the difficulty presented by the "stiffness" of the differential equations. It also continuously adjusts the time increments in order to reduce the computational times.

Computer modeling of complex chemical reactions has been found to be a very useful method, both for testing of the compatibility of a suggested mechanism with the experimental data, and for the derivation of values for unknown rate constants of elementary reactions. In more recent years it has become a powerful method for the simulation of the ongoing chemistry of polluted atmospheres.<sup>80</sup>

#### 6. Aim of the Present Investigation.

As seen from the above discussion the results available to date strongly suggest that atom and radical attack on alkylsulfides and disulfides takes place

mainly, in some cases exclusively, at the nonbonding 3p orbital of sulfur. Kinetic data however are sparse and, for the particular case of H atoms, have only been determined for the  $H + COS$ ,  $C_2H_4S$ , and  $CH_3SCH_3$  systems.

The reactions of H atoms with disulfides have not been investigated at all.

It was therefore decided to initiate a kinetic-mechanistic study of the gas phase reactions of H atoms with low molecular weight disulfides with the aim of elucidating the nature of the primary processes and to establish the overall mechanism by means of product analysis, together with the effects of exposure time, concentration and temperature on the product quantum yields. Next, rate coefficients for the primary reaction would be established in competition with the  $H + C_2H_4$  reaction, for which the rate parameters are well known. From the measured activation energies and preexponential factors, it was anticipated that some correlation with the exothermicities of the reactions could be established, and, more importantly, that knowledge concerning the nature of the activated complex could be deduced. As a corollary to these studies, some aspects of the chemical reactivity of simple alkylthiyl radicals can be brought to light.

The following disulfides were selected for study.

- (a) dimethyldisulfide, the simplest in the series. It was anticipated that the overall mechanism would be relatively uncomplicated since few radicals can be produced, and hence kinetic-mechanistic interpretation of the results would be fairly straightforward;
- (b) diethyldisulfide, in order to see whether increasing alkyl substitution would have any effect on the nature of the primary process;
- (c) ethylmethyldisulfide, where the possibility of competing primary processes can be investigated;
- (d) bis(trifluoromethyl)disulfide , to study the possible effects of strongly electron-withdrawing substituents on the nature and rate of the primary reaction.

Finally, the H + diethylsulfide reaction was investigated in order to determine whether the metathetical alkyl displacement reaction previously established for the H + dimethylsulfide reaction is common to alkylsulfides.

## CHAPTER II

### EXPERIMENTAL

#### 1. High Vacuum System.

A conventional high vacuum system (Figure 1), consisting of pumps, two distillation units (one for purification of substrates, the other for separation of products), a photolytic assembly, gas storage bulbs, Töepler pump-gas buret and metering units, has been used throughout. The system was pumped down to  $10^{-6}$  Torr by means of a two stage mercury diffusion pump backed by a Welch Duoseal mechanical pump. Delmar float and Helium tested Hoke valves, and Delmar Teflon plug stopcocks were used throughout the system in order to minimize loss of the sulfur-containing products during gas transfers. Absolute pressures were measured with either a Mcleod gauge, a constant volume mercury manometer, a Barocel electronic manometer, Model 1174 Type 570A-10T, or an MKS Baratron pressure meter, serial 19854, Type 170M-6B, associated with a high temperature pressure head having a 100 torr pressure range, serial 19853, Type 315BHS-100. Pirani tubes (Consolidated Vacuum Corporation Catalogue No. GP-001), conveniently located in the system, were used to monitor gas transfers. The Mcleod gauge was used to calibrate the Pirani Vacuum gauges (Type G-140C). The distillation trains consisted of several U- and multi-coil traps, and a solid nitrogen

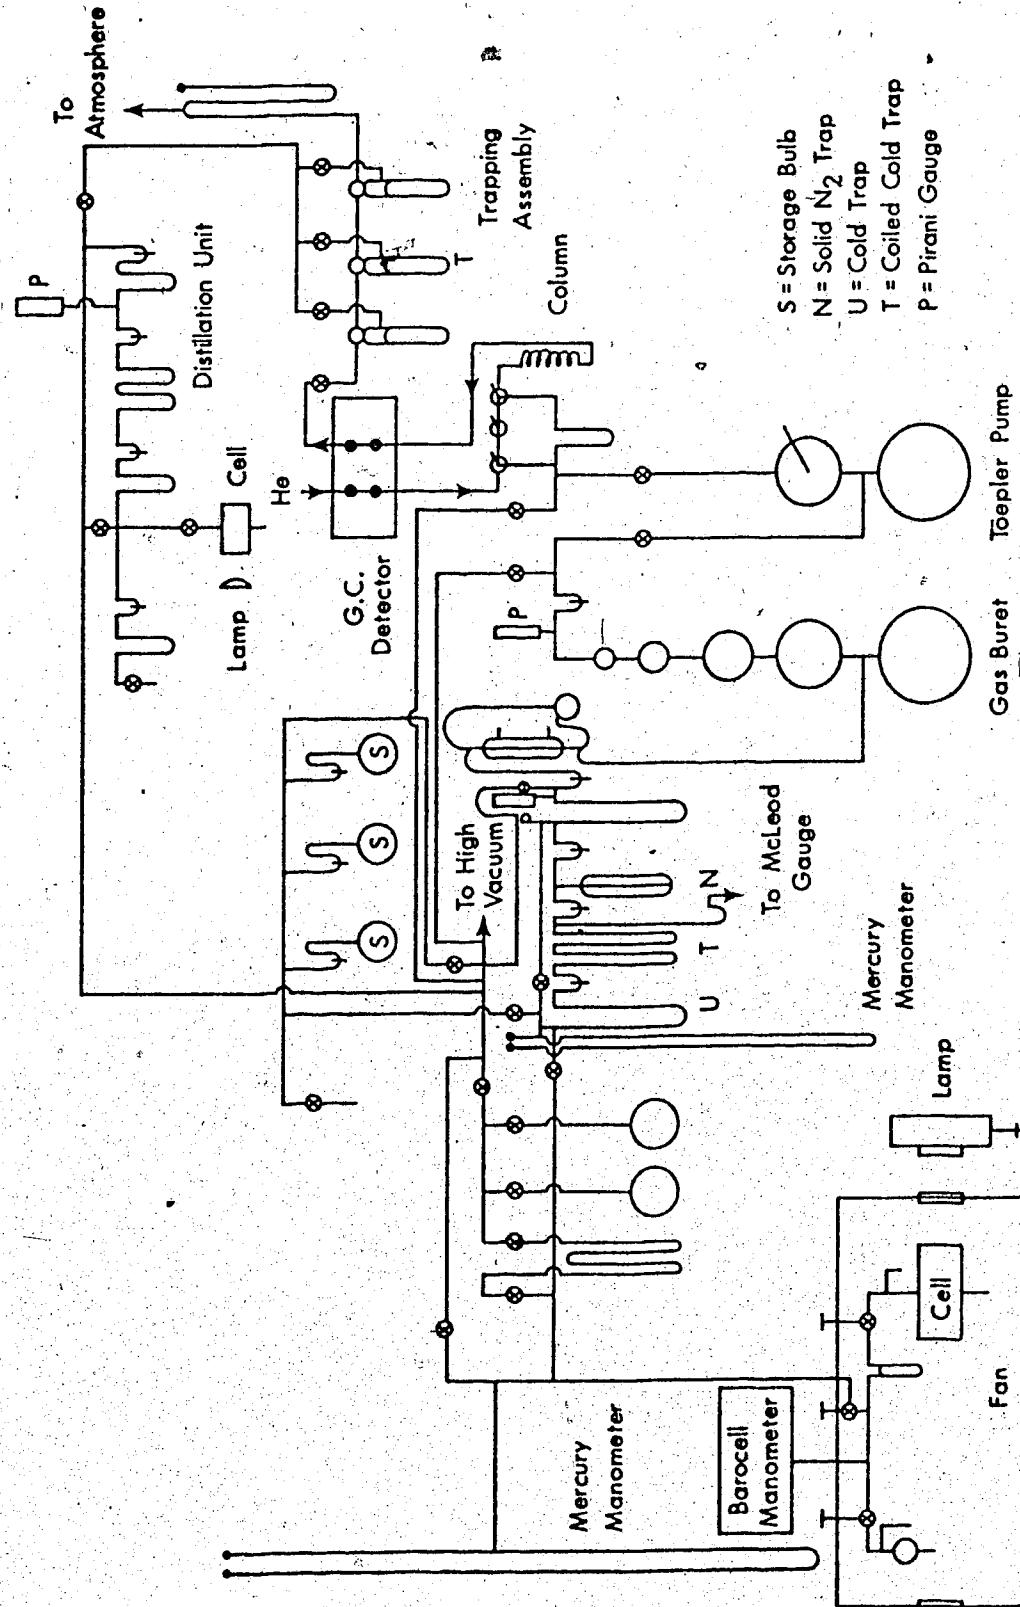

FIGURE 1. The high vacuum system.

trap interconnected by mercury float and Hoke valves.

Samples were introduced to the attached gas chromatograph from the Toepler pump and gas buret into the trapping assembly. The latter was used in conjunction with the gas chromatograph for preparative purification or product separation.

## 2. Photolytic Assembly.

The photolytic assembly, illustrated in Figure 2, was specially designed for the study of H atom reactions with low vapor pressure disulfides. The cylindrical quartz reaction cell (5 x 10 cm), of volume 200 cm<sup>3</sup>, including the cold finger and the dead space between the cell and the shutoff valve, was enclosed in an aluminum block furnace insulated by a 2 cm thickness of glass wool and equipped with iron-constantan thermocouples connected to a readout dial. The furnace faces had aluminum brackets in which quartz filters could be inserted. The furnace was heated electrically to temperatures in the range 25-199°C, by two 10 cm pencil heaters placed in axial holes, each located at the furnace face, in the two halves of the aluminum block furnace. Temperatures ( $\pm 1^\circ\text{C}$ ) were monitored by standard iron-constantan thermocouples and a thermometer placed in an axial hole located at the face of the block furnace.

The whole assembly, consisting of a U-trap, a storage bulb, Hoke valves, a calibrated volume, and the

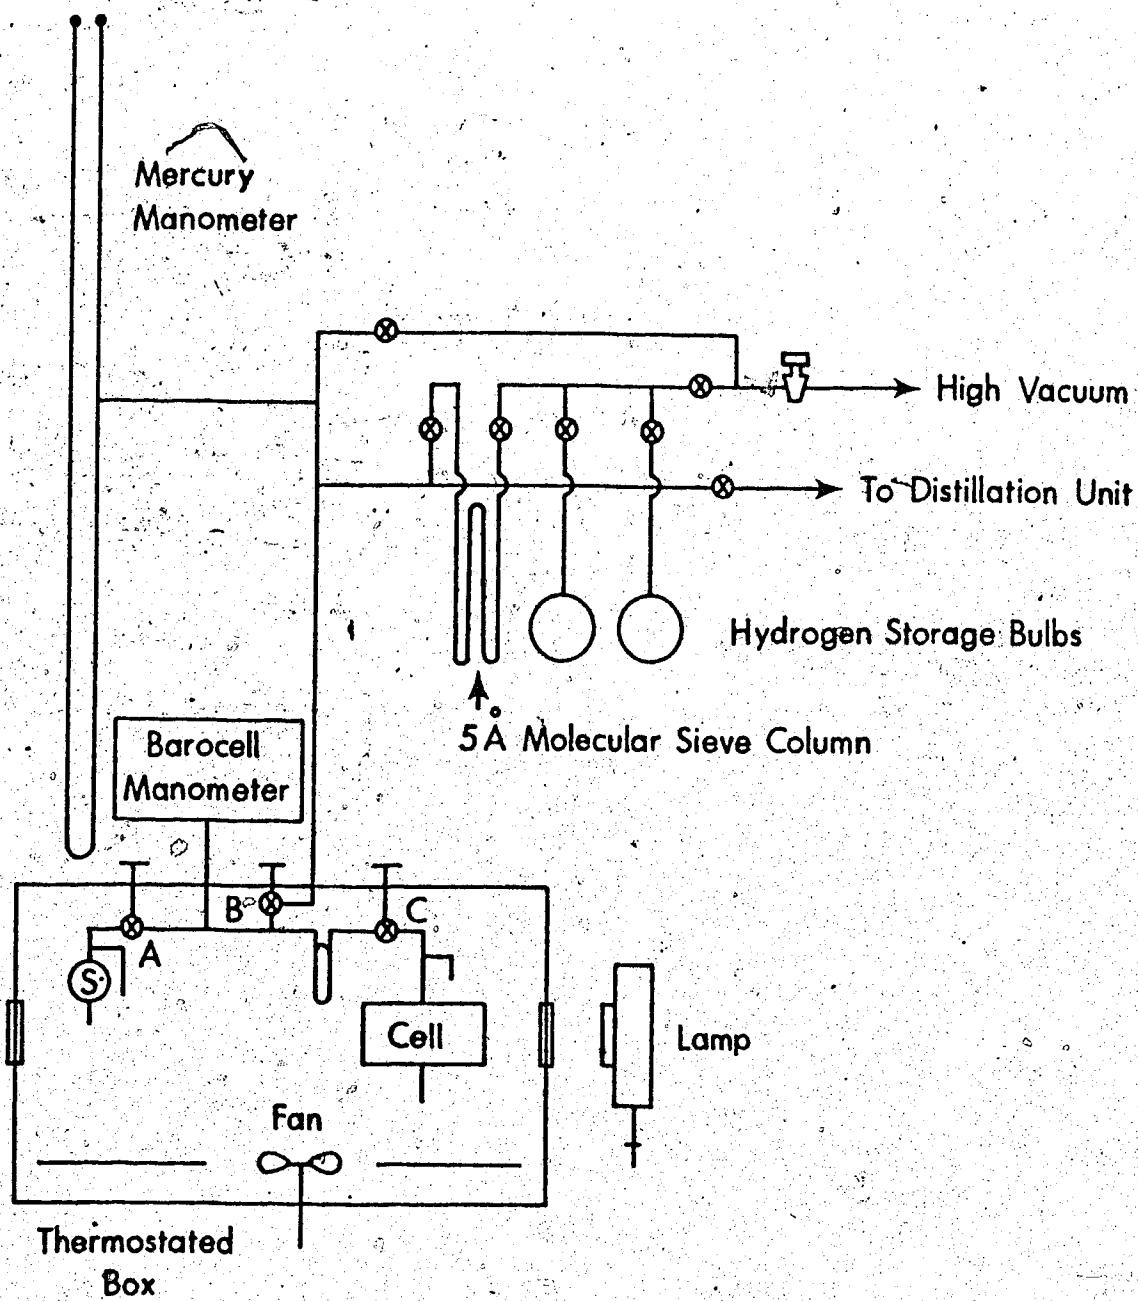

FIGURE 2. The photolytic assembly.

cell enclosed in an aluminum block furnace, was in a thermostated box (100 x 70 x 50 cm), constructed of asbestos, 15 mm thick. The box was heated electrically to constant temperatures in the range 25-65°C, by a spiral heater located at the bottom of the box. The thermostated housing served to maintain the substrate in the gaseous state during transfer to the reaction cell, and was also found to lead to more quantitative product transfer from the reaction cell to the analytical system. To ensure uniform temperature ( $\pm 1^\circ\text{C}$ ) inside the box the air was circulated by a fan, driven by an induction motor.

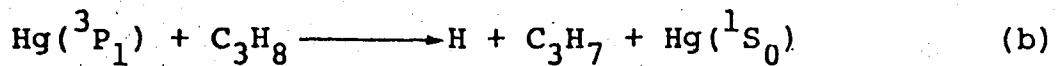

### 3. Light Sources and Actinometry.

For the H atom reactions, the light source was a Hanovia low pressure Hg resonance lamp equipped with a 253.7 nm Baird Atomic interference filter.

For photolytic synthetic purposes, a Hanovia medium pressure Hg lamp, Model 30620, was used without a filter. This lamp and the photolytic assembly for the preparative purposes are located at the top section of Figure 1.

The light intensity of the low pressure Hg resonance lamp was determined by propane actinometry.<sup>81</sup> Under conditions of low lamp intensities the only elementary processes of importance are the following:

Back<sup>82</sup> has shown that  $\phi(\text{H}_2)$ , the quantum yield of hydrogen production, decreases with irradiation time until the concentration of  $\text{C}_3\text{H}_6$  reaches a steady state, after which  $\phi(\text{H}_2) = 0.581$  at  $27^\circ\text{C}$  and remains constant. In the present experiments, about 600 torr propane was irradiated repeatedly until the rate of hydrogen production became constant and this value was used to calculate the lamp intensity. The lamp intensity was kept as low as possible, of the order of  $0.014 \mu\text{einstein min}^{-1}$ , in order to minimize radical-radical reactions and to ensure a low concentration of H atoms.

#### 4. Materials.

All materials used in this study were of research grade and were routinely purified by distillation *in vacuo*. Table V lists the sources and methods of purification of the various compounds used. The purities of all the distillates collected were further checked by gc.

TABLE V  
Sources of Materials Used and Purification Procedures

Material	Source	Grade and Purity	Purification
Hydrogen	Airco	Research grade >99.9%	distilled through at 5 Å molecular sieve column
Ethylene	Phillips	Research grade >99.5%	distilled at -160°C

Diethylsulfide	Baker	Research grade	gc 10 ft tricresyl- phosphate at 25°C
Bis(trifluoromethyl)- disulfide	Peninsular Chemical Research	Technical (~80%)	distilled at -130°C
Thiirane	Peninsular Chemical Research	Technical (~80%)	distilled at -130°C

Ethylmethyldisulfide was prepared from the photolysis of equimolar amounts of dimethyldisulfide and diethyl-disulfide. It was purified by gc using a 4 ft 10% tricresylphosphate on Chromosorb W column operated at room temperature using helium as carrier gas/at a flow rate of  $110 \text{ cm}^3 \text{ min}^{-1}$  (retention time, 41 min). The purified disulfide was always stored *in vacuo* at  $-196^\circ\text{C}$ .

### 5. The Analytical System.

The analytical system used, illustrated in Figure 1, consisted of a calibrated gas burette connected directly to the injection loop of a gas chromatograph. The detector was a Gow-Mac Model TRIIB, which was powered by a Gow-Mac power supply Model 9999-C operated at  $110^\circ\text{C}$ . The unit was operated at 200 mA, and the results were read out on a Sargent recorder, Model S-72180, operated at a chart speed of one inch per minute. Helium, dried and purified by passage through a  $5 \text{ \AA}$  molecular sieve column, was used as carrier gas, at flow rates determined by an open-end oil manometer which was calibrated against a soap bubble flowmeter. The types of gc columns used, the operating conditions and retention times of the various compounds encountered in this study are summarized in Table VI.

The gc effluent could be passed through a series of coiled cold traps in which desired compounds could be

isolated for further analysis and identification.

Provisions were also made to bypass the detector for the cases of unstable compounds.

Product identification was made initially on the basis of comparison of the gc retention times with those of authentic samples and then subsequently confirmed by mass spectrometric analysis. The detector response was calibrated from authentic samples and checked periodically for reproducibility. Peak areas were measured with an Otto planimeter.

#### 6. Operational Procedure.

The reaction cell and the thermostated box were heated overnight to the desired reaction temperature and 65°C, respectively. The lamp was allowed to equilibrate at least 30 minutes prior to irradiation. Control experiments were made at each temperature in order to check whether thermal decomposition of the substrate was involved. All experiments were carried out in the gas phase.

The substrate was expanded from the storage bulb to the reaction cell and then the Hoke valves A and B, shown in Figure II, were shut off. Its pressure was measured by the Barocel electronic manometer and then the Hoke valve C was shut off. The substrate (< 30 torr) was condensed in the cold finger of the photolytic cell

by using liquid nitrogen contained in a small Dewar flask introduced into the thermostated box through a window.

Excess substrate was pumped out by opening the Hoke valve B to the high vacuum.

Approximately  $580 \pm 10$  torr hydrogen was then admitted into the reaction cell. The hydrogen pressure was measured with a mercury manometer and then the Hoke valve C was shut off. Excess hydrogen was transferred to the storage section by condensing it in a  $5\text{ \AA}$  molecular sieve column kept at  $-196^{\circ}\text{C}$ , then expanding it into two hydrogen storage bulbs.

The reaction mixtures were equilibrated for 30 minutes before irradiation. After photolysis, the hydrogen was pumped out very slowly through a series of cold traps, five at  $-196^{\circ}\text{C}$  and one at  $-210^{\circ}\text{C}$ , keeping the pressure reading on the Barocel electronic manometer in the range 1-2 torr. The remaining fraction, consisting of substrate and products, was analyzed by gc on the 10 ft tricresylphosphate column.

For experiments carried out in the presence of ethylene the substrate was condensed in the reaction cell and the Hoke valves A and C were shut off. Ethylene was admitted into a calibrated volume, and then Hoke valve B was shut off. The ethylene pressure ( $< 30$  torr) was measured by the Barocel electronic manometer. The Hoke valve C was then opened and the measured amount of

ethylene was condensed into the cold finger of the photolytic cell. The remaining procedures were similar to those described above, except that after pumping out the hydrogen, ethylene was distilled from the reaction mixture at -160°C prior to analysis of the remaining fraction.

In the experiments with diethylsulfide, the fraction volatile at -160°C, consisting of C<sub>2</sub>H<sub>4</sub> and C<sub>2</sub>H<sub>6</sub>, was analyzed on an 8 ft porapak N column, while the fraction volatile at -130°C was analyzed on a 10 ft tricresyl-phosphate column. In order to ascertain whether methane was formed in the reaction the hydrogen fraction was condensed on a 3 Å molecular sieve column. The column was then heated to 100°C and the fraction volatile at this temperature was analyzed on a 10 ft 3 Å molecular sieve column.

It was found that 24 hours were required for quantitative transfer of the products from the reaction cell to the gc injection port.

