To my family

**ABSTRACT**

The first Chapter of this thesis describes the synthesis of (±)-brevioxime. This fungal metabolite inhibits juvenile hormone biosynthesis and therefore constitutes a potential lead compound for development of novel insecticides. The most conspicuous feature of brevioxime is its hitherto unknown heterobicyclic core structure. Herein are described exploratory studies that led to the construction of this unique system by an acid-catalyzed double condensation of a β-ketoamide bearing a masked aldehyde. The methodology was applied first to the preparation of two model compounds and later to (±)-brevioxime. The route should be amenable to the preparation of analogs. The results of this work have been published (*Chem. Commun.* **1999**, 2251; *J. Org. Chem.* **2000**, *65*, 4923).

The second part of this thesis deals with synthetic studies on puraquinonic acid, a fungal metabolite that induces differentiation in leukemic HL-60 cells. Puraquinonic acid contains an asymmetric quaternary center, and the features of the molecule that are responsible for this asymmetry are far removed from it. Two routes for the synthesis of (±)-puraquinonic acid were developed, and approaches to the synthesis of the optically pure natural product were also explored. The syntheses of (±)-puraquinonic acid have been published (*J. Org. Chem.* **2001**, *66*, 954; *Tetrahedron Lett.* **2001**, *42*, 2253).

The third part of this thesis describes studies towards peptide segment coupling by prior ligation and proximity-induced intramolecular acyl transfer. Native chemical ligation is one of the emerging techniques for the synthesis of large proteins, both natural and unnatural, but the current approaches impose a severe restriction in that the *N*-terminus of one of he segments to be ligated has to be cysteine or glycine. The present studies aim at the development of a general method that will allow peptides to be ligated regardless of the identity of the amino acid at the *N*-terminus. Thus, specially derivatized amino acids that contain a cleavable template have been synthesized and were coupled to the *N*-terminus of short test segments. The template was then elaborated into a system that will, eventually, allow for the capture of another peptide segment via its *C*-terminus.

**ACKNOWLEDGMENTS**

I would like to express my gratitude to Dr. D. L. J. Clive for his constant support and encouragement during the course of my Ph.D. program, and for his assistance during the preparation of this thesis.

My thanks to all group members, past and present, for their friendship and useful discussions and for making my environment inspiring and enjoyable.

My thanks are also extended to the support staff (IR, MS, NMR, elemental analysis labs, glass blowing, electronic, machine and chemical shops) for their valuable help and advice.

Finally, I would like to thank my family for their support encouragement, patience and understanding.

## Table of Contents

## List of abbreviations

| | |
|---|---|
| Ac | acetyl |

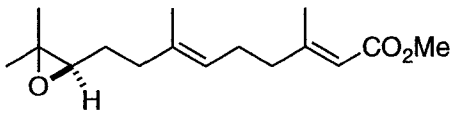
# SYNTHESIS OF (±)-BREVIOXIME AND (±)-PURAQUINONIC ACID AND STUDIES ON PEPTIDE LIGATION AND ACYL TRANSFER

# CHAPTER 1

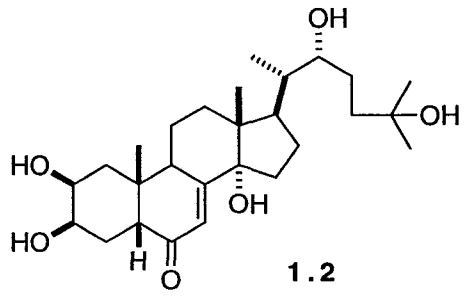
## SYNTHESIS OF (±)-BREVIOXIME

### Introduction

Insect growth and development is controlled by hormones, and substances that inhibit the formation of these hormones represent, in principle, an attractive method for pest control.[1] Well-known examples of these hormones are juvenile hormones, such as juvenile hormone III (**1.1**) (Scheme 1), and ecdysone (**1.2**).[1]



**1.1**



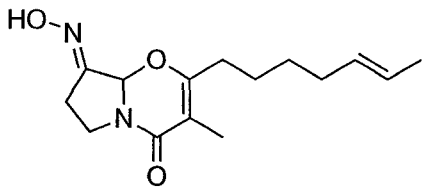
**1.2**

**Scheme 1**

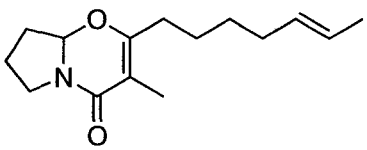
The first part of this Thesis deals with the synthesis of brevioxime (**2.1**), which inhibits the formation of one of these important insect hormones – juvenile hormone III.