## CHAPTER III

### THE REACTIONS OF HYDROGEN ATOMS WITH DIMETHYLDISULFIDE

#### Results

The mercury photosensitization of  $H_2$  in the presence of  $CH_3SSCH_3$  led to the formation of only one retrievable product,  $CH_3SH$ . Polymer formation on the cell window was quite extensive, hence actinometric measurements were performed before and after each experiment and the average value was taken as the absorbed light intensity. The extent of quenching of the excited mercury atoms by  $CH_3SSCH_3$  or  $C_2H_4$  at the highest concentrations used was estimated to be less than 5%; see appendix A for the calculation. Control experiments made at each temperature indicated that  $CH_3SSCH_3$  was thermally stable in the temperature range 25-155°C.

#### 1. Effects of time, $CH_3SSCH_3$ concentration and temperature on $\phi(CH_3SH)$ .

In the first set of experiments, the quantum yield of  $CH_3SH$  was determined at 60°C as a function of exposure time at a constant  $CH_3SSCH_3$  pressure of 10.06 Torr. The results, listed in Table VII, show that the quantum yield of  $CH_3SH$  was approximately 2.1 and invariant with exposure time up to 60 minutes, hence  $CH_3SH$  must be formed in a primary process.

<sup>c</sup> standard error

Next,  $\phi(\text{CH}_3\text{SH})$  was determined as a function of  $\text{CH}_3\text{SSCH}_3$  pressure. The results (Table VIII) show that  $\phi(\text{CH}_3\text{SH})$  is also independent of  $\text{CH}_3\text{SSCH}_3$  pressure in the range 2-20 Torr, indicating that scavenging of H atoms by  $\text{CH}_3\text{SSCH}_3$  is complete.

The results in Tables VII and VIII show that  $\phi(\text{CH}_3\text{SH})$  was also invariant with lamp intensity in the range 0.011 - 0.016  $\mu\text{einsteins min}^{-1}$ . This result constitutes additional evidence to the effect that most, if not all, of the  $\text{CH}_3\text{SH}$  is formed in a primary process.

The effect of temperature on  $\phi(\text{CH}_3\text{SH})$  for a mixture of 580 Torr hydrogen and 5 Torr  $\text{CH}_3\text{SSCH}_3$  was examined over the range 25-120°C. The results, listed in Table IX, show that increasing the temperature has no effect on the quantum yield of  $\text{CH}_3\text{SH}$ , and it can therefore be concluded that side reactions such as thermolysis and/or secondary decomposition of  $\text{CH}_3\text{SH}$  do not take place within the temperature range examined.

## 2. Experiments in the presence of ethylene.

In the presence of  $\text{C}_2\text{H}_4$  several additional reaction products were formed, three of which were identified as  $n\text{-C}_4\text{H}_{10}$ ,  $\text{C}_2\text{H}_6$ , and  $\text{CH}_3\text{SC}_2\text{H}_5$ ; polymer formation was greatly reduced. Ethane, which was identified as a product, could not be separated from the large amounts of ethylene and was, therefore, not determined.

<sup>b</sup> number of experiments

quantitatively. Product quantum yields for a mixture of 580 Torr H<sub>2</sub> and 5 Torr CH<sub>3</sub>SSCH<sub>3</sub> in the presence of increasing amounts of ethylene at five different temperatures are given in Table X where it is seen that  $\phi(\text{CH}_3\text{SH})$  decreases with increasing pressure of ethylene, owing to the competitive scavenging of H atoms by C<sub>2</sub>H<sub>4</sub>,

### Discussion

At the relative H<sub>2</sub>/CH<sub>3</sub>SSCH<sub>3</sub> and H<sub>2</sub>/CH<sub>3</sub>SSCH<sub>3</sub>/C<sub>2</sub>H<sub>4</sub> concentrations used in this work it is estimated that >95% of the excited mercury atoms are quenched by H<sub>2</sub>:

Although  $\phi(\text{HgH}) = 0.67^{83-85}$  the lifetime of HgH is so short that the overall kinetics are indistinguishable from those of H atoms, for which  $\phi(\text{H}) = 2.0.^{86}$

Since methanethiol is the only product of the reaction, and its invariance with exposure time indicates that it is a primary product, the following simple mechanism would seem to apply:

TABLE X

Effect of  $C_2H_4$  Pressure and Temperature on  $\phi(CH_3SH)$ <sup>a</sup>

12.5	2.50	1.09	0.917
15.0	3.00	0.980	1.02

<sup>a</sup>Photolysis time = 45 min;  $I_a = 1.27 \times 10^{-8}$  einstein  $min^{-1}$

$P(H_2) = 580 \pm 10$  Torr;  $P(CH_3SSCH_3) = 5.00$  Torr.

From this mechanism  $\phi(\text{CH}_3\text{SH}) = \phi(1) + \phi(2b) = 2.1$  and  $\phi(1)/2 = \phi(2a) + \phi(2b)$ . The value of  $\phi(2b)/\phi(2a)$  reported by Rao and Knight<sup>57a</sup> is ~0.05 (Lossing and coworkers' value of 0.4<sup>87</sup> is probably erroneous), from which  $\phi(1)/2 = \phi(2b)/0.05 + \phi(2b) = 21\phi(2b)$ . Therefore,

$$\phi(1) = 42\phi(2b), \phi(2b) = 2.1/43 \sim 0.05$$

and  $\phi(1) = 2.05$  or, within experimental error, 2.0. This means that scavenging of H atoms by dimethyldisulfide is complete and the only reaction consuming H atoms is reaction (1). Since  $\phi(\text{CH}_3\text{SH})$  is approximately equal to 2.1 between 25 and 120°, it is concluded that  $k_{2b}/k_{2a}$  is temperature independent in this temperature range, i.e.,  $E_{2b}$  is zero or negligibly small.

The absence of the radical combination products such as  $\text{CH}_3\text{SCH}_2\text{SSCH}_3$  and  $(\text{CH}_2\text{SSCH}_3)_2$  which are expected to be stable under the conditions employed, is evidence that the abstractive route to  $\text{H}_2$  formation does not occur:

It was not possible to ascertain whether  $\text{H}_2$  is one of the

reaction products, however, on the basis of the exothermicities of reaction (1) ( $\approx -21.4$  kcal mol $^{-1}$ ) and reaction (3) ( $\approx -8$  kcal mol $^{-1}$ ) it is very likely that the latter will be relatively slow compared to the former. Reaction (3) may, however become important at higher temperatures.

On the same basis, the occurrence of H abstraction by  $\text{CH}_3\text{S}$ ,

for which  $\Delta H \sim 7$  kcal mol $^{-1}$ , does not appear to be important. Moreover, this reaction is expected to feature a substantial activation energy whereas  $\phi(\text{CH}_3\text{SH})$  was observed to be independent of temperature up to 120°C.

The following metathetical primary processes can also be discounted since  $\text{CH}_4$ ,  $\text{CH}_3\text{SCH}_3$  and  $\text{H}_2\text{S}$  were demonstrably absent:

The detection of  $\text{CH}_3\text{SSH}$  as a product, if formed, is not possible because  $\text{CH}_3\text{SSH}$  is known<sup>40,88</sup> to be very unstable and decomposes to  $\text{CH}_3\text{SH}$  and sulfur. Finally, the overall stoichiometric balance indicates that the following reactions,

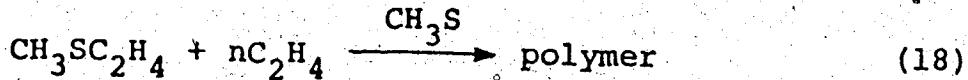

are of very minor importance.

In the presence of ethylene a complete hypothetical reaction sequence would consist of steps (1), (2) and (9)-(18)

The metathetical radical displacement reaction,

probably requires a considerable activation energy hence it was assumed to be unimportant in this system. Also, reactions (10), (11), (12), (13), (14) and (15) can be discounted since  $\text{CH}_3\text{SCH}_2\text{H}_3$ ,  $\text{CH}_3\text{SC}_2\text{H}_4\text{SCH}_3$ ,  $\text{CH}_3\text{SC}_4\text{H}_9$ , and  $(\text{CH}_3\text{SC}_2\text{H}_4)_2$  were demonstrably absent. Finally, step (18) does not seem to be important since polymer formation was greatly suppressed in the presence of  $\text{C}_2\text{H}_4$ . Steady state treatment of steps (1), (2), (9), (16) and (17) leads to the following rate expression:

$$\phi(\text{CH}_3\text{SH})^{-1} = \frac{1}{2(1+\alpha)} + \frac{1}{2(1+\alpha)} \frac{k_9[\text{C}_2\text{H}_4]}{k_1[\text{CH}_3\text{SSCH}_3]} \quad I$$

where  $\alpha \approx \Sigma k_{\text{disproportionation}} / \Sigma k_{\text{combination}}$  of the  $\text{CH}_3\text{S}$  radical resulting in the formation of  $\text{CH}_3\text{SH}$  and in the disappearance of  $\text{CH}_3\text{S}$  by other reactions, respectively.

Plots of equation I, illustrated in Figure 3, are indeed linear at the five temperatures studied and feature a common intercept. The least mean square slopes and intercepts are summarized in Table XI. The average value

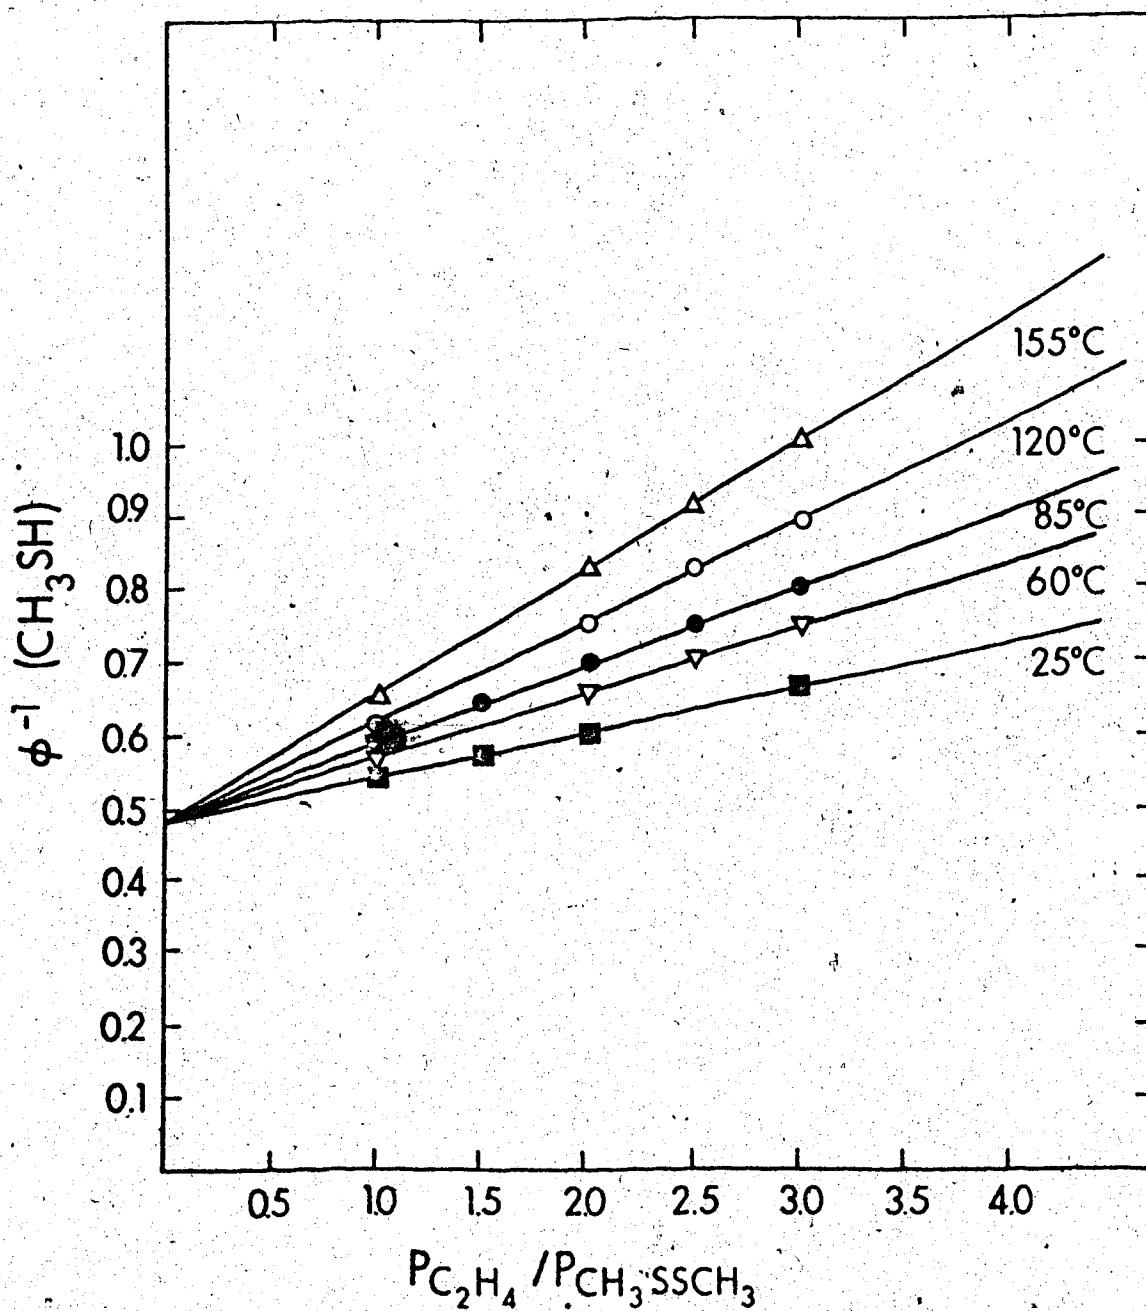

FIGURE 3.  $\phi(\text{CH}_3\text{SH})^{-1}$  versus  $P[\text{C}_2\text{H}_4]/P[\text{CH}_3\text{SSCH}_3]$  at 25, 60, 85, 120 and 155°C.  $P(\text{H}_2) = 580 \pm 10$  Torr;  $P(\text{C}_2\text{H}_4) + P(\text{CH}_3\text{SSCH}_3) = 10-20$  Torr; photolysis time, 45 minutes.

TABLE XI  
Slopes and Intercepts of the Plots in Figure 3<sup>a</sup>

T, °C	Slope	Intercept	$k_9/k_1$
25	$0.0645 \pm 0.0015$	$0.475 \pm 0.003$	$0.136 \pm 0.003$
60	$0.0897 \pm 0.0020$	$0.478 \pm 0.005$	$0.189 \pm 0.004$
85	$0.111 \pm 0.002$	$0.474 \pm 0.004$	$0.234 \pm 0.004$
120	$0.140 \pm 0.002$	$0.473 \pm 0.004$	$0.295 \pm 0.004$
155	$0.182 \pm 0.005$	$0.468 \pm 0.012$	$0.384 \pm 0.001$

<sup>a</sup>The errors are standard deviations

of  $\alpha$  is 0.059, in good agreement with the value of 0.05 reported in the literature.<sup>57a</sup> The values of  $k_9/k_1$ , also listed in Table XI, are plotted in the Arrhenius form in Figure 4, from which

$$\log(k_9/k_1) = (0.592 \pm 0.039) - (2000 \pm 64)/2.3RT$$

Taking the limiting high pressure rate parameters for step (9) as<sup>89</sup>

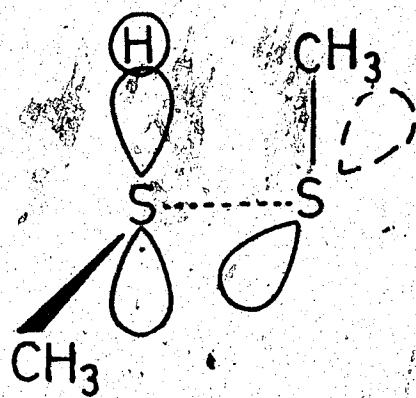

$$k_9 = (2.2 \pm 0.4) \times 10^{13} \exp[-(2066 \pm 83)/RT] \text{ cm}^3 \text{mol}^{-1} \text{s}^{-1},$$

those for step (1) are

$$k_1 = (5.7 \pm 1.2) \times 10^{12} \exp[-(100 \pm 100)/RT] \text{ cm}^3 \text{mol}^{-1} \text{s}^{-1}.$$

The experimental entropy of activation,  $\Delta S_{\text{exp}}^{\ddagger}$  = -26.2 e.u. for the standard state of 1 atm., suggests a very rigid transition state for the  $\text{H} + \text{CH}_3\text{SSCH}_3$  reaction.

If one assumes an activated complex of the type

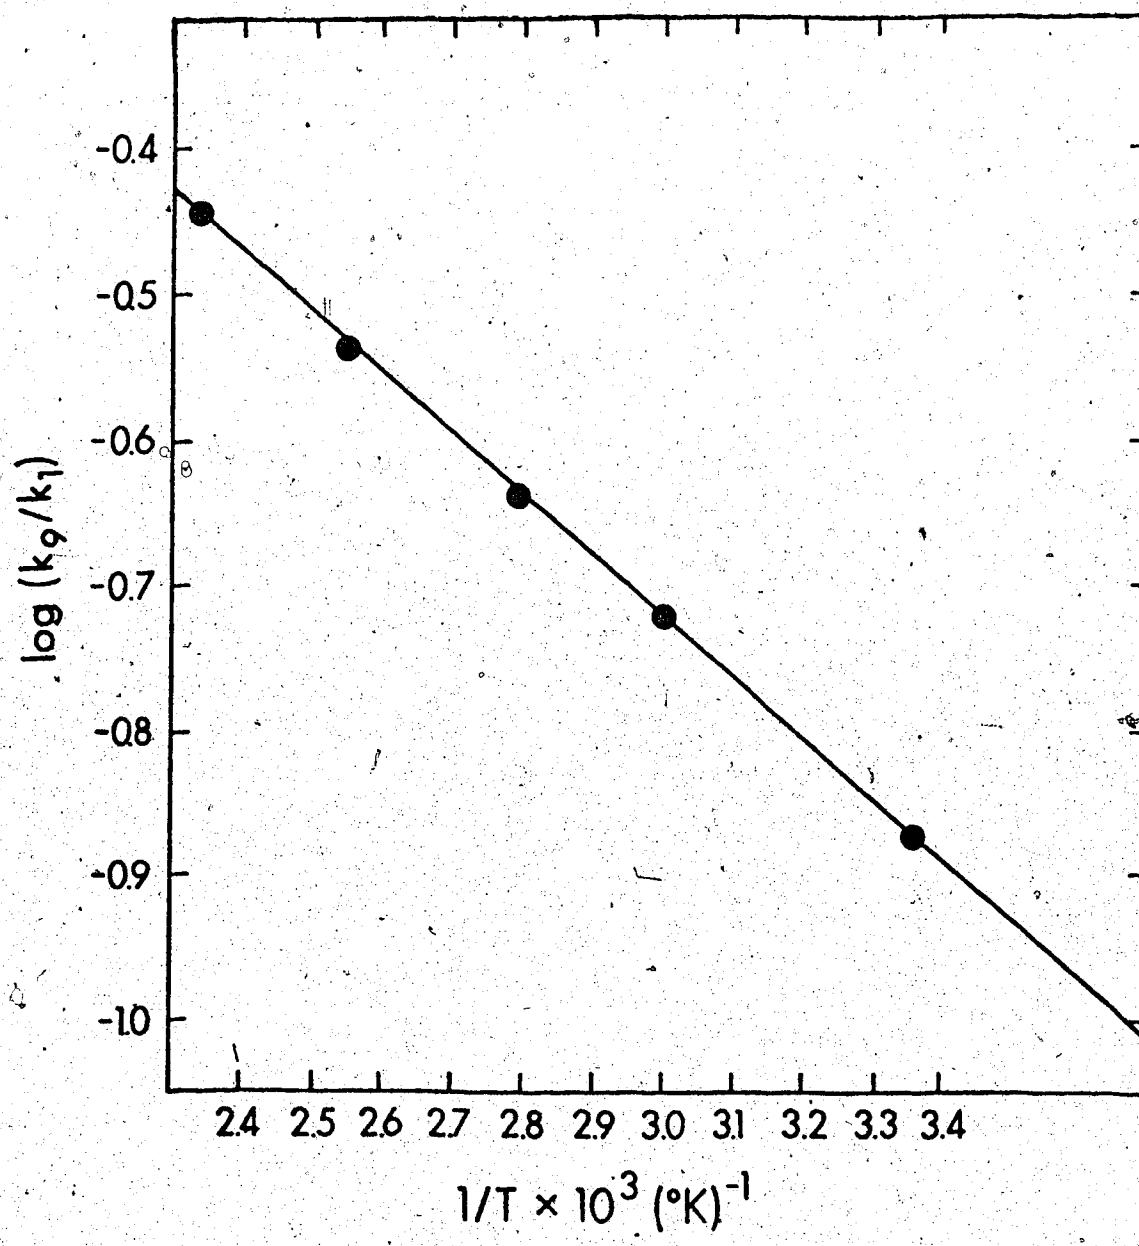

FIGURE 4. Arrhenius plot of  $k_9/k_1$  versus  $1/T$ .

$\Delta S^\ddagger$  can be calculated by Benson's method<sup>77</sup> since the gas phase structural parameters of  $\text{CH}_3\text{SSCH}_3$  have been reported.<sup>12,16</sup> The standard entropy of the activated complex,  $(\text{H}\cdot\text{CH}_3\text{SSCH}_3)^\ddagger$ , will then only require a correction of Rln 2 = 1.4 e.u. from the spin contribution since the contribution from the other factors, such as moments of inertia change, vibrational entropy consisting of contribution from each of the internal vibrations are small.

Thus,

$$S^\circ \ddagger = S^\circ (\text{CH}_3\text{SSCH}_3) + 1.4 \text{ e.u.}$$

$$\begin{aligned} \Delta S^\ddagger &= S^\circ (\text{CH}_3\text{SSCH}_3) + 1.4 \text{ e.u.} - S^\circ (\text{CH}_3\text{SSCH}_3) - S^\circ (\text{H}) \\ &= -26.0 \text{ e.u.} \end{aligned}$$

The good agreement with  $\Delta S_{\text{exp}}^\ddagger = -26.2 \text{ e.u.}$  suggests that the geometry of the assumed transition state is a good approximation to the actual case.