Brevioxime was isolated[2,3] from a strain of the fungus *Penicillium brevicompactum*, and its structure was reported a few years ago.[2] The substance was found to be a potent inhibitor of juvenile hormone III biosynthesis[2,3] and it appears to block those enzymatic steps of the isoprenoid

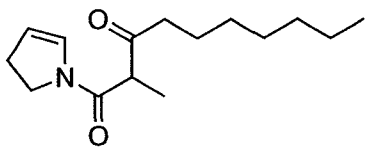
pathway that are specific for insects.[3] These properties make it a potential lead compound for the development of



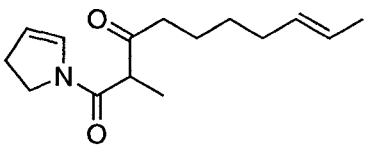
**2.1**



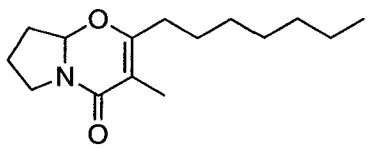
**2.2**



**2.3**



**2.4**



**2.5**

**Scheme 2**

insecticides. The related compounds **2.2**,[4] **2.3**,[5] and **2.4**[4] have also been isolated from the same fungus, and their biological properties examined. Compounds **2.3** and **2.4** both inhibit formation of juvenile hormone, but the mode of action of **2.2**, which is also an insecticide, does not appear to have been established.

The structure of brevioxime is an unusual one and, although a number of benzo-fused substances containing a similar ring system are known, those lacking a fused benzene ring are rare.[6,7] The only other unsaturated examples we know of are compounds made in this laboratory and described below,

as well as model compounds prepared[4,5] by the discoverers of brevioxime.

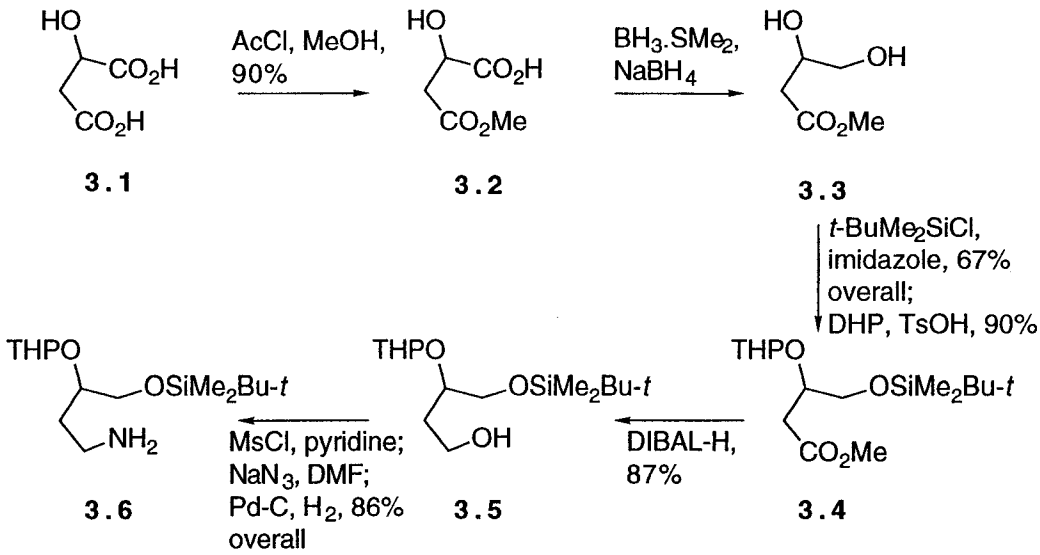
**Other syntheses of brevioxime**

Apart from our own synthesis,[8] which is discussed in the next section, three other syntheses of brevioxime have been reported, as well as the preparation of some simple model compounds.