From the present results, it is not possible to draw any conclusion with regard to the intermediacy of the transient complex  $(\text{H}\cdot\text{CH}_3\text{SSCH}_3)$ ; however, to date, there is no indication that such complexes could have a finite lifetime in the gas phase.

## CHAPTER IV

### THE REACTIONS OF HYDROGEN ATOMS WITH DIETHYLDISULFIDE

#### Results

The mercury photosensitized decomposition of  $H_2$  in the presence of  $C_2H_5SSC_2H_5$  yields  $C_2H_5SH$  as the sole retrievable reaction product. Substantial amounts of polymer were formed at long exposure times. The extent of quenching of the excited mercury atoms by  $C_2H_5SSC_2H_5$  was estimated to be less than 5%. Control experiments made at each temperature showed that  $C_2H_5SSC_2H_5$  was thermally stable in the range 25-145°C.

#### 1. Effects of time, $C_2H_5SSC_2H_5$ concentration and temperature on $\phi(C_2H_5SH)$ .

The quantum yield of ethanethiol formed from the mercury sensitization of 580 Torr  $H_2$  in the presence of 5.0 Torr  $C_2H_5SSC_2H_5$  was determined at 60°C as a function of exposure time. The results are listed in Table XII. The quantum yield of ethanethiol at 60°C was 2.47 and independent of exposure time up to 70 minutes at constant  $C_2H_5SSC_2H_5$  pressure, hence  $C_2H_5SH$  must be formed in the primary process.

In the next series of experiments  $\phi(C_2H_5SH)$  was determined as a function of diethyldisulfide pressure.

TABLE XII  
Effect of Exposure Time on  $\phi(C_2H_5SH)$ <sup>a</sup>

<sup>a</sup>T = 60–62°C; P(H<sub>2</sub>) = 580 ± 10 Torr; P(C<sub>2</sub>H<sub>5</sub>SSC<sub>2</sub>H<sub>5</sub>) = 5.00 ± 0.02 Torr;

<sup>b</sup>I<sub>ave.</sub> (μeinstein min<sup>-1</sup>) × 10<sup>2</sup> = 1.24

<sup>c</sup>Number of experiments

The results, listed in Table XIII, show that  $\phi(C_2H_5SH)$  is also independent of  $C_2H_5SSC_2H_5$  pressure in the range 2-15 Torr, suggesting that scavenging of H atoms by  $C_2H_5SSC_2H_5$  is complete.

5.00 Torr diethyldisulfide were allowed to react with H atoms for 45 minutes at temperatures ranging from 25°C to 145°C. The results, shown in Table XIV, show that  $\phi(C_2H_5SH)$  is somewhat dependent on temperature, ranging from 2.32 at 25° to 2.84 at 145°C.

## 2. Effects of added ethylene.

In the presence of ethylene several additional reaction products were formed, three of which were identified as  $C_2H_6$ ,  $n-C_4H_{10}$  and  $C_2H_5SC_2H_5$ . One possible reaction product, ethylvinylsulfide, was demonstrably absent. Polymer formation was greatly suppressed. Product quantum yields from the mercury photosensitization of a mixture of 580 Torr  $H_2$  and 5.0 Torr  $C_2H_5SSC_2H_5$  in the presence of increasing amounts of ethylene at five different temperatures are given in Table XV where it is seen that  $\phi(C_2H_5SH)$  decreases with increasing pressure of  $C_2H_4$ , owing to the competitive scavenging of H atoms by  $C_2H_4$ .

### Discussion

Under the experimental conditions employed it is estimated that >95% of the  $\text{Hg}({}^3\text{P}_1)$  atoms are quenched by  $\text{H}_2$  and the overall process<sup>86</sup> is

for which  $\phi(\text{H}) = 2.0$ .

The absence of products such as  $\text{C}_2\text{H}_4$ ,  $\text{C}_2\text{H}_6$ ,  $\text{C}_4\text{H}_{10}$ ,  $\text{C}_2\text{H}_5\text{SC}_2\text{H}_5$  and  $\text{H}_2\text{S}$  can be taken as evidence that the following hypothetical primary processes do not occur:

The possibility of hydrogen abstraction taking place in parallel and in competition with  $\text{C}_2\text{H}_5\text{S}$  displacement,

cannot be discounted at this time, but kinetic considerations (*vide infra*) suggest that this reaction is unimportant within the temperature range examined.

Hence, and also by analogy with  $\text{H} + \text{CH}_3\text{SSCH}_3$  reaction, the sole primary process of significance is postulated to be:

The following secondary reactions may then take place:

However, at the low light intensities used in the present investigation, step (4) is unlikely to be important.

$\phi(\text{C}_2\text{H}_5\text{SH})$  varies between 2.32 at 25° and 2.84 at 145°C.

This may be due to the temperature dependence of step (2a),

or that of the abstractive route to thiol formation,

reaction (3). Now it has been shown (Chapter III) that

$k_d/k_c$  for  $\text{CH}_3\text{S}$  radicals is temperature independent: it

is therefore reasonable to assume that the same is true

for  $\text{C}_2\text{H}_5\text{S}$  and that the temperature dependence of  $\phi(\text{C}_2\text{H}_5\text{SH})$

is due to that of step (3). Note that the expected radical

combination products arising from the  $\text{CH}_3\text{CHSSC}_2\text{H}_5$  radical

formed in step (3) were not detected. Either this radical

is not stable and polymerizes, or the products were lost

during transfer. In any case, it will be shown that

inclusion of step (3) in the overall mechanism leads to

reasonable kinetic-mechanistic conclusions.

Thus, assuming that  $C_2H_5SH$  is formed exclusively via steps (1), (2a) and (3), then at  $25^\circ C$  where  $\phi(C_2H_5SH) = 2.32$ , the following steady state equations apply:

$$\phi(C_2H_5S) = 2\phi(2a) + 2\phi(2b) + \phi(3) = 2 \quad I$$

$$\phi(1) + \phi(2a) + \phi(3) = 2.32 \quad II$$

Given that scavenging of H atoms by  $C_2H_5SSC_2H_5$  is complete,  $\phi(1) = 2$  and  $\phi(2a) + \phi(3) = 0.32$ . From Knight and Smith's value of  $k_{2a}/k_{2b} = 0.13^{,68}$  equation I becomes

$$\phi(C_2H_5S) = 0.13\phi(2b) + 2\phi(2b) + 0.32 = 2 \quad III$$

$\phi(2a)$ ,  $\phi(2b)$  and  $\phi(3)$  were calculated from equation III and are listed in Table XVI at the five temperatures examined.

Further steady state treatment of steps (2a), (2b) and (3) leads to the following rate equation:

$$\frac{k_3}{(k_{2a} + k_{2b})^{1/2}} = \frac{\phi(3)}{\left(\frac{2-\phi(3)}{2}\right)^{1/2} [C_2H_5SSC_2H_5]} \quad IV$$

The Arrhenius plot of  $\phi(3)/((2-\phi(3))/2)^{1/2} [C_2H_5SSC_2H_5]$  (these values are also listed in Table XVI), Figure 5, is linear over the temperature range examined, in agreement with the above mechanism, and the slope yields

$(E_{2a} + E_{2b})/2 - E_3 = -3.61 \pm 0.09 \text{ kcal mol}^{-1}$ . If  $E_{2a} \sim 0$ , as was shown to be the case for  $CH_3S$  radicals, and since  $E_{2b}$  is zero or negligibly small, then this value corresponds

TABLE XVI

<sup>a</sup>  $[C_2H_5SSC_2H_5] = 5.0 / (62.361T)$

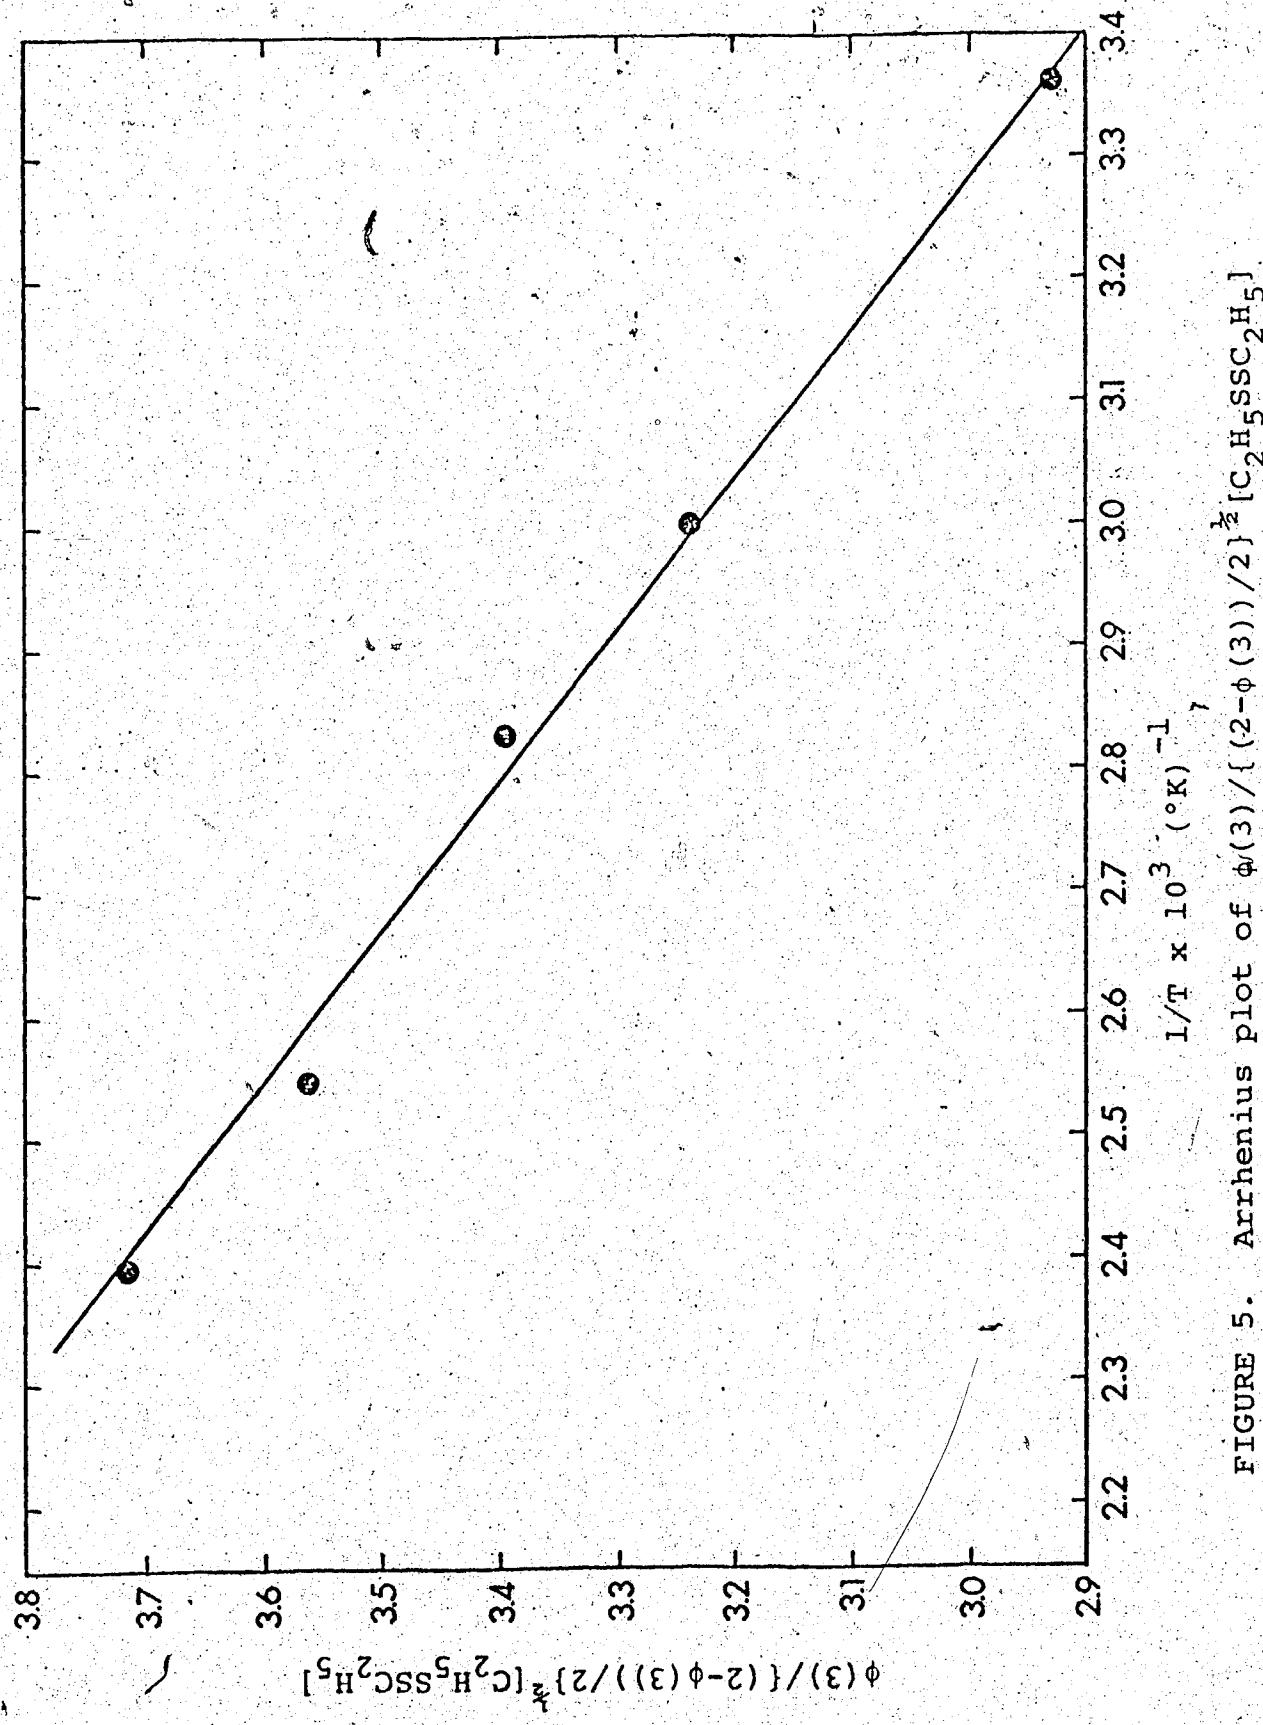

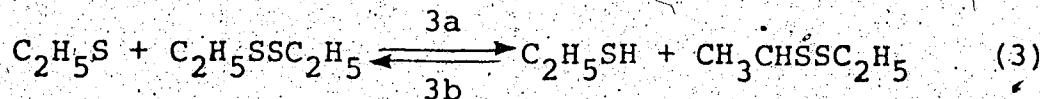

FIGURE 5. Arrhenius plot of  $\phi(3) / \{ (2 - \phi(3)) / 2 \}^{1/2} [C_2H_5SSC_2H_5]$

to  $E_3 = 3.61 \pm 0.09 \text{ kcal mol}^{-1}$ . The methylenic C-H bond dissociation energy in  $\text{C}_2\text{H}_5\text{SSC}_2\text{H}_5$  has not been reported but a reasonable estimate can be made. Thus, because of the adjacent sulfur atom which is expected to stabilize the resulting radical, it is assumed that  $D(\text{methylenic-C-H})$  is close to the tert C-H value,  $90-91 \text{ kcal mol}^{-1}$ .

Then  $\Delta H$  for reaction (3a)

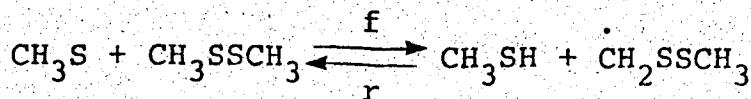

is approximately  $1.5-2.5 \text{ kcal mol}^{-1}$  and hence

$$E_{3b} = 1.6 \pm 0.5 \text{ kcal mol}^{-1}$$

This estimate is the right order of magnitude when compared to the values reported for some radical + thiol reactions,<sup>57b</sup>

In comparison,  $D(\text{C-H})$  for  $\text{CH}_3\text{SSCH}_3$  is  $\sim 95 \text{ kcal mol}^{-1}$ , and  $\Delta H$  for the abstraction reaction

will be approximately  $7 \text{ kcal mol}^{-1}$ . Assuming that the activation energy for the reverse reaction is similar to that for reaction (3b), then the activation energy for the above reaction is approximately  $8.6 \text{ kcal mol}^{-1}$ . This estimate is quite reasonable since hydrogen abstraction from primary C-H bonds by radicals generally features a

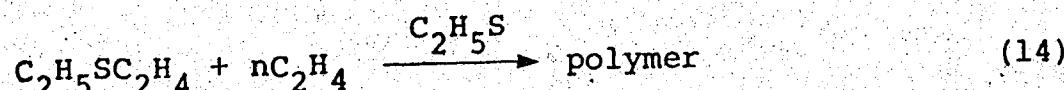

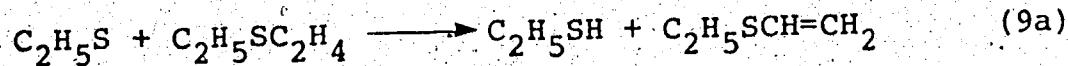

relatively high activation energy, in the range 9-12 kcal mol<sup>-1</sup>.<sup>90</sup>

Recalling that  $k_d/k_c$  for  $\text{CH}_3\text{S}$  = 0.05, the substantially higher value for  $\text{C}_2\text{H}_5\text{S}$ , 0.13, suggests that the activation energy for the disproportionation of  $\text{C}_2\text{H}_5\text{S}$  is lower than that for  $\text{CH}_3\text{S}$  radicals. This may be due to an enhanced stability of the C=S bond upon ethyl substitution or, more likely, to the lower bond dissociation energy of the

$\text{CH}_3\overset{\text{S}}{\underset{\text{H}}{\text{CH}}}-\text{H}$  than the  $\text{H}_2\overset{\text{S}}{\underset{\text{H}}{\text{C}}}-\text{H}$  bond. In any case, comparison with  $k_d/k_c$  = 9.3 and 12.0 for  $\text{CH}_3\text{O}$  and  $\text{C}_2\text{H}_5\text{O}$  radicals,<sup>91</sup> respectively, clearly shows that C-S bonds are not readily converted to C=S bonds.

In the presence of ethylene a complete reaction sequence would consist of steps (1)-(3) and (5)-(14)

Although not all of the products formed could be identified in this system, a careful search failed to reveal the presence of  $\text{C}_2\text{H}_5\text{SCH}=\text{CH}_2$ ,  $\text{C}_2\text{H}_5\text{SC}_4\text{H}_9$  and  $\text{C}_2\text{H}_5\text{SC}_2\text{H}_4\text{SC}_2\text{H}_5$  which would have been formed had steps (7a), (8a), (8c), (9a) and (9c) taken place. The metathetical reaction (12b), postulated by analogy with the  $\text{CH}_3 + \text{CH}_3\text{SSCH}_3$  reaction,<sup>59</sup> is probably relatively

inefficient and can be neglected in the kinetic treatment.

Addition of  $C_2H_5$  to  $C_2H_4$  is a relatively slow process ( $k = 7.5 \times 10^8 \text{ cm}^3 \text{ mol}^{-1} \text{ s}^{-1}$  at  $25^\circ\text{C}$ <sup>92</sup>) compared with other radical-radical reactions taking place in the system and moreover, butene, the expected disproportionation product of  $C_4H_9$  radicals,

was demonstrably absent.

If the suppressing effect of added  $C_2H_4$  on the quantum yield of  $C_2H_5SH$  is denoted by  $f$ , it can be shown (cf Appendix C) that, assuming the steady state concentration of thiyl radicals to vary linearly with that of hydrogen atoms;  $f$  is proportional to the reactive  $C_2H_4$  concentration:

$$f = 1 + \frac{k_5 [C_2H_4]}{k_1 [C_2H_5SSC_2H_5]} \quad V$$

For each  $C_2H_4$  concentration at the various temperatures used in this study  $f$  was determined by iteration such that the following relationship was obeyed:

$$\frac{\phi^\circ(1)}{f} + \frac{\phi^\circ(2a)}{f^2} + \frac{\phi^\circ(3)}{f} = \phi(C_2H_5SH)_{\text{total}} \quad VI.$$

where  $\phi^\circ$  and  $\phi$  are the quantum yields in the absence and presence of  $C_2H_4$ ; respectively. The quantum yields for steps (1), (2a) and (3) calculated in this way are listed in Table XVII.

<sup>a</sup>Photolysis time = 45 min;  $I_a = 1.24 \times 10^{-8}$  einstein min<sup>-1</sup>

$P(H_2) = 580 \pm 10$  Torr;  $P(C_2H_5SSC_2H_5) = 5.00$  Torr.

From Equation VI it follows that

$$\phi(1) + \phi(2a) = \phi^\circ(1)/f + \phi^\circ(2a)/f^2$$

$$= \frac{1}{f} (2.0 + \frac{\phi^\circ(2a)}{f})$$

Substituting f from Equation V and rearranging gives:

$$\frac{1}{1/(\phi(1) + \phi(2a))} = \frac{1}{(2+\beta)} + \frac{1}{(2+\beta)} \frac{k_5 [C_2H_4]}{[C_2H_5SSC_2H_5]} \quad VII$$

where  $\beta = \phi^\circ(2a)/f$ . Although  $\beta$  is somewhat dependent on the ratio  $[C_2H_4]/[C_2H_5SSC_2H_5]$ , plots of Equation VII, illustrated in Figure 6, are linear at the five temperatures studied and, within experimental error, feature a common intercept of 0.48. The least mean square slopes and intercepts are summarized in Table XVIII. The average values of  $\beta$  and  $f$  are 0.08 and 1.5 respectively and therefore  $\phi^\circ(2a) = 0.12$ , in reasonably good agreement with the value of 0.103 derived from the unscavenged system, Table XVI. These results indicate that the assumption whereby  $C_2H_5S$  radical disappear mainly via abstraction, disproportionation and combination reactions is probably correct. The values of  $k_5/k_1$  listed in Table XVIII are plotted in the Arrhenius form in Figure 7, from which

$$\log(k_5/k_1) = (-0.332 \pm 0.023) - (356 \pm 37)/2.3RT$$

Taking the limiting high pressure rate parameters for step (5) as,<sup>89</sup>

$$k_5 = (2.2 \pm 0.4) \times 10^{13} \exp[-(2066 \pm 83)/RT] \text{ cm}^3 \text{ mol}^{-1} \text{ s}^{-1},$$

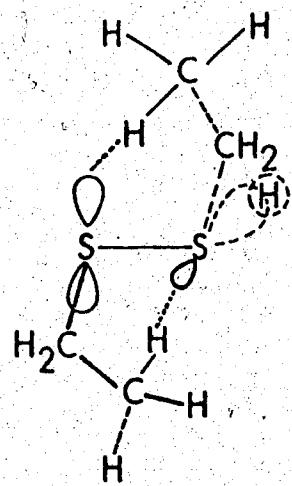

those for step (1) are

$$k_1 = (4.73 \pm 0.64) \times 10^{13} \exp[-(1710 \pm 69)/RT] \text{ cm}^3 \text{ mol}^{-1} \text{ s}^{-1}.$$

The values of the preexponential factor and activation energy are, surprisingly, quite different for the  $\text{H}^+$  +  $\text{CH}_3\text{SSCH}_3$  and  $\text{H} + \text{C}_2\text{H}_5\text{SSC}_2\text{H}_5$  systems, in spite of the fact that the initial step in both reactions involves metathetical displacement of an alkyl thiyl radical. The relative reactivity of these two disulfides towards H atom attack is, however, clearly in line with the observed decrease in reaction rate with decreasing exothermicity in a homologous series. In this case the dimethyldisulfide reaction is considerably faster. From the data in Table II,  $\Delta H = -19.7 \text{ kcal mol}^{-1}$  for the  $\text{H} + \text{C}_2\text{H}_5\text{SSC}_2\text{H}_5$  reaction, compared to  $-21.4 \text{ kcal mol}^{-1}$  for the  $\text{H} + \text{CH}_3\text{SSCH}_3$  reaction and the difference,  $1.7 \text{ kcal mol}^{-1}$ , is in good agreement with the measured activation energy difference of  $1.6 \text{ kcal}$ . Interestingly, the exothermicity difference calculated on the basis of bond strength is  $1.5 \text{ kcal mol}^{-1}$ , indicating that the reactivity of disulfides toward H atom attack is governed mainly by the strengths of the bonds being broken and the new ones formed.

The experimental entropy of activation for the standard state of 1 atm., calculated from the A factor,

is -22.0 e.u., suggesting a somewhat looser transition state relative to that for the  $\text{H} + \text{CH}_3\text{SSCH}_3$  reaction, where  $\Delta S^\ddagger = -26.2$  e.u.  $\Delta S^\ddagger$  can be estimated by Benson's method<sup>77</sup> since the gas phase structural parameters of  $\text{C}_2\text{H}_5\text{SSC}_2\text{H}_5$  are known. Three rotamers of  $\text{C}_2\text{H}_5\text{SSC}_2\text{H}_5$  exist in the gas phase, of which the gauche-gauche conformation is apparently the most stable.<sup>16,93</sup> On the basis of the structural parameters and the spatial conformation of  $\text{C}_2\text{H}_5\text{SSC}_2\text{H}_5$  we conclude that it is possible that one of the H atoms of a terminal methyl group can interact with the non-bonding electrons in the 3p orbital of the second sulfur atom leading to the formation of a five-membered hydrogen-bonded cyclic structure in which there is a barrier to rotation of the other  $\text{C}_2\text{H}_5$  group about the C-S axis. Attack by the H atom on the 3p orbital of the second sulfur atom would result in cleavage of the weak hydrogen

bond, thus allowing free rotation of the ethyl group.

A freely rotating ethyl group contributes about 7.5 e.u.<sup>77</sup> at 300 K and in order to reproduce the experimental activation entropy, -22.0 e.u., the contribution required from the rotation of the ethyl group is:

$$\begin{aligned}
 \Delta S^\ddagger &= S^\ddagger(H \cdot C_2H_5SSC_2H_5) - S^\circ(C_2H_5SSC_2H_5) - S^\circ(H) \\
 &= S^\circ(C_2H_5SSC_2H_5) + R\ln 2 + x - S^\circ(C_2H_5SSC_2H_5) - S^\circ(H) \\
 &= R\ln 2 + x - S^\circ(H) \\
 &= 1.4 + x - 27.4 \\
 &= -26.0 + x \\
 &= -22.0 \text{ e.u.}
 \end{aligned}$$

Therefore,  $x = 26.0 - 22.0$

$$= 4.0 \text{ e.u.}$$

This value, being lower than the full rotational contribution, is reasonable and seems to suggest that the ethyl group rotation is hindered but not fully frozen. This result is in agreement with the proposed gauche-gauche

structure being the most stable conformer of  $C_2H_5SSC_2H_5$ ,<sup>16,93</sup> and with the larger activation energy associated with the

$H + C_2H_5SSC_2H_5$  as compared to the  $H + CH_3SSCH_3$  reaction.

## CHAPTER V

### THE REACTION OF HYDROGEN ATOMS WITH ETHYLMETHYLDISULFIDE

#### Results

##### 1. Products of reaction.

In the gas phase and at room temperature H atoms react with ethylmethyldisulfide to yield  $\text{CH}_3\text{SSCH}_3$ ,  $\text{C}_2\text{H}_5\text{SSC}_2\text{H}_5$ ,  $\text{CH}_3\text{SH}$ ,  $\text{C}_2\text{H}_5\text{SH}$  and, at longer illumination times, sulfur polymer. As will be seen, this system is much more complex than for the case of symmetrical disulfides. Control experiments with a reaction mixture consisting of 580 Torr  $\text{H}_2$  and 2.5 Torr  $\text{CH}_3\text{SSC}_2\text{H}_5$  showed that considerable amounts of  $\text{CH}_3\text{SSCH}_3$  and  $\text{C}_2\text{H}_5\text{SSC}_2\text{H}_5$  were formed by thermal exchange reactions. In subsequent sensitization experiments corrections were made for the thermally produced amounts of these products. It was estimated that less than 5% of the excited mercury atoms were quenched by  $\text{C}_2\text{H}_5\text{SSC}_2\text{H}_5$ .

##### 2. Effects of exposure time, pressure, and temperature.

In the first series of experiments reaction mixtures consisting of 580 Torr  $\text{H}_2$  and 2.50 Torr  $\text{CH}_3\text{SSC}_2\text{H}_5$  were mercury sensitized and the quantum yields for the formation of the thiols and disulfides as a function of exposure time are listed in Table XIX. The quantum yields of formation for both symmetrical disulfides, which are

<sup>a</sup>  $(\text{C}_2\text{H}_5\text{SSCH}_3) = 250 \text{ Torr}$ ,  $P(\text{H}_2) = 580 \text{ Torr}$ ;  $I_a = 1.06 \times 10^{-8} \text{ einstein min}^{-1}$ .

b not measured.

essentially equal in the whole time range, are extremely high initially but decrease sharply with increasing time up to 120 minutes. The time dependence of  $\phi(\text{CH}_3\text{SSCH}_3)$  and of  $\phi(\text{C}_2\text{H}_5\text{SSC}_2\text{H}_5)$  are plotted in Figure 8; extrapolation to zero time gives the value  $\phi(t = 0) = 92$ . As seen from Table XIX the quantum yields of formation of  $\text{CH}_3\text{SH}$  and  $\text{C}_2\text{H}_5\text{SH}$  show only moderate time dependence. The ratio  $\phi(\text{CH}_3\text{SH})/\phi(\text{C}_2\text{H}_5\text{SH})$  is plotted as a function of time in Figure 9. Extrapolation to zero time gives the limiting value of 1.86 which is identical to the rate constant ratio for the  $\text{H} + \text{CH}_3\text{SSCH}_3$  and  $\text{H} + \text{C}_2\text{H}_5\text{SSC}_2\text{H}_5$  reactions.

Next, the quantum yields of the products were examined as a function of substrate pressure. On going from 2.5 Torr  $\text{CH}_3\text{SSC}_2\text{H}_5$  to 5.0 Torr, the quantum yields of  $\text{CH}_3\text{SH}$  and  $\text{C}_2\text{H}_5\text{SH}$  were unchanged while those for  $\text{CH}_3\text{SSCH}_3$  and  $\text{C}_2\text{H}_5\text{SSC}_2\text{H}_5$  increased from 31.7 and 31.3 to 63.5 and 62.8, respectively, i.e., in direct proportion to the pressure increase.

The effect of temperature on the quantum yields of the reaction products was not quantitatively determined because the system was exceedingly complex as a result of the occurrence of thermal exchange reactions. Qualitatively, however, the quantum yields of  $\text{CH}_3\text{SSCH}_3$  and  $\text{C}_2\text{H}_5\text{SSC}_2\text{H}_5$  increased significantly with increasing temperature, while the quantum yields of the thiols increased only moderately.

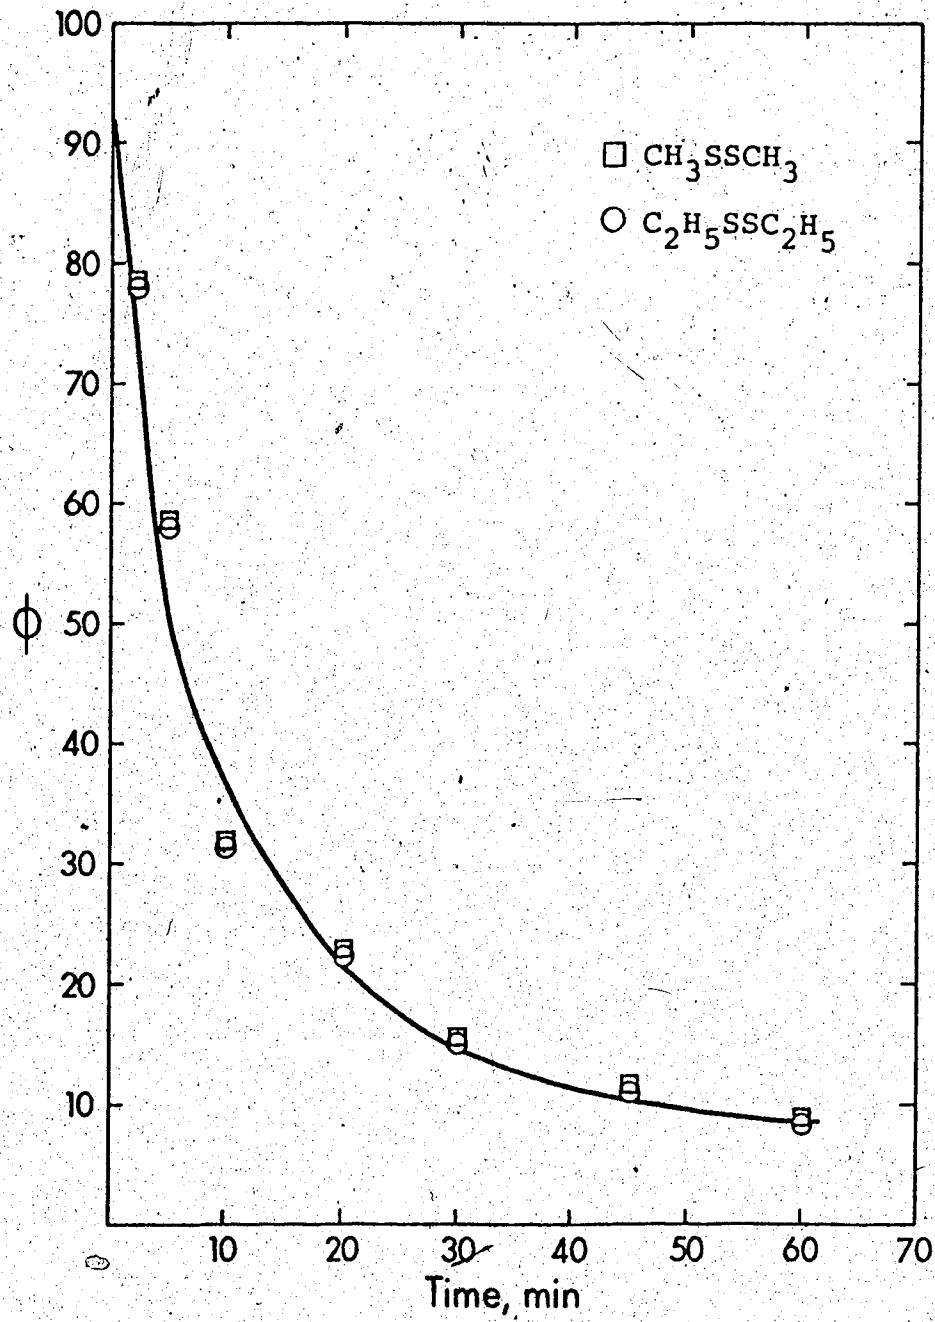

FIGURE 8. Average quantum yields for  $\text{CH}_3\text{SSCH}_3$  and  $\text{C}_2\text{H}_5\text{SSC}_2\text{H}_5$  formation as a function of irradiation time.

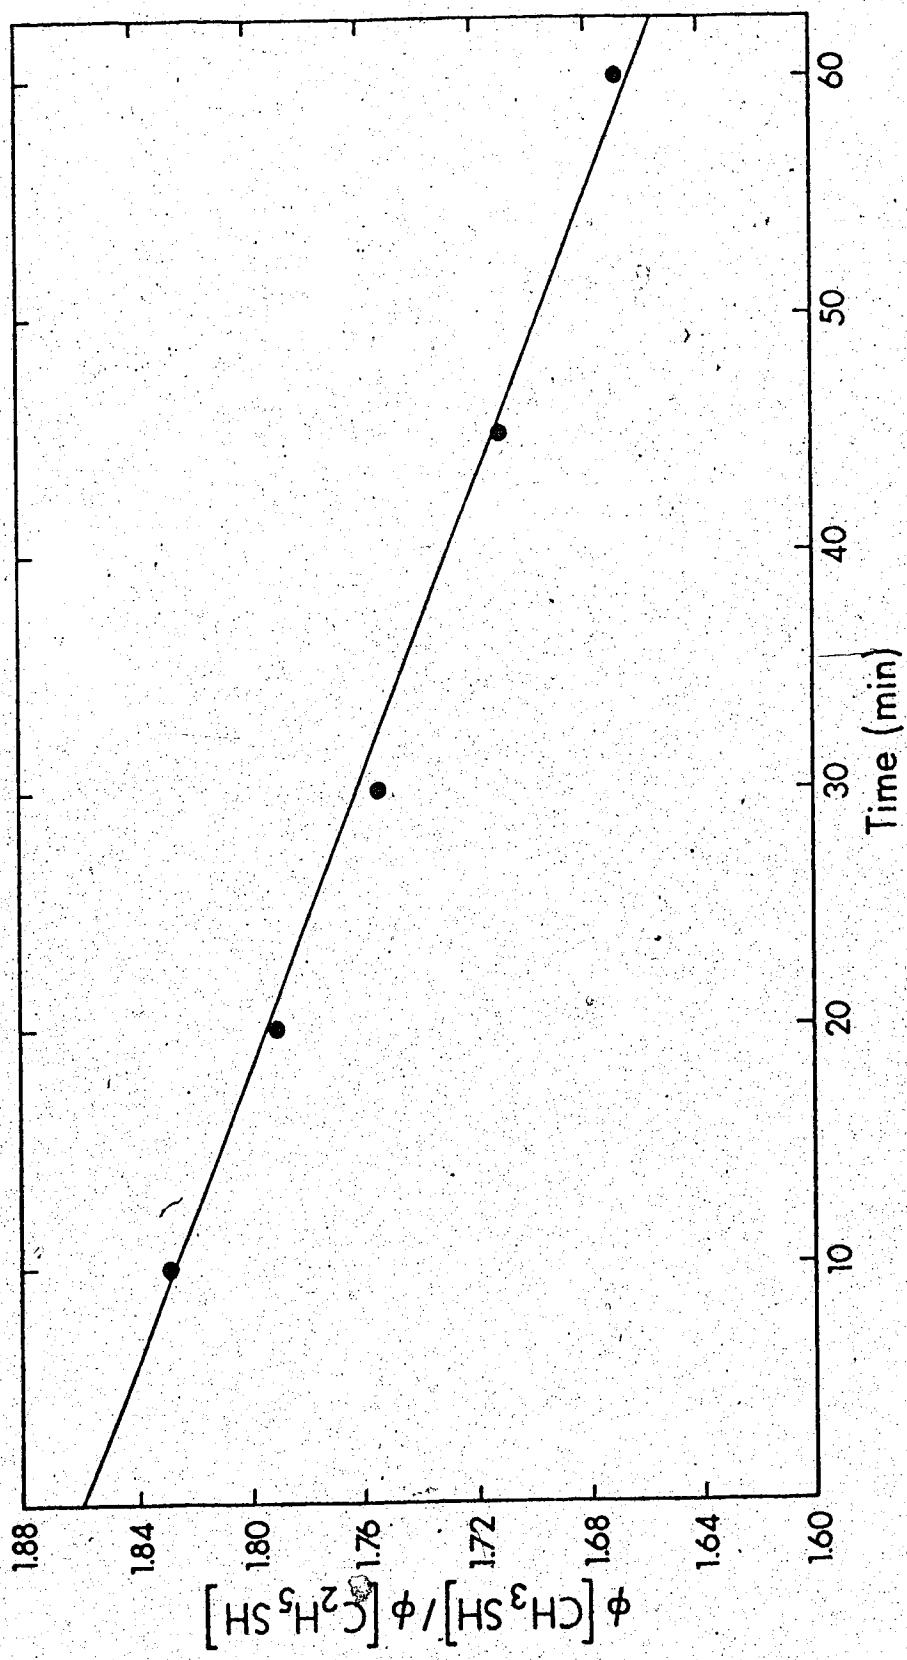

FIGURE 9. Dependence of  $\phi(\text{CH}_3\text{SH})/\phi(\text{C}_2\text{H}_5\text{SH})$  on irradiation time.

### Discussion

The invariance of the thiol quantum yields with  $\text{CH}_3\text{SSC}_2\text{H}_5$  pressure suggests that scavenging of H atoms by the substrate is complete. Hence, and by analogy with the  $\text{H} + \text{CH}_3\text{SSCH}_3$  and  $\text{H} + \text{C}_2\text{H}_5\text{SSC}_2\text{H}_5$  reactions it is proposed that H atoms react with  $\text{CH}_3\text{SSC}_2\text{H}_5$  via two parallel and competing metathetical steps (1) and (2):

The very high initial quantum yields obtained for the formation of  $\text{CH}_3\text{SSCH}_3$  and  $\text{C}_2\text{H}_5\text{SSC}_2\text{H}_5$  indicate that the thiyl radicals generated in reactions (1) and (2) propagate a chain sequence:

Termination of the chain and the final fate of the thiyl radicals is postulated to be combination and disproportionation:

The occurrence of disproportionation is clearly demonstrated by the fact that the sum of the quantum yields of the thiols is 2.2, whereas a value of 2.0 would be expected solely on the basis of reactions (1) and (2).

Because of the occurrence of this chain reaction, the symmetric disulfides accumulate rapidly in the system and their secondary reactions with H atoms also need to be considered in the overall mechanism:

The overall mechanism consisting of the elementary steps (1)-(15) has been tested by computer modeling. The objectives of the simulation were to see if the observed time dependence of the quantum yields can be

reproduced and also to estimate rate constant values for those individual reaction steps which have not been reported in the literature.

The set of differential equations corresponding to the above mechanism was solved numerically by using the algorithm DIFSUB developed by Gear<sup>79</sup> for the numerical integration of a set of stiff ordinary differential equations.

The rate constants  $k_1$  and  $k_2$  were assumed to be identical to those determined for the reactions of H atoms with the corresponding symmetric disulfides,  $\text{CH}_3\text{SSCH}_3$ <sup>94-96</sup> and  $\text{C}_2\text{H}_5\text{SSC}_2\text{H}_5$ ,<sup>97</sup> on the basis of the observation that the extrapolated value of  $\phi(\text{CH}_3\text{SH})/\phi(\text{C}_2\text{H}_5\text{SH})$  at  $t = 0$  is equal to  $k_{14}/k_{15}$ .

The rate constants for the reactions of thiyl radicals with disulfides are not known and values of  $k_3-k_6$  had to be established by fitting the calculated rate of formation for the symmetric disulfides to the measured quantum yields. The equilibrium constant for the disproportionation reaction

has been determined experimentally as being 5.5 at room temperature.<sup>24</sup> If we assume that reactions (3)-(6) approach a similar equilibrium then the corresponding rate constants must satisfy the following relationship:

$$k_4/k_3 \times k_6/k_5 = 5.5 \quad (17)$$

From the set of rate constants used in the simulation listed in Table XX, it is seen that the derived values of  $k_3$  to  $k_6$  conform to this relationship.

It was also considered that the conversion of symmetric disulfides to asymmetric ones should be faster, i.e.,  $k_3 < k_4$  and  $k_5 < k_6$ , because of the contribution to the entropy change from the loss of symmetry. The relative magnitudes of the rate constants  $k_3 - k_6$  are also in line with the observation that substitution of the methyl group on the S atom by ethyl decreases the rate constant<sup>97</sup> for attack by H atoms.

The rate constant for the combination of  $\text{CH}_3\text{S}$  radicals has been reported to be:

$$k_7 = 2.4 \times 10^{13} \text{ cm}^3 \text{ mol}^{-1} \text{ s}^{-1}$$

and we assumed the same value for  $k_9$ , the combination of  $\text{C}_2\text{H}_5\text{S}$  radicals. The  $k_d/k_c$  ratios for  $\text{CH}_3\text{S}$  and  $\text{C}_2\text{H}_5\text{S}$  radicals have been reported<sup>57a, 68</sup> and the rate constants for the cross combination and disproportionation of  $\text{CH}_3\text{S}$  and  $\text{C}_2\text{H}_5\text{S}$  ( $k_{12}$  and  $k_{13}$ ) were taken to be twice as high as for the self reactions ( $k_8$  and  $k_{10}$ ), i.e.,

$$k_{12} = 2k_8 \text{ and } k_{13} = 2k_{10}$$

From Table XX  $k_1/k_2 = 1.86$ ,  $k_3/k_5 = 1.80$  and

TABLE XX  
Rate Constants, ( $\text{cm}^3 \text{ mol}^{-1} \text{ s}^{-1}$ ), Used in the Simulation

<sup>a</sup>Reference 96. <sup>b</sup>Reference 97. <sup>c</sup>Derived from the simulation. <sup>d</sup>Reference 69.