**Kitahara's synthesis**

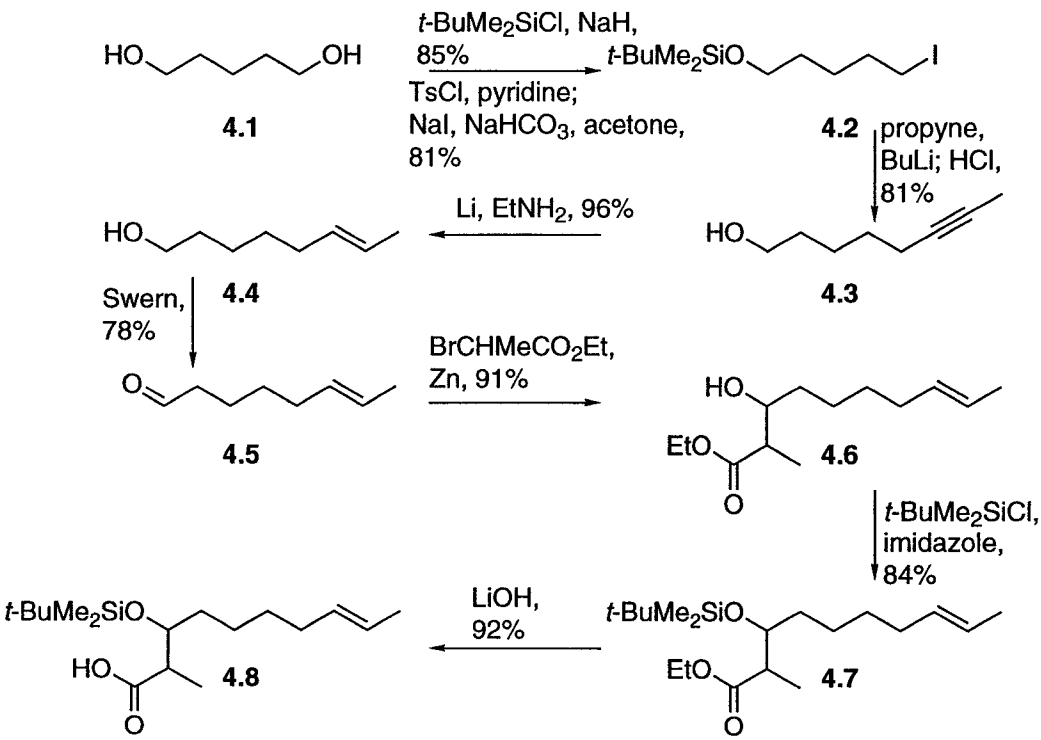
Nishimura and Kitahara reported[9] a synthesis that is very similar in conception to our route. Their work actually represents the first synthesis of brevioxime, as the receipt date for their manuscript is 1 May 1999, while that for our work is 10 August 1999. However, the Kitahara paper did not appear until the following year, and we were unaware of it even when we later submitted our own full paper. We do not know the reason for the apparent delay in publishing the Japanese work.

Nishimura and Kitahara assembled racemic brevioxime from two subunits **3.6** and **4.8**. The former was made (Scheme 3) from (±)-malic acid (**3.1**) by esterification and borane reduction of the remaining carboxyl (**3.1** → **3.2** → **3.3**). Selective silylation of the primary hydroxyl of **3.3** and protection of the remaining secondary hydroxyl as its THP ether gave **3.4**. This was reduced to a primary alcohol (**3.4** → **3.5**), and the hydroxyl was replaced by an amino group,



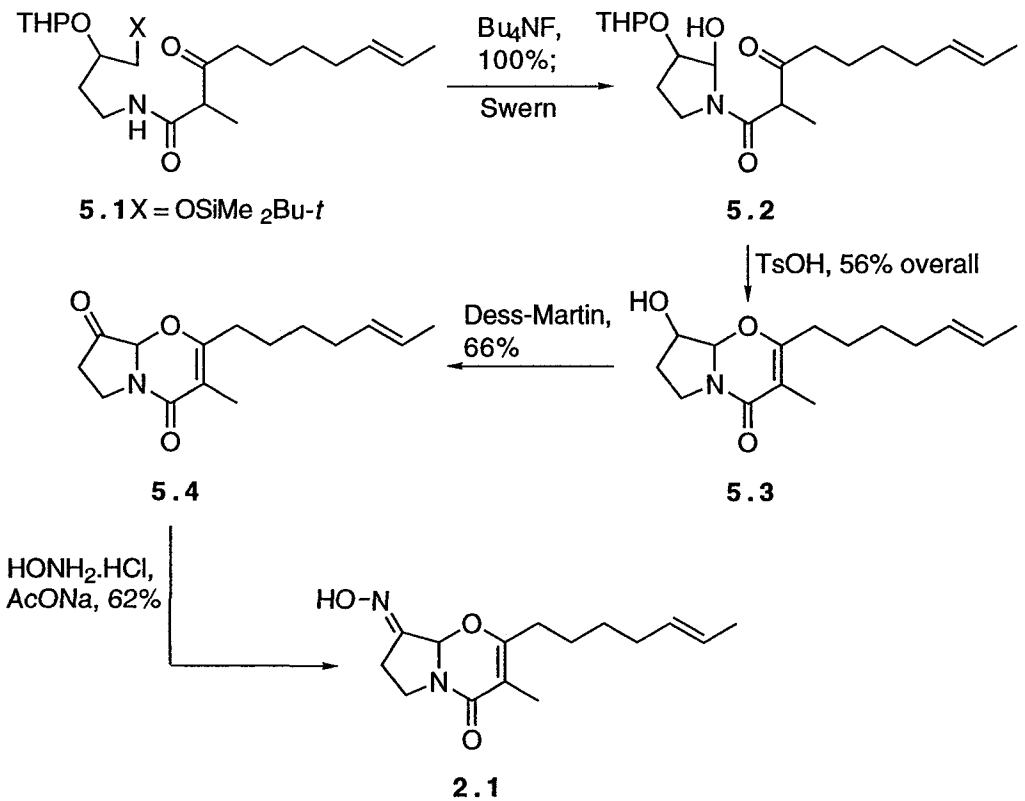
**Scheme 3**

using the classical sequence: mesylation, displacement with azide ion, and hydrogenation. All steps leading to the final amine **3.6** worked in acceptable yields.



**Scheme 4**

The other subunit was acid **4.8**, which was prepared as shown in Scheme 4. The pentanediol **4.1** was monosilylated and the remaining hydroxyl was replaced by iodine via tosylate displacement. The iodide, in turn was displaced, using the acetylide generated from propyne, and removal of the silyl protecting group then gave acetylenic alcohol **4.3**. Dissolving metal reduction converted the triple bond into an *E*-double bond (**4.3** → **4.4**), and the resulting alcohol **4.4** was oxidized to the corresponding aldehyde. A Reformatsky reaction then took the route as far as **4.6**. The hydroxyl was silylated, and the ester was hydrolyzed. The resulting acid **4.8** was converted into its acid chloride, using oxalyl chloride, and condensation with amine **3.6** gave amide **5.1**



**Scheme 5**

(Scheme 5).