<sup>e</sup>Assumed to be equal to  $k_7$ .

$k_4/k_6 = 1.60$ . The rate constant ratios for disproportionation and combination of thiyl radicals obtained from the simulation,  $k_8/k_7 = 0.08$  for  $\text{CH}_3\text{S}$  and  $k_{10}/k_9 = 0.21$  for  $\text{C}_2\text{H}_5\text{S}$ , are in good agreement with the experimentally derived values of 0.05<sup>57a</sup> and 0.13,<sup>68</sup> respectively.

The simulated time dependence of  $\phi(\text{CH}_3\text{SSCH}_3)$  calculated on the basis of the above mechanism is shown in Figure 10 along with the experimental values (in the whole time range, identical values were obtained for  $\phi(\text{C}_2\text{H}_5\text{SSC}_2\text{H}_5)$ ). Curve A represents the change of the quantum yield with time, and curve B is the average quantum yield calculated from the amount of  $\text{CH}_3\text{SSCH}_3$  formed at the given time. It is seen that curve B follows the experimental trend, reproducing the rapid decline of the quantum yield, and curve A rapidly approaches the value of zero. Both trends are manifestations that the system is approaching equilibrium. The concentrations of the symmetric and asymmetric disulfides calculated at  $t = 20$  minutes correspond to an equilibrium constant of 5.5, in accordance with the assumed rate constants  $k_3-k_6$ .

For  $\phi(\text{CH}_3\text{SH})$  and  $\phi(\text{C}_2\text{H}_5\text{SH})$  the values of 1.41 and 0.79 were obtained, independently of exposure time, in good agreement with the experimental results.

$\phi(\text{CH}_3\text{SSCH}_3)$  calculated in the simulation (Curve B in Figure 10) reproduces satisfactorily the experimentally observed rapid decrease with increasing irradiation time

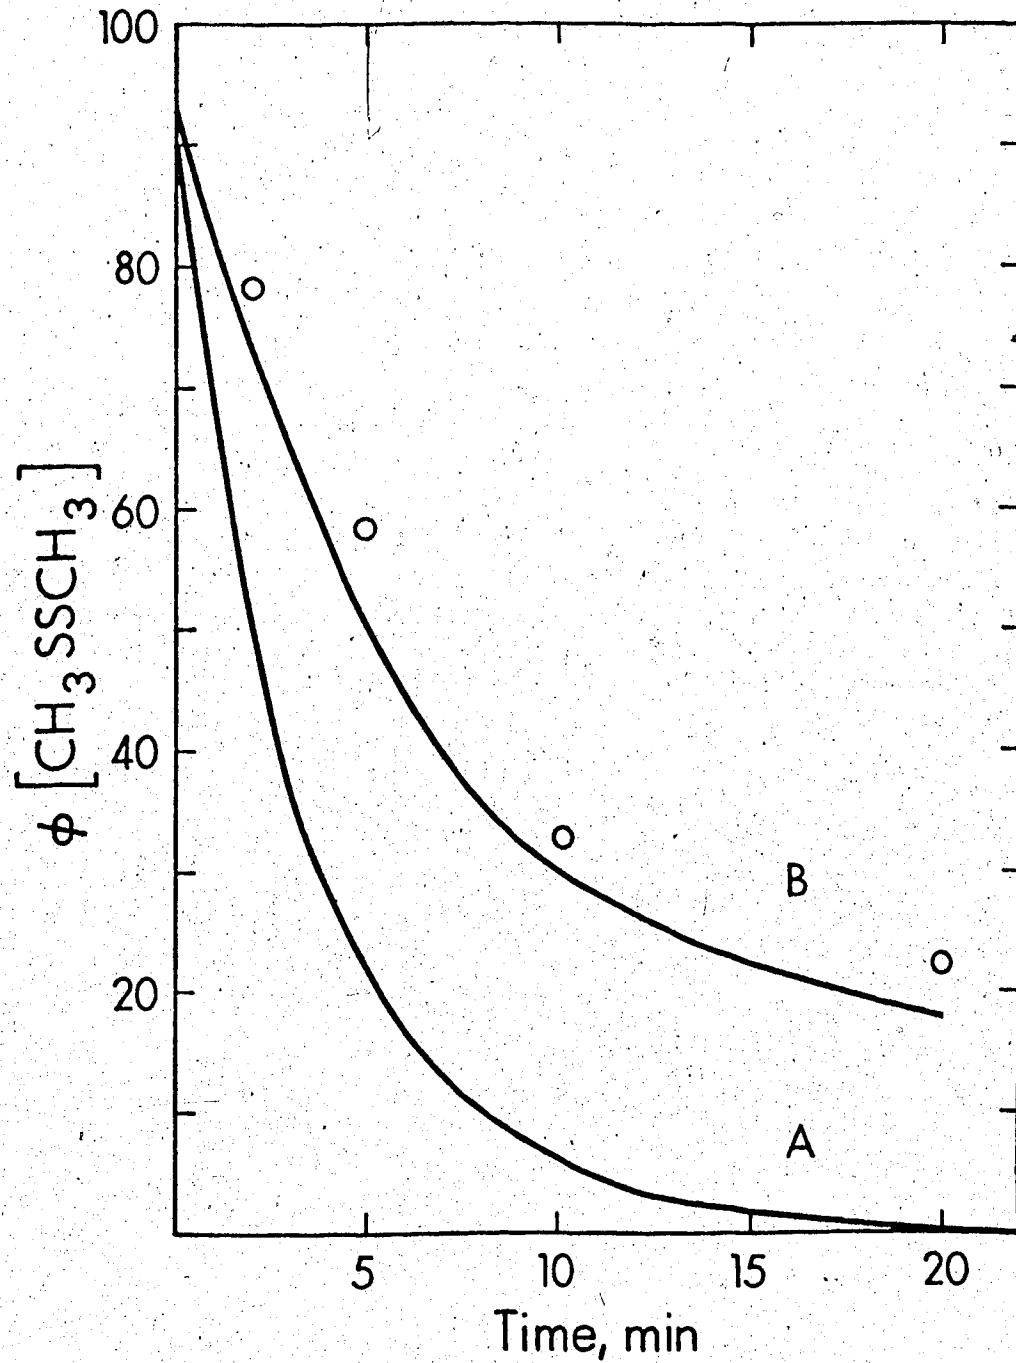

FIGURE 10. Dependence of  $\phi(\text{CH}_3\text{SSCH}_3)$  on irradiation time.

Curve A: instantaneous quantum yield calculated from the amount of  $\text{CH}_3\text{SSCH}_3$  formed in one second;

O: experimental data.

and together with the agreement between the observed and calculated  $\phi(\text{CH}_3\text{SH})$  and  $\phi(\text{C}_2\text{H}_5\text{SH})$  values supports the proposed mechanism. The agreement also shows that the assumed values of the rate constants are reasonable.

The derived rate constants for the reactions of thiyl radicals with disulfides are lower than the corresponding rate constants for H atoms and the difference is probably due to changes in both the preexponential factors and the activation energies. Thus for H atom reactions the gas kinetic collision frequency and the steric factor are both significantly higher than for thiyl radical reactions. Also, hydrogen atom reactions are about 15 kcal mol<sup>-1</sup> more exothermic as compared to the nearly thermoneutral reactions of thiyl radicals.

## CHAPTER VI

### THE REACTIONS OF HYDROGEN ATOMS WITH BIS(TRIFLUOROMETHYL)-DISULFIDE

#### Results

##### 1. Products of the Reaction

The Hg\* photosensitization of a mixture of 600 Torr  $H_2$  and 3.75 Torr  $CF_3SSCF_3$  led to the formation of very small amounts of  $CF_3SCF_3$  (typically, 0.07 umoles for a 45 minute photolysis at 25°C) and extensive deposition of polymer. Subsequent blank experiments however showed that  $CF_3SCF_3$  can be formed from a thermally induced exchange reaction:

The large amounts of polymer indicated that some reaction had taken place, but evidently the products must have been irretrievable. Two primary processes can be envisioned: direct S abstraction,

which would lead to the formation of  $H_2S$  via disproportionation of the HS radicals, and, by analogy with the alkyl disulfides, metathetical displacement:

The small yields of  $\text{CF}_3\text{SCF}_3$  observed suggest that step (2), if it occurs, must be relatively inefficient since this sulfide is fairly stable<sup>98</sup> under the conditions employed here. Nevertheless, the possibility that  $\text{H}_2\text{S}$  undergoes a dark reaction with the substrate had to be explored. To this end, a mixture consisting of 3%  $\text{H}_2\text{S}$  in  $\text{CF}_3\text{SSCF}_3$  was analyzed by gc on an 8 ft porapak N column at 59°C and only the  $\text{CF}_3\text{SSCF}_3$  peak appeared on the chromatogram. As further confirmation, gc analysis of the reaction products formed from the  $\text{Hg}^*$  sensitization of 600 Torr  $\text{H}_2$  in the presence of 3.75 Torr thiirane showed that the  $\text{H}_2\text{S}$  formed in the reaction could in fact be detected with the analytical techniques employed; yet when the experiment was carried out with 3.75 Torr added  $\text{CF}_3\text{SSCF}_3$ , no  $\text{H}_2\text{S}$  was found.

In the light of these results, it was suspected that  $\text{CF}_3\text{SH}$  might also engage in a dark reaction with  $\text{CF}_3\text{SSCF}_3$ . Unfortunately,  $\text{CF}_3\text{SH}$  is not commercially available hence a mixture of  $\text{CH}_3\text{SH}$  (3%) in  $\text{CF}_3\text{SSCF}_3$  was prepared and injected into the gc: as expected,  $\text{CH}_3\text{SH}$  was not eluted on the chromatogram.

In order to test for the intermediacy of thiyl radical in the  $\text{H} + \text{CF}_3\text{SSCF}_3$  reaction a mixture consisting of 2 Torr  $\text{C}_2\text{H}_4$ , 30 Torr  $\text{CF}_3\text{SSCF}_3$  and 600 Torr  $\text{H}_2$  was mercury photosensitized. In addition to  $\text{CF}_3\text{SSCF}_3$ ,  $\text{C}_4\text{H}_{10}$ , and  $\text{C}_2\text{H}_6$ ,  $\text{CF}_3\text{SC}_2\text{H}_5$  was found to be a major product. The

mass spectrum of this compound is given in Appendix B.

The formation of  $\text{CF}_3\text{SC}_2\text{H}_5$  definitely shows that  $\text{CF}_3\text{S}$  radicals are intermediates in the  $\text{H} + \text{CF}_3\text{SSCF}_3$  reaction.

## 2. Effect of added thiirane.

In order to determine the rate coefficient of the  $\text{H} + \text{CF}_3\text{SSCF}_3$  reaction it was decided to carry out competitive studies with added thiirane. Firstly, the  $\text{H} + \text{C}_2\text{H}_4\text{S}$  reaction was investigated as a function of exposure time for a mixture consisting of 600 Torr  $\text{H}_2$  and 3.75 Torr  $\text{C}_2\text{H}_4\text{S}$ . The quantum yields of  $\text{C}_2\text{H}_4$  and  $\text{H}_2\text{S}$  are listed in Table XXI. In this system  $\text{C}_2\text{H}_4$  can be formed in two ways:<sup>38</sup> desulfurization by H atoms, and by S atoms:

From Table XXI, it is seen that  $\phi(\text{C}_2\text{H}_4) = 2.47$  at  $25^\circ$ , independent of exposure time up to 60 minutes. Since  $\phi(\text{H}) = 2.0$ , it follows that  $\phi(6) = 0.47$ . The total quantum yield of ethylene is

$$\phi(\text{C}_2\text{H}_4) = \phi(4) + \phi(6)$$

and since  $\phi(5) = \phi(6)$ , the quantum yield of desulfurization

<sup>b</sup> $\gamma_Y = \phi(C_2H_4) - \phi(H_2S)$

<sup>c</sup>Number of experiments

by H atoms,  $\gamma$ , is then

$$\gamma = \phi(4) = \phi(C_2H_4) - \phi(5) = 2.47 - 0.47 = 2.00$$

at 25°C. The results in Table XXI also show that  $\gamma$  is independent of temperature up to 152°C.

In the presence of 3.75 Torr  $CF_3SSCF_3$ ,  $\phi(C_2H_4)$  decreases and  $H_2S$  is no longer detected. The values of  $\phi(C_2H_4)$  and  $\gamma$  obtained at five different temperatures and  $C_2H_4S$  concentrations are listed in Table XXII.

### Discussion

H atom attack on  $CF_3SSCF_3$  can take place via the following primary processes:

In the absence of measurable amounts of retrievable products it is not possible to make an unequivocal decision with regard to these possibilities, but the results from the

$H_2/CF_3SSCF_3/C_2H_4$  system strongly point to the occurrence of step (3). Thus  $CF_3SCF_3$  is formed in only trace amounts, and is most likely formed from the thermal exchange reaction (1). The occurrence of F abstraction, (7), can be ruled out since a prohibitively high activation

<sup>a</sup> $\gamma = \phi(C_2H_4) - \phi(H_2S)$ ; Photolysis time = 45 min;  $I_a = 1.06 \times 10^{-8}$  einstein min<sup>-1</sup>;  $P(H_2) = 600 \pm 10$  Torr;  $P(CF_3SSCF_3) = 3.75$  Torr.

energy<sup>99</sup> would be associated with this reaction. From these observations, and by analogy with the case of alkyl disulfides, it is therefore concluded that the sole primary process of importance is step (3). The only secondary reaction of importance is probably recombination,

since, owing to the high C-F bond strength, disproportionation cannot take place at the temperatures used in this study.

Strong evidence for the intermediacy of thiyl radicals in this system, and hence in support of step (3), comes from the experiments carried out in the presence of ethylene, where  $\text{C}_2\text{H}_5\text{SCF}_3$  is a major product. The following sequence of elementary reactions accounts for the formation of the observed products:

Since it has been shown that  $\text{CF}_3\text{SH}$  cannot be detected in the presence of large amounts of  $\text{CF}_3\text{SSCF}_3$ , it is very likely that  $\text{CF}_3\text{SH}$  and  $\text{CF}_3\text{SSCF}_3$  exist as a hydrogen bonded complex, e.g.,

Evidence for the existence of a similar complex comes from the results of the photolysis of  $\text{CF}_3\text{COCF}_3$  in the presence of  $\text{H}_2\text{S}$ .<sup>100,101</sup> There was a mass balance deficiency of about 18% for the  $\text{CF}_3$  radicals produced and this was ascribed to the following reaction:

Gc analysis for  $\text{CF}_3\text{SH}$  in the  $\text{CF}_3\text{COCF}_3$  photolyzate however was difficult and the results were inconclusive.<sup>100,101</sup> It is quite likely that in this system as well,  $\text{CF}_3\text{SH}$  forms a hydrogen bond with the substrate.

In the presence of thiirane, the following sequence of reaction steps explains the nature and the quantum yields of the observed products.

The possible occurrence of reaction (16) has to be considered since the following novel metathetical reaction has been shown to take place:<sup>40</sup>

However, kinetic arguments (*vide infra*) indicate that reaction (16) is probably not important in the present system.

Steady state treatment of reactions (3)-(6), and (17) leads to the following kinetic expression:

$$\gamma^{-1} = 0.5 + \frac{k_3[\text{CF}_3\text{SSCF}_3]}{2k_4[\text{C}_2\text{H}_4\text{S}]} \quad I$$

where  $\gamma = \phi(\text{C}_2\text{H}_4) - \phi(5) = \phi(4)$ . The plots of  $\gamma^{-1}$  versus  $[\text{CF}_3\text{SSCF}_3]/[\text{C}_2\text{H}_4\text{S}]$  at the five temperatures examined (Table XXII) shown in Figure 11, are linear and the slope and intercept values obtained by least mean square treatment of the data are given in Table XXIII. The plots

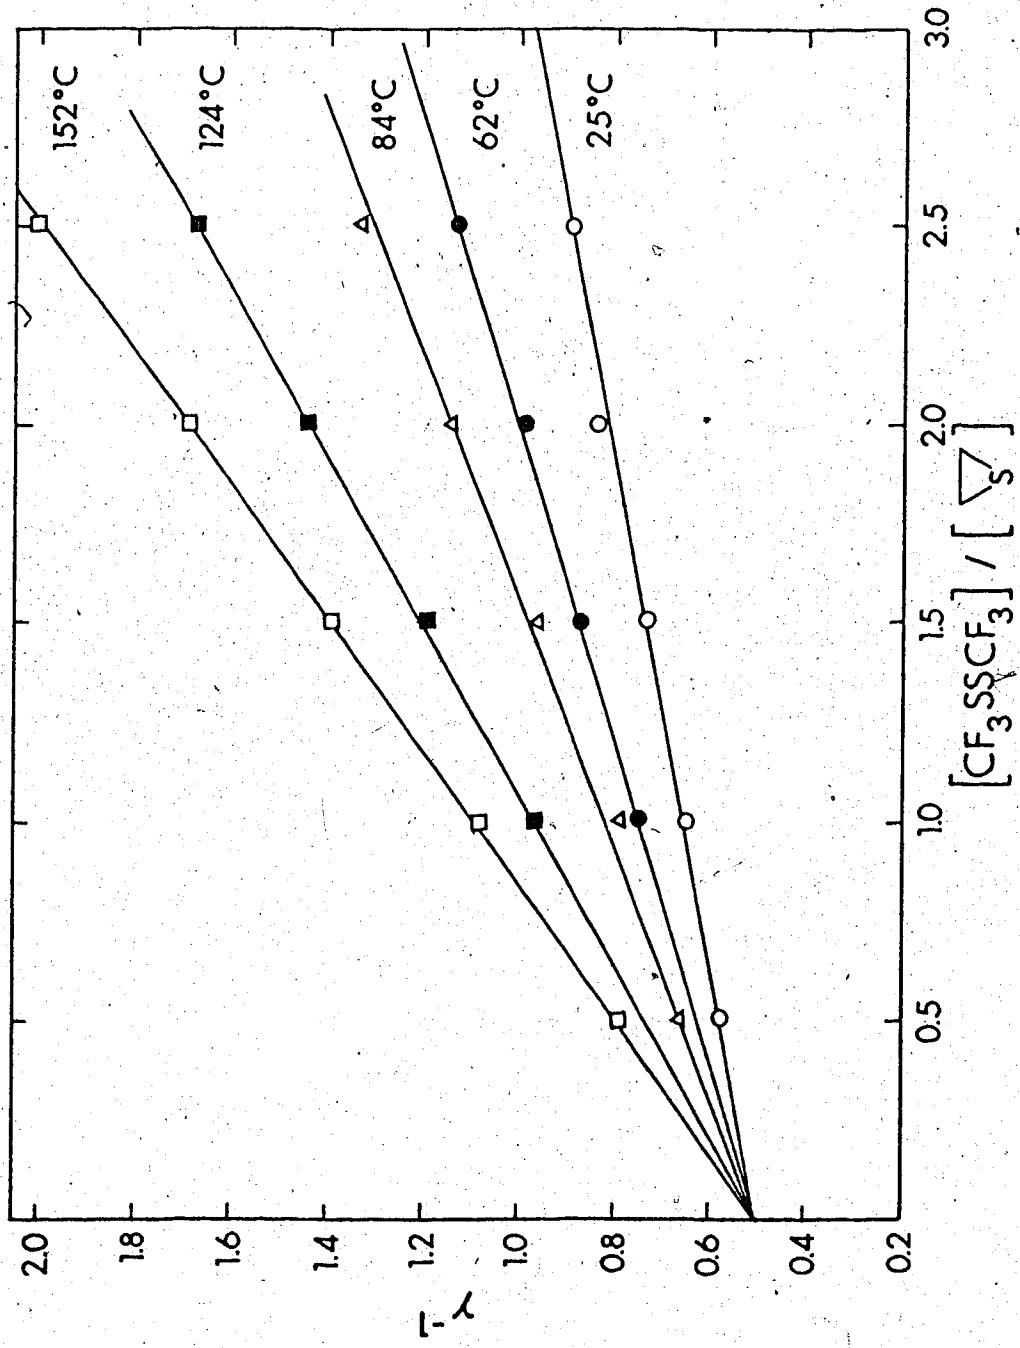

FIGURE 11.  $\gamma^{-1}$  versus  $P[CF_3SSCF_3]/[C_2H_4S]$  at 25, 62, 84, 124 and 152°C.  $P(H_2) = 580 \pm 10$  Torr; photolysis time, 45 minutes.