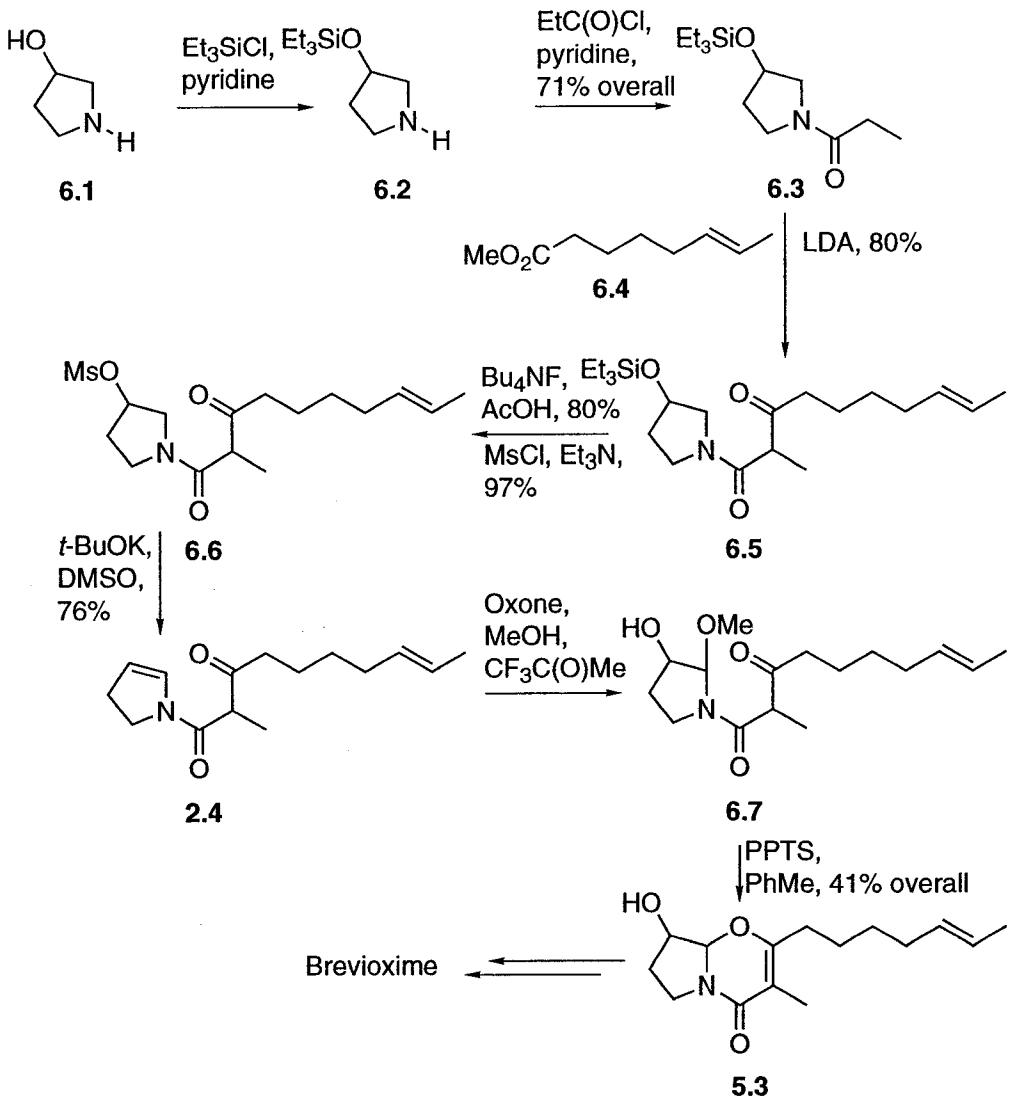
Selective deprotection and Swern oxidation afforded the hemiaminal **5.2**, which was in equilibrium with a trace amount of the corresponding ring-opened aldehyde. Treatment with TsOH effected cyclization and removal of the tetrahydropyranyl group, and alcohols **5.3** were obtained as a mixture of isomers (ca 1:1). Dess-Martin oxidation gave the expected ketone (**5.4**), and treatment with $HONH_2.HCl$ under standard conditions[10] produced a mixture (ca 1:1) of *Z*- and *E*-oximes. These isomerized during crystallization, and only the desired *E*-oxime was obtained.

Since the diastereoisomers of **5.3** were easily separable, use of optically pure malic acid should afford optically pure brevioxime (if there is no epimerization in the conversion of **5.1** into **5.2**), but this sequence does not appear to have been reported.

**Clark's synthesis**

Clark, working at DuPont, devised a synthesis of (±)-brevioxime, which was also adaptable to the synthesis of the natural (-)-antipode, although the compound was not obtained optically pure.[11]

3-Hydroxypyrrolidine was silylated and then acylated with propionyl chloride (Scheme 6, **6.1** → **6.2** → **6.3**). Amide **6.3** was then deprotonated and condensed with 0.5 equivalents of ester **6.4**, so as to form the β-keto amide **6.5**. Desilylation, mesylation, and treatment with *t*-BuOK served to



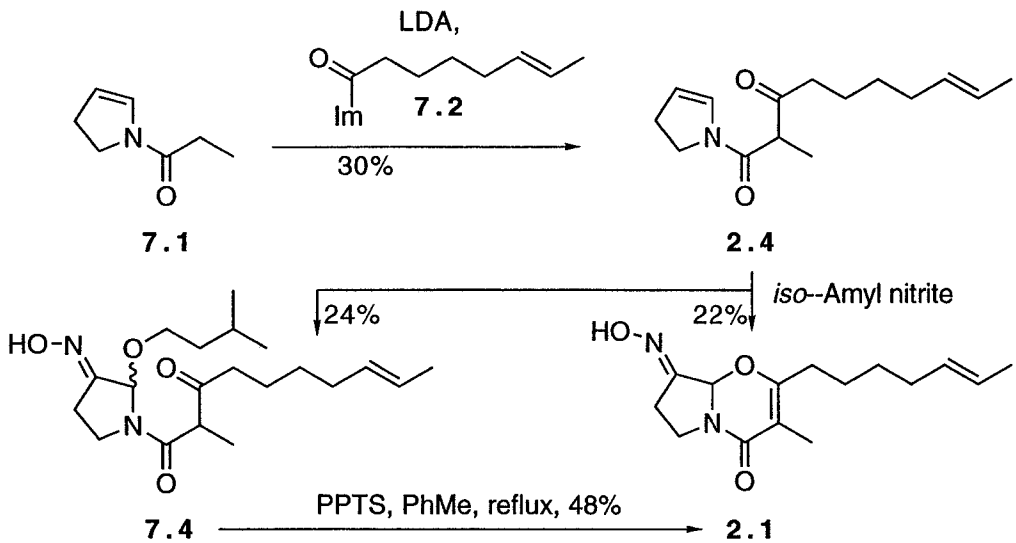
**Scheme 6**

generate the required double bond (**6.5** → **6.6** → **2.4**), each of the steps proceeding in good yield. Oxidation with Oxone in the presence of MeOH gave the hemiaminal methyl ethers **6.7**, and these were cyclized by heating with pyridinium *p*-toluenesulfonate (**6.7** → **5.3**). The resulting alcohols, which could be readily separated, were oxidized using the Dess-Martin reagent, and the resulting ketone was converted into its *E*-oxime [i.e. (±)-brevioxime].

In an effort to obtain optically active brevioxime, **2.4** was treated with (*S*,*S*)-(+)-*N*,*N*′-bis(3,3-di-*tert*-butyl-salicylidene)-1,2-cyclohexanediaminomanganese(III) chloride to afford material corresponding to **6.7**. This was then processed as for the racemic series to give optically active brevioxime, but the compound was of low ee (probably 19%).

**Parsons' synthesis**

Quite recently, Karadogan and Parsons have described a short route (Scheme 7) to (±)-brevioxime.[12] It is based on the approaches of the prior syntheses, and its main innovative feature is to combine the final cyclization with formation of an oxime function.

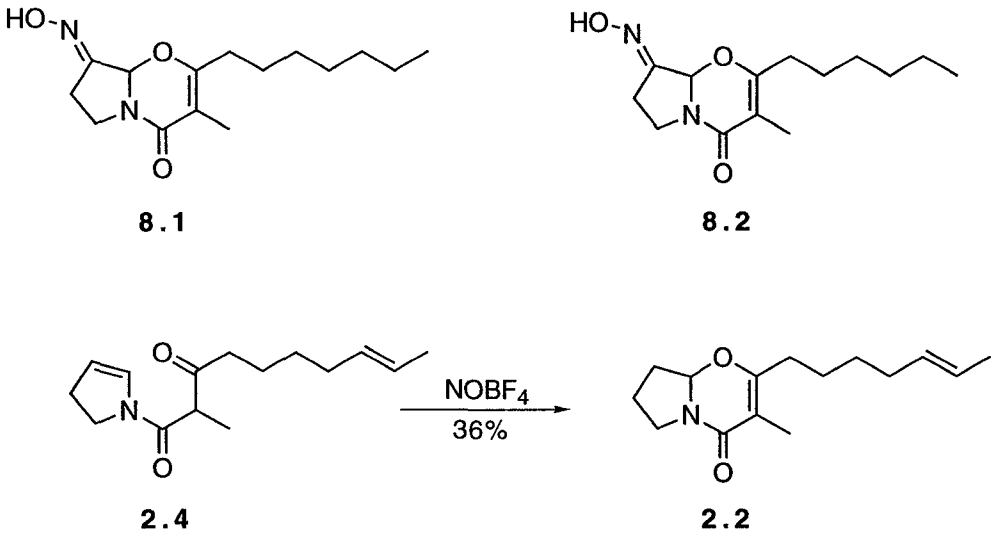


**Scheme 7**

Enamide **7.1**, was prepared by the literature method (which will be described in the section dealing with our own synthesis), and the derived enolate was condensed with