TABLE XXIII

T, °C	Slope	Intercept	$k_3/k_4$
25	0.163 ± 0.007	0.492 ± 0.0011	0.326 ± 0.014
62	0.245 ± 0.001	0.501 ± 0.001	0.489 ± 0.002
84	0.330 ± 0.010	0.485 ± 0.015	0.659 ± 0.020
124	0.472 ± 0.005	0.496 ± 0.008	0.943 ± 0.010
152	0.601 ± 0.005	0.489 ± 0.007	1.20 ± 0.010

<sup>a</sup>The errors are standard deviations

feature a common intercept close to the value of 0.5 predicted by Equation I, and therefore reaction (16) is probably not important in the overall scheme. The values of  $k_3/k_4$ , also listed in Table XXIII, are plotted in the Arrhenius form in Figure 12, from which

$$\log(k_3/k_4) = (1.41 \pm 0.06) - (2604 \pm 53)/2.3RT$$

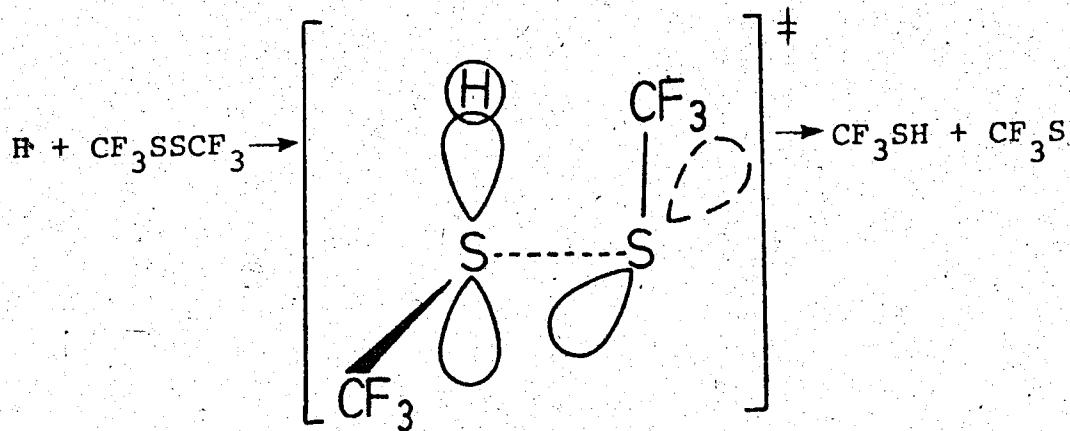

Taking the absolute rate parameters for reaction (4)<sup>102</sup> as

$$k_4 = (1.73 \pm 0.07) \times 10^{13} \exp[-(1880 \pm 24)/RT] \text{cm}^3 \text{mol}^{-1} \text{s}^{-1},$$

those for reaction (3) are:

$$k_3 = (4.45 \pm 0.20) \times 10^{14} \exp[-(4484 \pm 44)/RT] \text{cm}^3 \text{mol}^{-1} \text{s}^{-1}.$$

By analogy with the other H + disulfide systems described above it is proposed that H atom attack takes place exclusively at the sulfur atom, and the complex subsequently decomposes to give trifluoromethanethiol and a trifluoromethylthiyl radical:

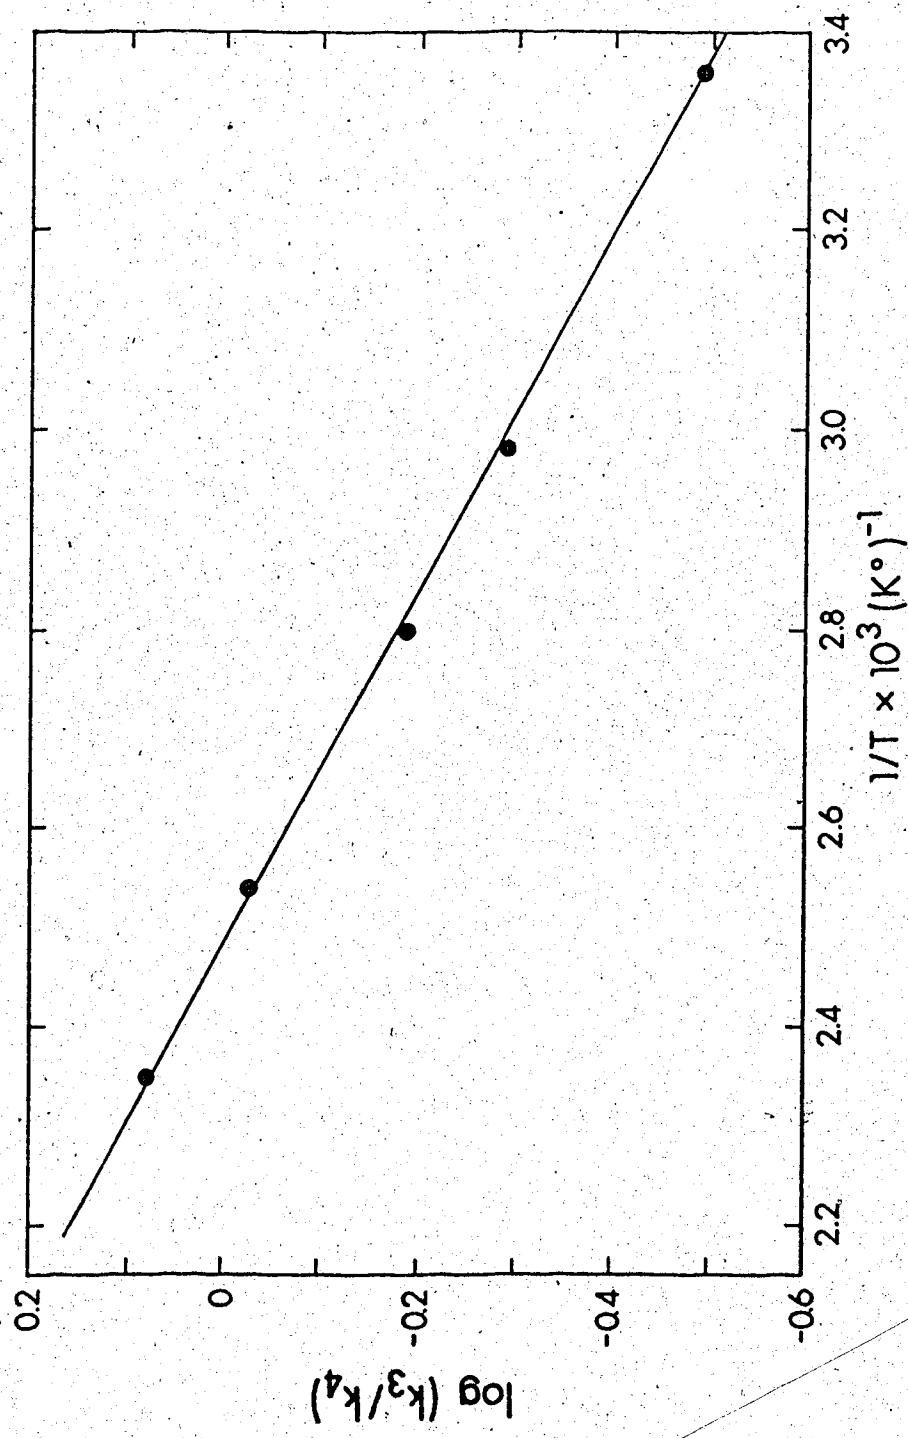

FIGURE 12. Arrhenius plot of  $k_3/k_4$  versus  $1/T$ .

The higher activation energy for the  $\text{H} + \text{CF}_3\text{SSCF}_3$  reaction,  $4.5 \text{ kcal mol}^{-1}$ , as compared to the  $\text{H} + \text{CH}_3\text{SSCH}_3$  reaction,  $0.1 \text{ kcal mol}^{-1}$ , is a clear indication that the strongly electronegative fluorine atoms promote delocalization of the sulfur 3p orbitals. Because of this delocalization it is anticipated that  $\text{CF}_3\text{SSCF}_3$  would not be readily amenable to attack by atoms or radicals less reactive than H atoms.

The experimental entropy of activation for the standard state of 1 atm. calculated from the A factor is  $-17.6 \text{ e.u.}$  This value, as compared to  $\Delta S^\ddagger = -26.2 \text{ e.u.}$  for the  $\text{H} + \text{CH}_3\text{SSCH}_3$  reaction, suggests a looser transition state. This can result from steric hindrance at the sulfur atom by the  $\text{CF}_3$  group, or, more likely, from the contributions of internal modes arising from hindered internal rotations brought about by interactions of lone pairs of electrons of fluorine atoms with the lone pair of the S atom.

## CHAPTER VII

### THE REACTION OF HYDROGEN ATOMS WITH DIETHYLSULFIDE

#### Results

When H atoms are generated by the Hg ( $^3P_1$ ) sensitized decomposition of  $H_2$  in the presence of  $C_2H_5SC_2H_5$ , the observed products are  $C_2H_5SH$ ,  $C_2H_6$ ,  $C_4H_{10}$ ,  $C_2H_4$ ,  $C_2H_5SCHC_2H_5$  (4-methyl-3-thiahexane, MTH),  $C_2H_5SCH(CH_3)CH_3SC_2H_5$  (4,5-dimethyl-3,6-dithiaoctane, DMDTO), and some polymer at longer illumination times.

The sulfur-containing products were identified by comparison of the mass spectra with those of authentic materials, with the exception of DMDTO, the spectrum of which has not been reported. The mass spectrum of this compound is given in Appendix B, along with the major peak assignments. Although DMDTO was relatively volatile, its elution time was very long and consequently the peak was extremely broad and featured considerable tailing. Attempts to quantify the peak areas proved to be quite difficult and inconclusive and hence quantitative measurements were not carried out for this compound.

Control experiments at each temperature in the range 25-188°C showed that  $C_2H_5SC_2H_5$  was thermally stable. The amount of quenching of the excited mercury atoms by

$C_2H_5SC_2H_5$  was estimated to be less than 5% in all the experiments.

### 1. Effects of exposure time and $C_2H_5SC_2H_5$ concentration.

In the first set of runs 580 Torr hydrogen was mercury photosensitized in the presence of 20 Torr  $C_2H_5SC_2H_5$  for various time intervals at 25°C. The results, listed in Table XXIV, show that  $\phi(C_2H_5SH) = 1.53$ , independent of the time of irradiation.

In the next series of experiments the pressure of  $C_2H_5SC_2H_5$  was varied between 1.0 and 30 Torr while keeping the irradiation time constant at 45 minutes. The quantum yields of  $C_2H_5SH$ ,  $C_2H_6$ ,  $C_4H_{10}$ , and  $C_2H_4$  are tabulated in Table XXV, where it is seen that they increase with increasing substrate pressure then level off above 10 Torr  $C_2H_5SC_2H_5$ . In this region H atoms are completely scavenged in the overall reaction.  $\phi(MTH)$  was not measured because its yield at room temperature was negligibly small.

### 2. Effect of temperature.

The mercury sensitization of 580 Torr hydrogen in the presence of various amounts of  $C_2H_5SC_2H_5$  was carried out at 25, 110, 130, 150, 167, and 170°C at a constant exposure time of 45 minutes. The results, tabulated in Table XXVI, show that the yield of ethane increases with increasing temperature, while that of butane decreases, and the ethylene yield shows only moderate temperature

dependence. It is also seen from Table XXVI that the yield of ethanethiol increased from 0.73 to 0.96  $\mu$ moles between 25 and 110°C, after which it remained constant. The yield of MTH becomes measurable at 110°C, then decreases with increasing temperature and finally becomes negligibly small above 167°C.

### 3. Effect of added ethylene.

In the presence of  $C_2H_4$  no additional products were detected but polymer formation was greatly reduced. The quantum yields of  $C_2H_5SH$  from the mercury photosensitization of 10 Torr  $C_2H_5SC_2H_5$  in the presence of increasing amounts of ethylene, at 25, 96, 132, 170, and 188°C, are listed in Table XXVII.  $\phi(C_2H_5SH)$  decreases with increasing ethylene pressure, owing to the competitive scavenging of H atoms by  $C_2H_4$ .

### Discussion

Since the yield of  $C_2H_5SH$  is directly proportional to exposure time, as seen in Table XXIV, this product appears to be of primary origin. By analogy with the  $H + CH_3SCH_3$  reactions then, the initial step is postulated to be

followed by combination and disproportionation of  $C_2H_5$

radicals:

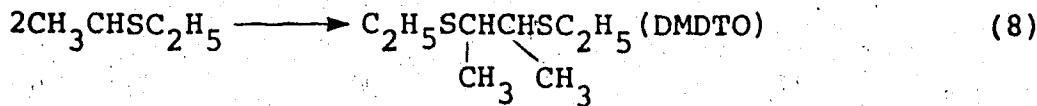

for which  $k_d/k_c$  ratios of  $0.1,^{103} 0.14,^{104}$  and  $0.2^{105}$  have been reported (the latter value is almost certainly too high). If  $\text{C}_2\text{H}_6$  is formed exclusively from step (2), our results (Table XXVI) indicate that  $k_2/k_3 \sim 0.24$  at  $25^\circ$  and increases to 0.58 at  $170^\circ$ . The room temperature value is much too high and moreover, the reported temperature dependence of  $k_d/k_c$  for ethyl radicals is very small.<sup>90</sup> Therefore, an additional  $\text{C}_2\text{H}_6$ -producing reaction must be occurring, i.e., abstraction from the substrate:

The site of abstraction is probably at the methylene moiety since the C-H bond here is weaker ( $\sim 92 \text{ kcal mol}^{-1}$ ) than in the methyl group ( $98 \text{ kcal mol}^{-1}$ ) and moreover, MTH and DMDTO were identified among the products. A complete reaction sequence would then consist of steps (1)-(4) and (5)-(8)

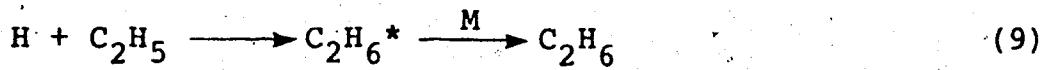

where it is seen that all the products, with the exception of  $\text{C}_2\text{H}_5\text{SH}$ , arise from ethyl radical reactions.

Ethylvinylthioether was not identified as a product. This may be because step (5) is relatively slow, but even if it were formed, gc analysis for ethylvinylthioether in a mixture containing large quantities of  $\text{C}_2\text{H}_5\text{SC}_2\text{H}_5$  would be difficult since both compounds would probably have similar elution times. The disproportionation reactions (5) and (6) are probably inefficient but are included for the sake of completeness.

The only other reaction of ethyl radicals which might be of importance under the conditions employed is:

Although H atoms are completely scavenged in the system above 10 Torr  $\text{C}_2\text{H}_5\text{SC}_2\text{H}_5$  at  $25^\circ$ , the results in Table XXVIII show that scavenging by  $\text{C}_2\text{H}_5\text{SC}_2\text{H}_5$  itself is only complete at  $\geq 110^\circ\text{C}$ . Hence at room temperature an additional H-scavenging reaction, step (9), must be included in the mechanism. Kinetic considerations (*vide infra*) lend support to this conclusion.

The excess energy of  $\text{C}_2\text{H}_6^*$  is about  $97.5 \text{ kcal mol}^{-1}$ <sup>106</sup> and unless collisional stabilization takes place it will

decompose via C-C cleavage,

for which  $A = 1 \times 10^{17} \text{ s}^{-1}$  and  $E_a = 87.4 \text{ kcal mol}^{-1}$ .

From the RRK equation,

$$k_{10} = A \left( \frac{E - E_a}{E} \right)^{s-1}$$

with  $s = 9$ , where  $E$  is the total excess energy,  $E_a$  the critical energy required for decomposition,  $A$  the high pressure A factor, and  $s$  is usually taken to be half the normal modes in the molecule, i.e., 9 for  $\text{C}_2\text{H}_6$ . The decomposition rate constant  $k_{10}$  is calculated to be

$\sim 10^9 \text{ s}^{-1}$ . However, at 580 Torr  $\text{H}_2$   $d_{\text{C}_2\text{H}_6-\text{H}_2}$  can be estimated to be  $6.3^\circ\text{A}$  and since the collisional efficiency of hydrogen is about  $0.2^{106}$  the rate constant for collisional stabilization,

$$k_9 = d_{\text{C}_2\text{H}_6-\text{H}}^2 \times 10^{-19} N \left( \frac{8\pi kT}{\mu} \right)^{1/2} [M]$$

where  $k$  is the Boltzmann constant,  $N$  Avogadro's number,  $\mu$  the reduced mass and  $M$  the concentrations of the deactivating species in moles  $\text{dm}^{-3}$ , is calculated to be  $10^{10} \text{ s}^{-1}$ .

Therefore 91% stabilization will be achieved in the present system. The absence of  $\text{CH}_4$  as a product constitutes additional evidence to the effect that the decomposition

of  $C_2H_6^*$  is probably not significant; moreover,  $\phi(C_2H_6)$  from step (9),  $\phi(9)$ , can be calculated from the relation

$$\phi(9) = \phi_{\text{total}}(C_2H_6) - \phi(C_2H_4) - \phi(4) \quad I$$

and from the results in Table XXVIII it is seen that

$$\phi(9) + \phi(C_2H_5SH) \sim 2.0 \quad II$$

at 25°C, as required by the mechanism, neglecting step (10).

Of all the ethyl radical reactions taking place, reaction (4), H-abstraction from the substrate, is of greatest interest. On the basis of the above mechanism the total rate of ethane formation can be expressed as:

$$R_{C_2H_6} = R_2 + R_4 + R_5 + R_9 \quad III$$

Similarly, the total initial rate of ethylene formation is

$$R_{C_2H_4} = R_2 + R_6 \quad IV$$

and assuming that  $R_5 \sim R_6$ , then

$$R_{C_2H_6} = R_4 + R_{C_2H_4} + R_9 \quad V$$

Since  $R_9 = 0$  for  $T \geq 110^\circ C$ , the values of  $R_4$  can be calculated directly from the  $C_2H_6$  and  $C_2H_4$  yields listed in Table XXVI. For the experiments at 25°  $R_9$  can be calculated using equations (I) and (V). The observed and derived values of  $R_3$  and  $R_4$ , respectively, over the

temperature range examined are listed in Table XXIX

along with those of  $R_4/R_3^{1/2}$ .

The Arrhenius plot of  $R_4/R_3^{1/2}$ , shown in Figure 13, is linear between 25° and 170°C and from the slope,

$E_3/2 - E_4 = -6.9 \pm 0.1 \text{ kcal mol}^{-1}$ . If  $E_3$  is assumed to be zero, then  $E_4 = 6.9 \pm 0.1 \text{ kcal mol}^{-1}$ . This value seems reasonable when compared to those determined for other similar reactions, listed in Table XXX. Hydrogen abstraction from the methylene group of  $C_2H_5SC_2H_5$  by ethyl radicals could be facilitated by the presence of the  $\alpha$ -heteroatom and the rate enhancement as compared to alkane substrates can be explained in terms of stabilization of the incipient radical as a result of electron-releasing conjugative effects of the  $\alpha$ -heteroatom, as shown below:

Comparison between the  $C_2H_5 + C_2H_5SC_2H_5$  and the  $C_2H_5 + C_2H_5OC_2H_5^{107}$  reactions shows that  $E_a$  for the former is considerably less than that for the latter. This is probably due to the greater electron releasing conjugative effects of sulfur, as a consequence of the greater physical size of sulfur and greater availability of the 3p orbital electrons. Similar considerations apply to the  $C_2H_5 + C_2H_5NNC_2H_5^{108}$  and  $C_2H_5 + C_2H_5COCC_2H_5^{103}$  reactions.

TABLE XXX  
Activation Energies for Methylenic Hydrogen Abstraction by  $C_2H_5$  Radicals

Reaction	$E_a$ (kcal mol <sup>-1</sup> )	Temperature Range (°C)	Method	Ref.
$C_2H_5 + C_2H_5OC_2H_5 \rightarrow C_2H_6 + CH_3CHOC_2H_5$	9.0	87-218	γradiolysis	107
$C_2H_5 + C_2H_5COOC_2H_5 \rightarrow C_2H_6 + CH_3CHCOOC_2H_5$	7.3	25-225	Photolysis	103
$C_2H_5 + C_2H_5NNC_2H_5 \rightarrow C_2H_6 + CH_3CHNNC_2H_5$	7.5	30-171	Photolysis	108
$C_2H_5 + C_2H_5SC_2H_5 \rightarrow C_2H_6 + CH_3CHSC_2H_5$	3.4	30-90	Photolysis	109
$C_2H_5 + C_2H_5SC_2H_5 \rightarrow C_2H_6 + CH_3CHSC_2H_5$	6.9	25-170	Hg* sensitization work	This work
$C_2H_5 + CH_3CH_2CH_2CH_2CH_3 \rightarrow C_2H_6 + CH_3CH(CH_2)_3CH_3$	10.1	87-252	Photolysis	110

Our measured value of the activation energy for the  $C_2H_5 + C_2H_5SC_2H_5$  reaction is twice as high as that reported by Knight and Smith<sup>109</sup> from the photolysis of ethylsulfide vapor at 2537°A;

However, since the S-C bond strength in  $C_2H_5SC_2H_5$  is 71 kcal mol<sup>-1</sup><sup>32c</sup>, then at 2537°A, the reaction is exothermic by 41 kcal mol<sup>-1</sup>. If the distribution of this excess energy is proportional to the number of oscillations, then  $E_{C_2H_5} = 28$  and  $E_{C_2H_5S} = 13$  kcal mol<sup>-1</sup> if the energy is localized on the S-C bond and thus the low activation energy determined by them is probably due to the involvement of "hot" ethyl radicals.

$\Delta H$  values for the reactions listed in Table XXXI can be estimated from the methylene C-H bond strengths in  $C_2H_5SC_2H_5$  (~92 kcal mol<sup>-1</sup>),  $C_2H_5OC_2H_5$  (~94.5 kcal mol<sup>-1</sup>) and  $C_6H_{14}$  (~95 kcal mol<sup>-1</sup>), and  $D(C-H) = 97.5$  kcal mol<sup>-1</sup> in  $C_2H_6$ . These are listed in Table XXXI, along with the calculated activation energies for the reverse reactions. The latter appear to be of the right order of magnitude and exhibit a slight downward trend with increasing electrophilicity.

In the presence of ethylene, a complete reaction sequence would then include the competing reaction:

TABLE XXXI  
Heats of Reaction and Activation Energies for Some Metathetical Reactions  
Involving C<sub>2</sub>H<sub>5</sub> Radicals

C <sub>2</sub> H <sub>5</sub> + C <sub>2</sub> H <sub>5</sub> OC <sub>2</sub> H <sub>5</sub> $\xrightleftharpoons[\Sigma]{F}$ C <sub>2</sub> H <sub>6</sub> + CH <sub>3</sub> CHO <sub>2</sub> H <sub>5</sub>	-3.0	9.0	12.0

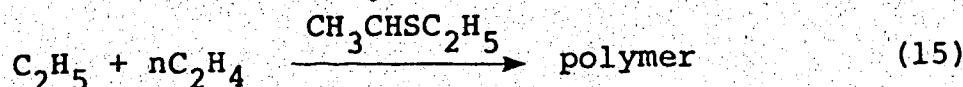

Addition of  $C_2H_5$  to  $C_2H_4$ , step (13),

is a relatively slow process compared with the other radical-radical reactions involving  $C_2H_5$ , i.e., steps (2)-(7), and moreover, butene, the expected disproportionation product of  $C_4H_9$  radicals,

was demonstrably absent. The only remaining possible reaction,

did not seem to be important since polymer formation was greatly reduced in the presence of ethylene. Steady state treatment of steps (1)-(7), (9) and (12) leads to the following rate expression:

$$\phi(C_2H_5SH)^{-1} = \frac{1}{2} \left( 1 + \alpha + \frac{k_{12}[C_2H_4]}{k_1[C_2H_5SC_2H_5]} \right) \quad VI$$

where  $\alpha = R_9/R_1$  and for  $T \geq 110$ ,  $\alpha$  is equal to zero. From the data in Table XXVII, equation VI is plotted in Figure 14. The plots are linear within the temperature range examined and feature a common intercept of 0.5 in the range 96-188°C, Table XXXII. These results substantiate our earlier suggestion that reaction (9) is important

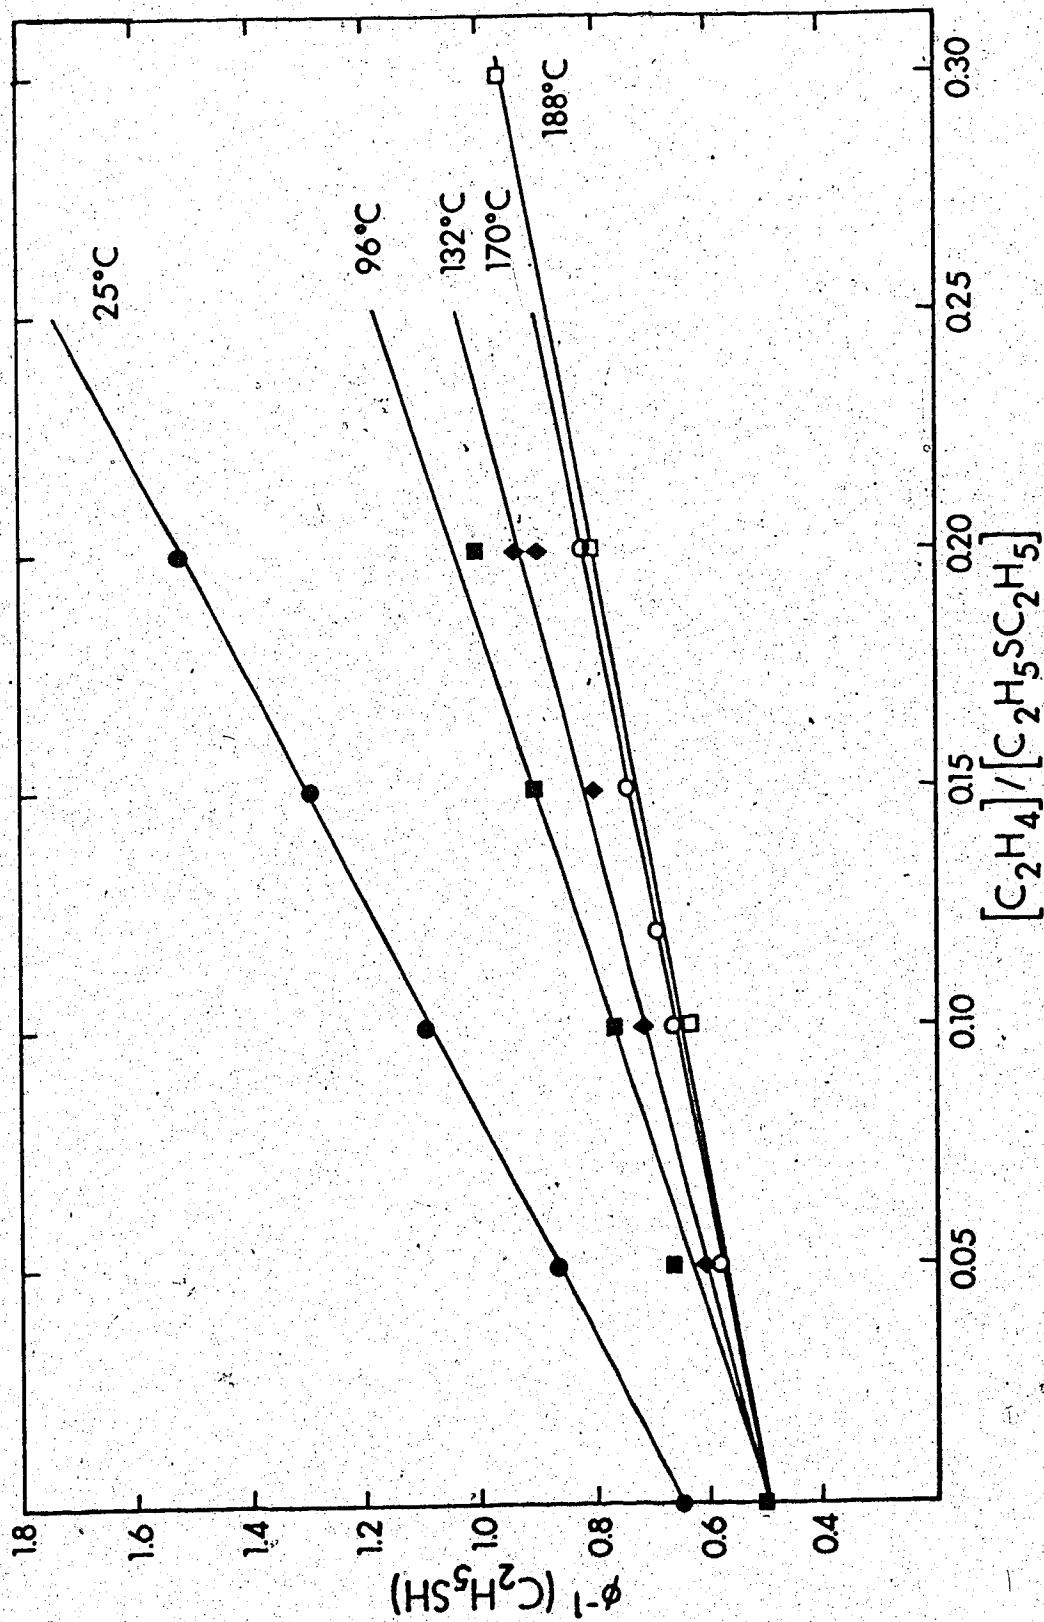

FIGURE 14.  $\phi(C_2H_5SH)^{-1}$  versus  $P[C_2H_4]/P[C_2H_5SC_2H_5]$  at 25,  
96, 132 and 170 and 188°C.

TABLE XXXII  
Slopes and Intercepts of the Plots in Figure 14<sup>a</sup>

T, °C	Slope	Intercept	$k_{16}/k_1$
25	4.31 ± 0.01	0.655 ± 0.001	8.61 ± 0.01
96	2.46 ± 0.10	0.502 ± 0.002	4.92 ± 0.07
132	2.05 ± 0.10	0.502 ± 0.010	4.16 ± 0.07
170	1.59 ± 0.02	0.501 ± 0.002	3.18 ± 0.01
188	1.51 ± 0.10	0.501 ± 0.003	3.02 ± 0.07

<sup>a</sup>The errors are standard deviations.

only at room temperature. At 25°C however the intercept is 0.66 and therefore  $\alpha = 0.32$ , in agreement with the calculated ratio  $\phi(9)/\phi(1) = 0.47/1.53 = 0.31$  using equation I.

The slopes of the plots, listed in Table XXXII, are plotted in the Arrhenius form in Figure 15 from which the value of the rate coefficient ratio is

$$\log(k_{12}/k_1) = -(0.357 \pm 0.035) + (1768 \pm 60)/2.30 RT$$

Accepting Michael and coworkers' value for the limiting high pressure rate parameter for step (12)<sup>89</sup> as

$$k_{12} = (2.2 \pm 0.4) \times 10^{13} \exp[-(2066 \pm 83)/RT] \text{cm}^3 \text{mol}^{-1} \text{s}^{-1}$$

those for step(1) are

$$k_1 = (2.28 \pm 0.4) \times 10^{13} \exp[-(3834 \pm 41)/RT] \text{cm}^3 \text{mol}^{-1} \text{s}^{-1}$$

Of all the substrates examined in the present investigation,  $\text{C}_2\text{H}_5\text{SC}_2\text{H}_5$  would have been the most amenable to abstractive attack, but such does not seem to be the case. Instead, attack appears to take place exclusively at the sulfur atom, and the complex subsequently decomposes to give ethanethiol and an ethyl radical.

The experimental entropy of activation for the standard state of 1 atm, calculated from the A factor, is -23.5 e.u. This value, as compared to  $\Delta S^* = -24.1$  e.u.

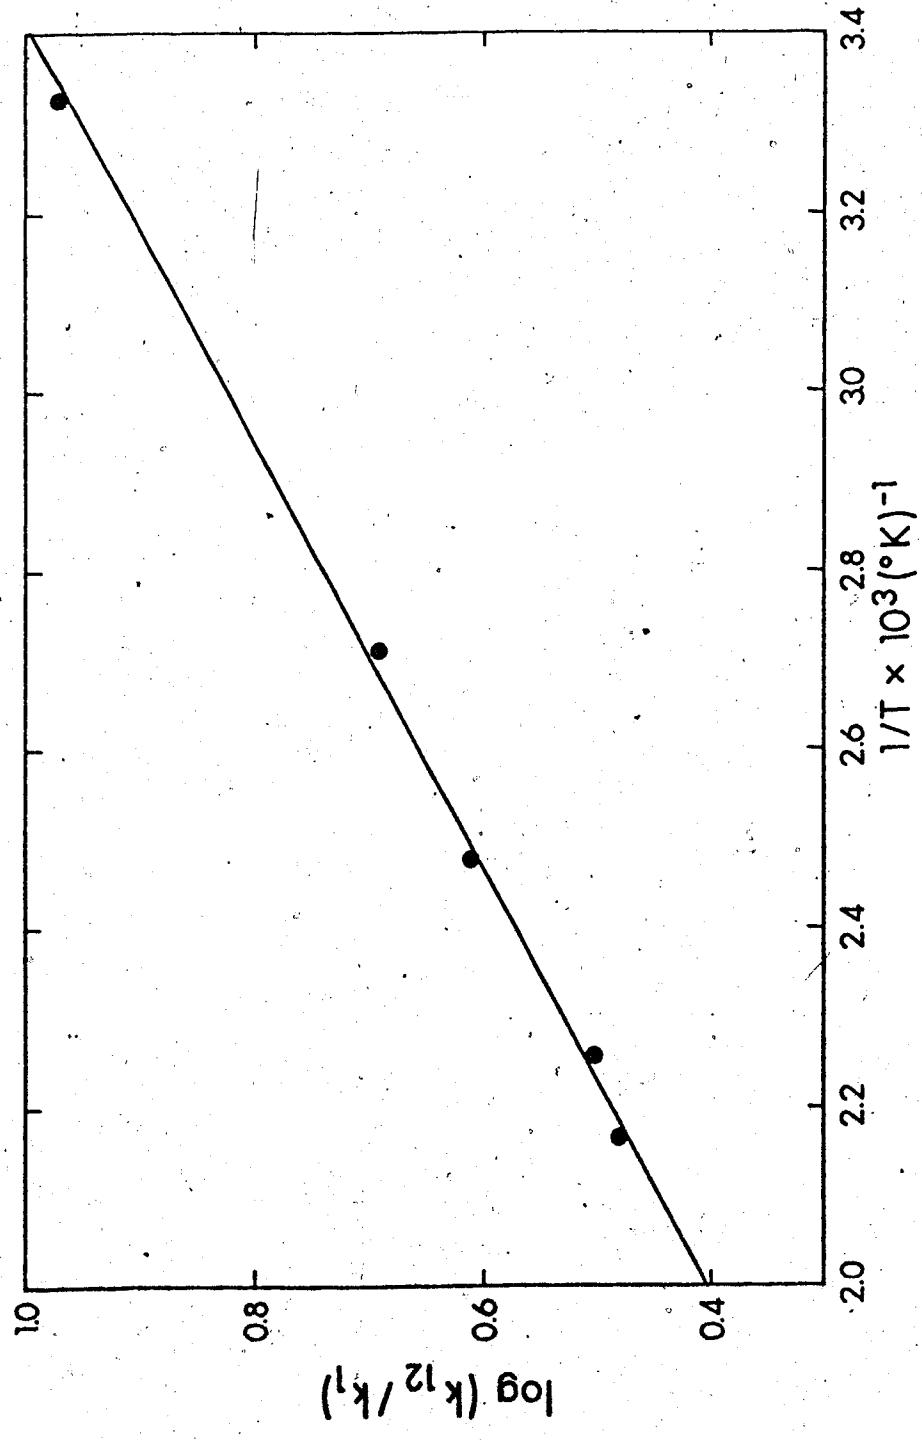

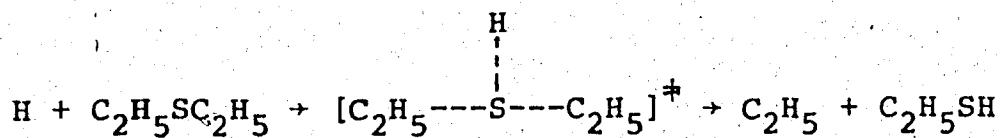

FIGURE 15. Arrhenius plot of  $k_{12}/k_1$  versus  $1/T$ .

for the  $\text{H} + \text{CH}_3\text{SCH}_3$  reaction, suggests that the transition state for the  $\text{H} + \text{C}_2\text{H}_5\text{SC}_2\text{H}_5$  reaction is similar to that of the  $\text{H} + \text{CH}_3\text{SCH}_3$  reaction.

Indeed, the value of the A factor for the  $\text{H} + \text{C}_2\text{H}_5\text{SC}_2\text{H}_5$  reaction can be reproduced by assuming a transition state similar to that proposed for the  $\text{H} + \text{CH}_3\text{SCH}_3$  system,<sup>40</sup>

which involves an initial interaction between the H atom and the non-bonding 3p orbital of the sulfur atom.

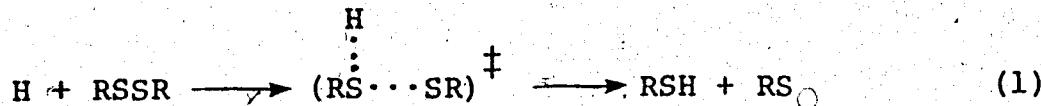

The higher activation energy for the  $\text{H} + \text{C}_2\text{H}_5\text{SC}_2\text{H}_5$  reaction,  $3.8 \text{ kcal mol}^{-1}$ , as compared to the  $\text{H} + \text{CH}_3\text{SCH}_3$  reaction,  $2.6 \text{ kcal mol}^{-1}$ , is a clear indication that the C-S bond in  $\text{C}_2\text{H}_5\text{SC}_2\text{H}_5$  is stronger than that in the  $\text{CH}_3\text{SCH}_3$ : indeed, values of 71 and  $70 \text{ kcal mol}^{-1}$ , respectively, have been reported.<sup>32c</sup> This is probably due to the greater hyperconjugative effects of methylene hydrogens in the ethyl group.

## CHAPTER VIII

### SUMMARY AND CONCLUSIONS

The gas phase reactions of hydrogen atoms, generated by the  $Hg(^3P_1)$  sensitization of hydrogen, with dimethyl-disulfide, diethyldisulfide, ethylmethyldisulfide, bis(trifluoromethyl)disulfide and diethylsulfide have been examined at room and moderately elevated temperatures.

With dialkyldisulfides, thiols are the only retrievable products and solid polymer formation was observed. From the effects of exposure time, light intensity and concentration, it is concluded that H atoms attack disulfides exclusively at one of the sulfur atoms, thereby displacing a thiyl radical:

Hydrogen abstraction, even from the relatively weak methylenic C-H of  $C_2H_5SSC_2H_5$  appears to be an unimportant process. In the presence of ethylene, compounds of the type,  $CH_3SC_2H_5$  and  $C_2H_5SC_2H_5$  were found to be major products, a clear indication of the intermediacy of thiyl radicals in these systems.

With the unsymmetrical disulfide,  $CH_3SSC_2H_5$ , formation of  $CH_3SSCH_3$  and  $C_2H_5SSC_2H_5$  were observed in high yields along with  $CH_3SH$  and  $C_2H_5SH$ . These are formed in a chain

reaction involving metathetical  $C_2H_5S$  and  $CH_3S$  displacement reactions. The initial ratio of the quantum yields  $\phi(CH_3SH)/\phi(C_2H_5SH)$  is 1.86, identical to the rate constant for the  $H + CH_3SSCH_3$  and  $H + C_2H_5SSC_2H_5$  reactions.

Polymerization is the only observable result of the  $H + CF_3SSCF_3$  reaction. However, it was shown that  $CF_3SH$ , the expected primary product, cannot be detected in the presence of  $CF_3SSCF_3$ , possibly because of strong hydrogen bonding associations. That reaction had taken place was deduced from the following observations:

1. polymer formation was apparent.
2. in competitive experiments with  $C_2H_4S$ , the  $C_2H_4$  yields from the  $H + C_2H_4S$  reaction decreased with increasing  $CF_3SSCF_3$  concentration.
3. in the presence of  $C_2H_4$ ,  $CF_3SC_2H_5$  was found to be a major product, pointing to the intermediacy of  $CF_3S$  radicals.

By analogy with the other  $H +$  disulfide reactions studied here, and since F abstraction requires a very high activation energy, it is concluded that the primary process in the  $H + CF_3SSCF_3$  reaction is also a metathetical displacement reaction, i.e., (1).

Although the  $H + RSSR$  reactions ( $R = CH_3, C_2H_5, CF_3$ ) feature a common primary process, some differences are apparent in the ensuing secondary reactions.

For the  $H + CH_3SSCH_3$  reaction  $\phi(CH_3SH) = 2.1$ , independent of temperature up to  $120^\circ$ . Thus, the following simple mechanism applies

and abstraction from the substrate,

is apparently not important. On the basis of thermochemical considerations it can be estimated that  $E_5 \sim 8.6 \text{ kcal mol}^{-1}$  and hence this reaction cannot compete with disproportionation and combination, both of which proceed with very little or no activation energy. From the reported value of  $k_3/k_4 \sim 0.05$ ,  $\phi(2) \sim 2.0$ , as required by the mechanism.

With diethyldisulfide however,  $\phi(C_2H_5SH)$  varies from 2.32 at  $25^\circ$  to 2.84 at  $145^\circ\text{C}$ . Since, by analogy with  $CH_3S$  radicals, the rate of disproportionation of  $C_2H_5S$  radicals should be temperature independent, this can only mean that the abstractive route to thiol formation is operative. The major reactions occurring are then

From the reported value of  $k_7/k_8 = 0.13$ , the quantum yield for reaction (9) could be calculated at each temperature and from kinetic analysis of the results,  $E_9 \sim 3.6 \text{ kcal mol}^{-1}$ . This is substantially lower than that estimated for abstraction from  $\text{CH}_3\text{SSCH}_3$  by  $\text{CH}_3\text{S}$  radicals and hence in this system reaction (9) can compete with reactions (7) and (8).

The  $\text{H} + \text{C}_2\text{H}_5\text{SSCH}_3$  reaction proved to be more complex since, in addition to disproportionation, combination and hydrogen abstraction, the  $\text{CH}_3\text{S}$  and  $\text{C}_2\text{H}_5\text{S}$  radicals generated in the primary process undergo thiyl radical displacement reactions with the substrate, thus generating a long chain:

Chain termination was assumed to take place via radical-radical combination and disproportionation. The quantum yields of the symmetrical disulfides were equal and time dependent, the extrapolated value at zero exposure time being 92. Those for  $\text{CH}_3\text{SH}$  and  $\text{C}_2\text{H}_5\text{SH}$  changed only

moderately with time and  $\phi(\text{CH}_3\text{SH})/\phi(\text{C}_2\text{H}_5\text{SH})$  at  $t = 0$  was

1.86. A mechanism consisting of 15 elementary steps was tested by computer modeling using the algorithm DIFSUB.<sup>111</sup>

Although rate constants for the reactions of thiyl radicals with alkyldisulfides are not known, reasonable estimates could be arrived at such that the simulated variation in  $\phi(\text{CH}_3\text{SSCH}_3)$  was in good agreement with the experimentally observed trend.

The  $\text{H} + \text{C}_2\text{H}_5\text{SC}_2\text{H}_5$  system was also investigated, not only in order to complement the  $\text{H} + \text{CH}_3\text{SCH}_3$  reaction examined recently, but to ascertain whether higher alkyl substituents might render hydrogen abstraction more competitive. No evidence, however could be adduced for the occurrence of this reaction and the only primary process of significance is ethyl radical displacement.

The various ensuing reactions of  $\text{C}_2\text{H}_5$  radicals confer some complexity on this system. Thus, in addition to combination and disproportionation,  $\text{C}_2\text{H}_5$  abstracts from the substrate, probably at the methylenic site:

and a complete mechanism featuring disproportionation and combination of  $\text{C}_2\text{H}_5$  and  $\text{C}_2\text{H}_4\text{SC}_2\text{H}_5$  radicals was

considered. It was also observed that the  $\text{H} + \text{C}_2\text{H}_5$  combination reaction is important at room temperature.

From kinetic analysis of the results  $E_{13}$  was found to have the value  $6.9 \pm 0.1 \text{ kcal mol}^{-1}$ . This value is quite low compared to abstraction from other methylenic sites by  $\text{C}_2\text{H}_5$  radicals and is believed to be a consequence of enhanced stabilization of the incipient radical due to the superior conjugation properties of sulfur.