imidazolide **7.2**. This experiment afforded the coupled product **2.4** in 30% yield. Simultaneous cyclization and oximation occurred on treating **2.4** with *iso*-amyl nitrite. Two products were formed: brevioxime and the α-alkoxy oxime **7.4**. The latter was converted into brevioxime on heating in the presence of pyridinium *p*-toluenesulfonate.

The simple brevioxime analogs **8.1** and **8.2** were made similarly, and an attempt to use $NOBF_4$ as the nitrosating agent served to convert **2.4** into the natural product **2.2**, presumably by the action of adventitious $HBF_4$.



**8.1** **8.2**

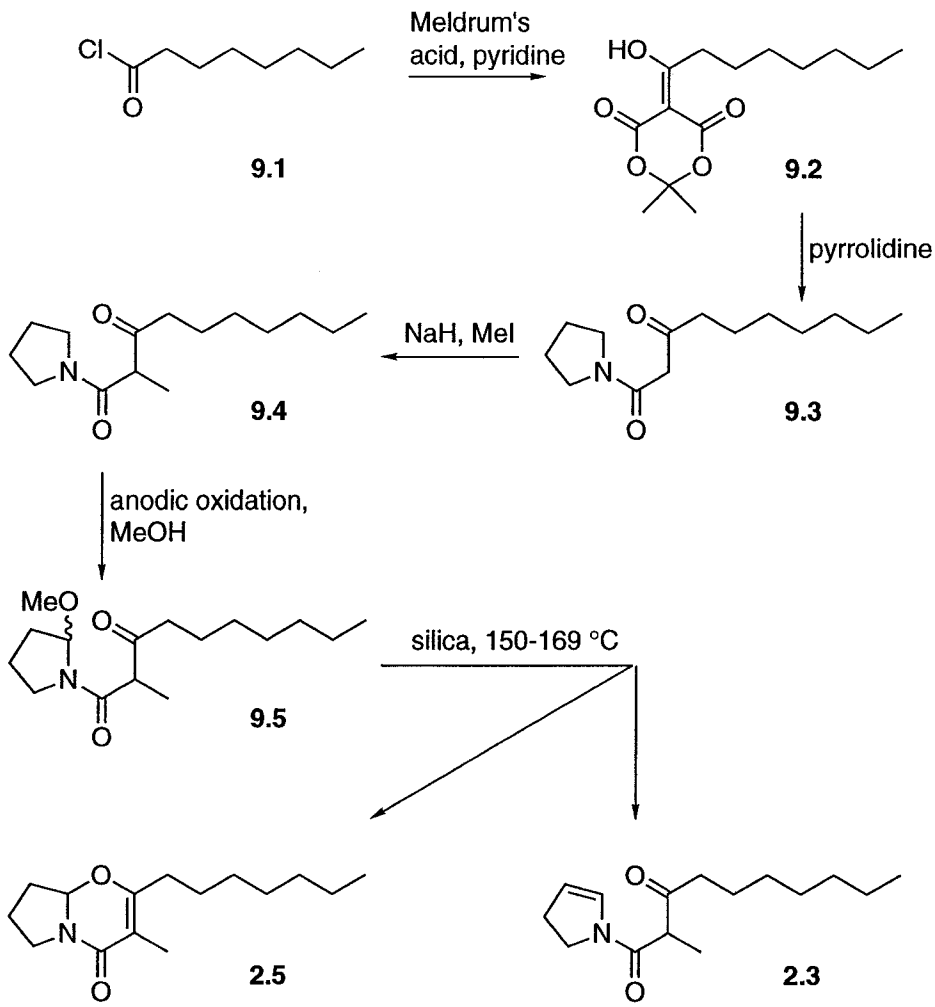
**2.4** **2.2**

**Scheme 8**

**Synthesis of related compounds**

The group that isolated brevioxime also made the related compounds **2.3**, **2.5**, **2.2** and **2.4** – all except **2.5** being natural products isolated from *Penicillium brevicompactum*.[4,5]