Arrhenius parameters for the  $\text{H} + \text{CH}_3\text{SSCH}_3$ ,  $\text{C}_2\text{H}_5\text{SSCH}_3$  and  $\text{C}_2\text{H}_5\text{SC}_2\text{H}_5$  reactions were determined in competitive experiments employing  $\text{C}_2\text{H}_4$ , since the rate parameters for the competing reaction:

have been well established. For the  $\text{H} + \text{CF}_3\text{SSCF}_3$  system the reference was the  $\text{H} +$  thirane reaction:

The resulting activation energies and A factors are summarized in Table XXXIII, along with the exothermicities for the overall reactions, calculated from the data in Table II. Corresponding values for the  $\text{H} + \text{COS}$ ,  $\text{C}_2\text{H}_4\text{S}$  and  $\text{CH}_3\text{SCH}_3$  reactions are also included for the sake of comparison.

Many years ago, Evans and Polanyi<sup>112</sup> noted that, for exothermic reactions of Na atoms and  $\text{CH}_3$  radicals

<sup>b</sup>Average value estimated from  $\Delta H_f^\circ$  values for H +  $\text{CH}_3\text{SSCH}_3$

and  $\text{C}_2\text{H}_5\text{SSC}_2\text{H}_5$ .

with a homologous series of molecules, an empirical relationship of the form

$$E_a = A + \alpha \Delta H$$

was often obeyed. Semenov<sup>113</sup> showed that the reactions of H, D and OH with selected classes of compounds also follow this trend. Typically, values of  $\alpha$  range between 0.2 and 0.4, and the A values only differed by a small amount, 10-15 kcal, among the various atoms and radicals examined. Hence, for the cases examined, the predominant factor governing the magnitude of  $E_a$  is  $\Delta H$ .

The plot of  $E_a$  versus  $\Delta H$  for the  $H + COS$ ,  $C_2H_4S$ ,  $CH_3SCH_3$ ,  $C_2H_5SC_2H_5$ ,  $CH_3SSCH_3$  and  $C_2H_5SSC_2H_5$  reactions, is illustrated in Figure 16. The alkyl sulfides and disulfides follow a linear relationship of the form

$$E_a = 0.9 \Delta H + 19.36 \text{ kcal mol}^{-1}$$

from which  $E_a$  for the  $H + C_2H_5SSCH_3$  reaction is predicted to be  $0.9-1.4 \text{ kcal mol}^{-1}$ . This is a reasonable value, being intermediate between those for the corresponding symmetrical disulfides.  $COS$  and  $C_2H_4S$  do not follow the above trend, as expected, since desulfurization takes place with these substrates. For  $H + CF_3SSCF_3$  reaction with  $E_a = 4.5 \text{ kcal mol}^{-1}$ , if H atom is assumed to attack S atom, then  $\Delta H \sim 16.5 \text{ kcal mol}^{-1}$ .

The experimental entropies of activation, calculated from the A factors, also listed in Table XXXIII, are

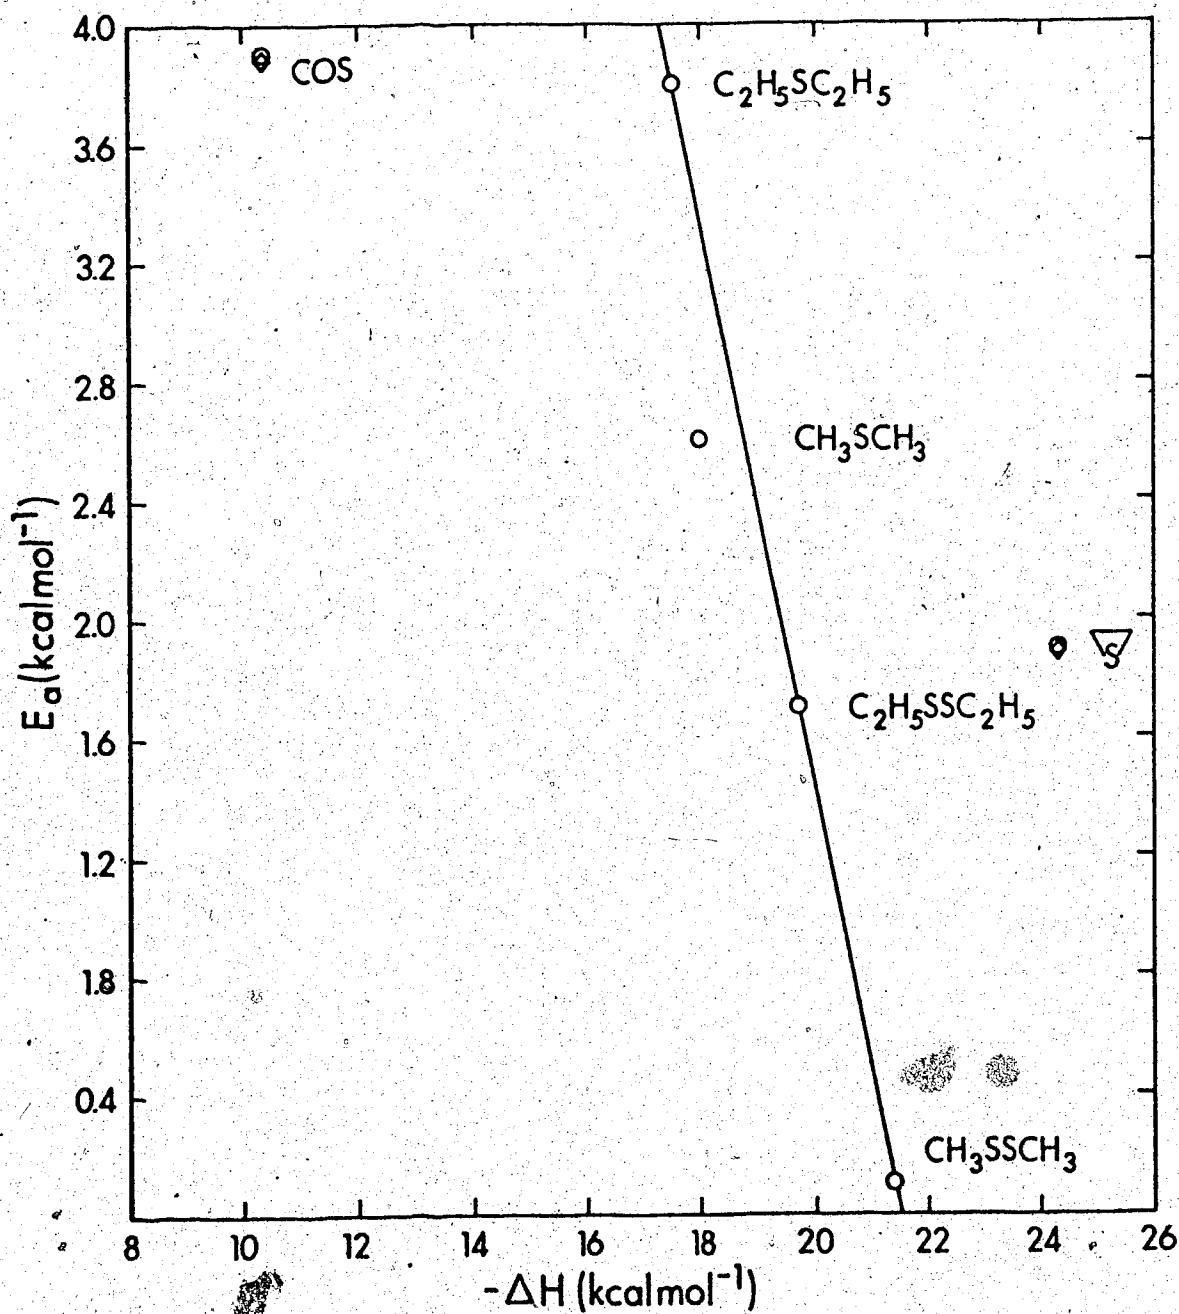

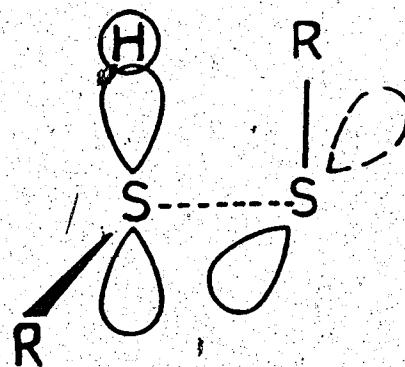

FIGURE 16. Plot of an empirical relationship for activation energies:  $E_a = 0.9\Delta H + 19.36$  for the reaction series  $\text{H} + \text{CH}_3\text{SSCH}_3$ ,  $\text{C}_2\text{H}_5\text{SSC}_2\text{H}_5$ ,  $\text{CH}_3\text{SCH}_3$  and  $\text{C}_2\text{H}_5\text{SC}_2\text{H}_5$ .

consistently high and negative, suggesting a "tight" transition state. It was shown that good agreement could be obtained between the experimental and calculated entropies of activation if the transition state was assumed to be a rigid complex wherein H attacks the sulfur lone pair orbital, e.g.,

~~For the case of  $C_2H_5SSC_2H_5$  and  $CF_3SSCF_3$  hindered internal rotations give rise to additional contributions to the entropy; in the former, this is probably due to the possibility of hydrogen bonding with one of the S 3p orbitals in the gauche-gauche conformation and in the latter, to interactions between the lone pairs of electrons on the fluorine and sulfur atoms.~~

The activation energies associated with the  $H +$  alkylsulfide reactions are somewhat higher than those required by the  $H +$  alkyldisulfide reactions and this is entirely due to the difference between the C-S and S-S bond strengths. On the other hand,  $E_a$  for the  $CF_3SSCF_3$  reaction is substantially higher and this is

undoubtedly due to delocalization of the 3p sulfur orbitals by the electron-withdrawing fluorine atoms.

The room temperature rate constants for the reactions of H, O, S, OH,  $\text{CH}_3$ ,  $\text{CF}_3$ ,  $\text{CH}_3\text{S}$  and  $\text{C}_2\text{H}_5$  with sulfides and disulfides are summarized in Table XXXIV and the Arrhenius parameters, where available, in Table XXXV. Although the data available to date are rather limited, some interesting features are worthy of note.

Firstly, OH radicals appear to be the most reactive of the species examined. This is not unusual however since the primary process is electron transfer, which is known to be rapid.

Oxygen and sulfur atoms appear to be more reactive than hydrogen atoms and the low and, for oxygen, occasionally negative activation energies associated with attack on  $\text{C}_2\text{H}_4\text{S}$  and  $\text{CH}_3\text{SCH}_3$ , Table XXXV, point to the electrophilic nature of the interaction. The values for  $\text{CH}_3\text{S}$  and  $\text{C}_2\text{H}_5\text{S}$  radicals, derived from the simulations, are approximately two orders of magnitude lower than those for hydrogen atoms and this may be due to delocalization of the unpaired orbital. The data available to date indicate that  $\text{CH}_3$  radical attack at the sulfur atom of organosulfur molecules is very slow: The most reasonable explanation for this is a thermochemical one, i.e., the new C-S bond formed in the  $\text{CH}_3 + \text{CH}_3\text{SSCH}_3$  reaction

<sup>a</sup>For attack on sulfur; A in cm<sup>3</sup> mol<sup>-1</sup> s<sup>-1</sup> and E<sub>a</sub> in kcal mol<sup>-1</sup>; <sup>b</sup>Ref. 37; <sup>c</sup>Ref. 38;<sup>d</sup>Ref. 40; <sup>e</sup>This work; <sup>f</sup>Ref. 115; <sup>g</sup>Ref. 48; <sup>h</sup>Ref. 53; <sup>i</sup>Ref. 54.

is considerably weaker than the S-H bond formed in the  $\text{H} + \text{CH}_3\text{SSCH}_3$  reaction, thus lowering the exothermicity.

The present results provide a rationale for the well documented observation that hydrodesulfurization of petroleums produces large quantities of volatile, sulfur-containing material. It is hoped that future studies will be directed towards the elucidation of the reactions of hydrogen atoms with thiophenic substrates in order to set up a suitable data base for computer simulation of this vital yet little understood process.

## APPENDIX A

### Competitive Quenching Correction

When mercury photosensitization experiments are carried out in the presence of more than one substrate, the amount of quenching by each substrate can be readily calculated, as shown in the following example for the  $H_2-C_2H_4$  case.

From simple collision theory, the quenching rate constants for the quenching of  $H_2$  and  $C_2H_4$  are:

$$k_{H_2} = \sigma_{H_2}^2 \left[ \frac{8\pi RT}{M_{Hg} M_{H_2}} \left( \frac{M_{Hg} + M_{H_2}}{M_{Hg} M_{H_2}} \right) \right]^{1/2} \quad I$$

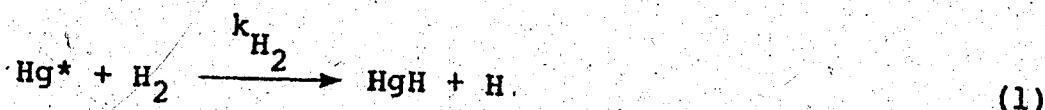

$$\text{and } k_{C_2H_4} = \sigma_{C_2H_4}^2 \left[ \frac{8\pi RT}{M_{Hg} M_{C_2H_4}} \left( \frac{M_{Hg} + M_{C_2H_4}}{M_{Hg} M_{C_2H_4}} \right) \right]^{1/2} \quad II$$

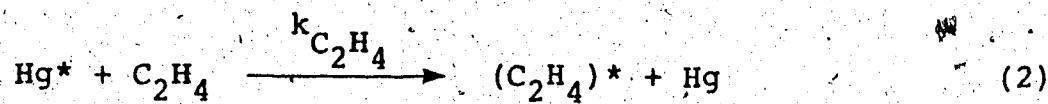

where  $\sigma^2$  is the collision cross-section, M the molecular weight, and the other terms have their usual significance.

Dividing equation I by II, we have

$$\frac{k_{H_2}}{k_{C_2H_4}} = \frac{\sigma_{H_2}^2}{\sigma_{C_2H_4}^2} \left[ \frac{M_{C_2H_4}}{M_{H_2}} \left( \frac{M_{Hg} + M_{H_2}}{M_{Hg} + M_{C_2H_4}} \right) \right]^{1/2} \quad III$$

Consider the following reactions:

The rate expressions for reactions (1) and (2) are:

$$\text{Rate}_{\text{Hg}+\text{H}_2} = k_{\text{H}_2} [\text{Hg}^*] [\text{H}_2]. \quad \text{IV}$$

$$\text{Rate}_{\text{Hg}+\text{C}_2\text{H}_4} = k_{\text{C}_2\text{H}_4} [\text{Hg}^*] [\text{C}_2\text{H}_4] \quad \text{V}$$

Dividing IV by V, we have

$$\frac{\text{Rate}_{\text{Hg}+\text{H}_2}}{\text{Rate}_{\text{Hg}+\text{C}_2\text{H}_4}} = \frac{k_{\text{H}_2} [\text{H}_2]}{k_{\text{C}_2\text{H}_4} [\text{C}_2\text{H}_4]} \quad \text{VI}$$

Hence,

$$\frac{k_{\text{H}_2} [\text{H}_2]}{k_{\text{C}_2\text{H}_4} [\text{C}_2\text{H}_4]} = \frac{\sigma_{\text{H}_2}^2}{\sigma_{\text{C}_2\text{H}_4}^2} \left[ \frac{M_{\text{C}_2\text{H}_4} \left( M_{\text{Hg}} + M_{\text{H}_2} \right)}{M_{\text{H}_2} \left( M_{\text{Hg}} + M_{\text{C}_2\text{H}_4} \right)} \right]^{1/2} \cdot \frac{[\text{H}_2]}{[\text{C}_2\text{H}_4]} \quad \text{VII}$$

In the present study  $[\text{H}_2] = 580 \text{ Torr}$ ,  $[\text{C}_2\text{H}_4] = 30 \text{ Torr}$ ; and since  $\sigma_{\text{H}_2}^2 = 10 \text{ } \text{\AA}^2, 116$ ,  $\sigma_{\text{C}_2\text{H}_4}^2 = 26 \text{ } \text{\AA}^2, 117$ ,  $M_{\text{H}_2} = 2$  and  $M_{\text{C}_2\text{H}_4} = 28$ , equation VII becomes

$$\frac{10}{26} \left[ \frac{28}{2} \left( \frac{202}{228} \right) \right]^{1/2} \times \frac{580}{30} = 26$$

Therefore the percentage quenching by  $\text{H}_2$  is

$$\begin{aligned}
 & k_{H_2} [H_2] [Hg^*] \\
 & \frac{k_{H_2} [H] [Hg^*] + k_{C_2H_4} [C_2H_4] [Hg^*]}{k_{H_2} [H_2] + k_{C_2H_4} [C_2H_4]} \times 100 \\
 & = \left( \frac{k_{H_2} [H_2]}{k_{H_2} [H_2] + k_{C_2H_4} [C_2H_4]} \right) \times 100 = \frac{1}{1.038} \times 100 = 96.3\%
 \end{aligned}$$

For all the systems examined in the present study, the maximum total pressures of sulfide or sulfide + ethylene were 30 Torr and the hydrogen pressure was always 580 Torr.

For  $CH_3SCH_3$ ,  $\sigma^2 = 49.3 \text{ \AA}^2$  <sup>87</sup> and the  $\sigma^2$  values for  $C_2H_5SC_2H_5$ ,  $CH_3SSCH_3$  and  $C_2H_5SSC_2H_5$  are probably not too different. Hence it is concluded that  $\geq 95\%$  of the excited mercury atoms are quenched by  $H_2$ .

## APPENDIX C

### Kinetic Treatment of the H + C<sub>2</sub>H<sub>4</sub> + C<sub>2</sub>H<sub>5</sub>SSC<sub>2</sub>H<sub>5</sub> System

The mercury photosensitized decomposition of 580 Torr hydrogen in the presence of 5 Torr C<sub>2</sub>H<sub>5</sub>SSC<sub>2</sub>H<sub>5</sub> yields C<sub>2</sub>H<sub>5</sub>SH as the only retrievable reaction product. In the presence of increasing amounts of ethylene at any given temperature, it has been shown that  $\phi(C_2H_5SH)$  decreases with increasing pressure of C<sub>2</sub>H<sub>4</sub>, owing to the competitive scavenging of H atoms by C<sub>2</sub>H<sub>4</sub>.

The following kinetic scheme was used to analyze the data:

In the unscavenged system, C<sub>2</sub>H<sub>5</sub>SH is assumed to be formed exclusively via steps (1), (2a) and (3), hence the following steady state equations apply:

$$\phi^\circ(H) = \phi^\circ(C_2H_5S) = 2\phi^\circ(2a) + 2\phi^\circ(2b) + \phi^\circ(3) = 2.0 \quad I$$

$$\phi^\circ(1) + \phi^\circ(2a) + \phi^\circ(3) = \phi^\circ(C_2H_5SH)_{\text{total}} \quad II$$

The rate expressions in the absence and presence of  $C_2H_4$  are:

$$R_1^\circ = k_1 [H]^\circ [C_2H_5SSC_2H_5] \quad III$$

$$R_{2a}^\circ = 2k_{2a} [C_2H_5S]^2 \quad IV$$

$$R_3^\circ = k_3 [C_2H_5S]^\circ [C_2H_5SSC_2H_5] \quad V$$

$$R_1 = k_1 [H] [C_2H_5SSC_2H_5] \quad VI$$

$$R_{2a} = 2k_{2a} [C_2H_5S]^2 \quad VII$$

$$R_3 = k_3 [C_2H_5S] [C_2H_5SSC_2H_5] \quad VIII$$

$$2I_a = k_1 [H]^\circ [C_2H_5SSC_2H_5] \quad IX$$

$$2I_a = k_1 [H] [C_2H_5SSC_2H_5] + k_4 [H] [C_2H_4] \quad X$$

where  $R^\circ$  and  $R$  are the rates in the absence and presence of  $C_2H_4$  respectively. Dividing  $R^\circ$  by the corresponding  $R$  and assuming that  $[H] = [C_2H_5S]$  and  $[H]^\circ = [C_2H_5S]^\circ$ , we obtain the following expressions:

$$\frac{R_1^\circ}{R_1} = \frac{[H]^\circ}{[H]} \quad XI$$

$$\frac{R_{2a}^\circ}{R_{2a}} = \frac{[H]^\circ 2}{[H]^2} \quad XII$$

$$\frac{R_3^o}{R_3} = \frac{[H]^o}{[H]}$$

XIII

Substituting for the values of  $[H]^o$  and  $[H]$  from Equations IX and X,

$$\frac{\phi^o(1)}{\phi(1)} = \frac{1 + \frac{k_4 [C_2H_4]}{k_1 [C_2H_5SSC_2H_5]}}{1 + \frac{k_4 [C_2H_4]}{k_1 [C_2H_5SSC_2H_5]}} \quad XIV$$

$$\frac{\phi^o(2a)}{\phi(2a)} = \left\{ 1 + \frac{k_4 [C_2H_4]}{k_1 [C_2H_5SSC_2H_5]} \right\}^2 \quad XV$$

$$\text{and } \frac{\phi^o(3)}{\phi(3)} = 1 + \frac{k_4 [C_2H_4]}{k_1 [C_2H_5SSC_2H_5]} \quad XVI$$

where  $\phi^o$  and  $\phi$  are the quantum yields in the absence and presence of  $C_2H_4$ . Assuming that Equation II also applies in the presence of  $C_2H_4$ , i.e.,

$$\phi(1) + \phi(2a) + \phi(3a) = \phi(C_2H_5SH)_{\text{total}} \quad XVII$$

and substituting for the values of  $\phi(1)$ ,  $\phi(2a)$  and  $\phi(3)$ , derived from Equations XIV, XV, and XVI respectively, in Equation XVII, we have

$$\frac{\phi^o(1)}{f} + \frac{\phi^o(2a)}{f^2} + \frac{\phi^o(3)}{f} = \phi(C_2H_5SH)_{\text{total}} \quad XVIII$$

where  $f = 1 + \frac{k_4 [C_2H_4]}{k_1 [C_2H_5SSC_2H_5]}$ , i.e.,  $f$  is the suppressing effect of added  $C_2H_4$  on the quantum yields.

By using Equation XVIII,  $f$  can be determined by iteration, and therefore, the values of  $\phi(1)$ ,  $\phi(2a)$  and  $\phi(3)$ , listed in Table XVII, can be calculated.