Acylation of Meldrum's acid with octanoyl chloride gave the enolized triketone **9.2**, which, without purification, was



**Scheme 9**

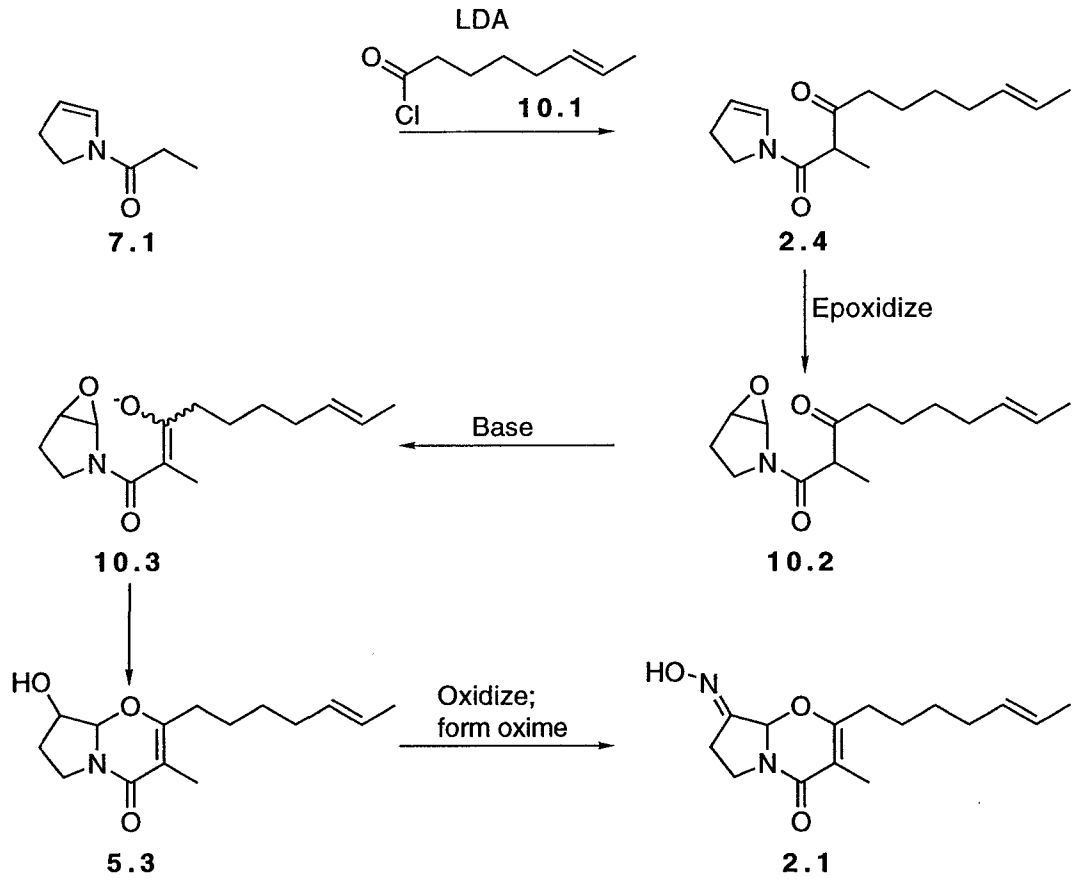
heated with pyrrolidine, so as to form the β-keto amide **9.3**. Methylation in the usual way (NaH, MeI, DMF) and anodic oxidation generated the hemiaminal methyl ethers **9.5**. These were adsorbed on silica gel and the solid was heated at 150-160 °C. Under these conditions a separable 1:1 mixture of **2.5** and **2.3** was obtained. Compound **2.3** shows anti-juvenile hormone activity, while **9.3** and **9.4** showed strong knockdown toxicity to *Oncopeltus fasciatus*. The corresponding compounds with an olefinic side chain (**2.2** and **2.4**) were

made by the same route but using 6-octenoyl chloride.[4]

## DISCUSSION OF RESEARCH RESULTS

### Synthesis of (±)-brevioxime

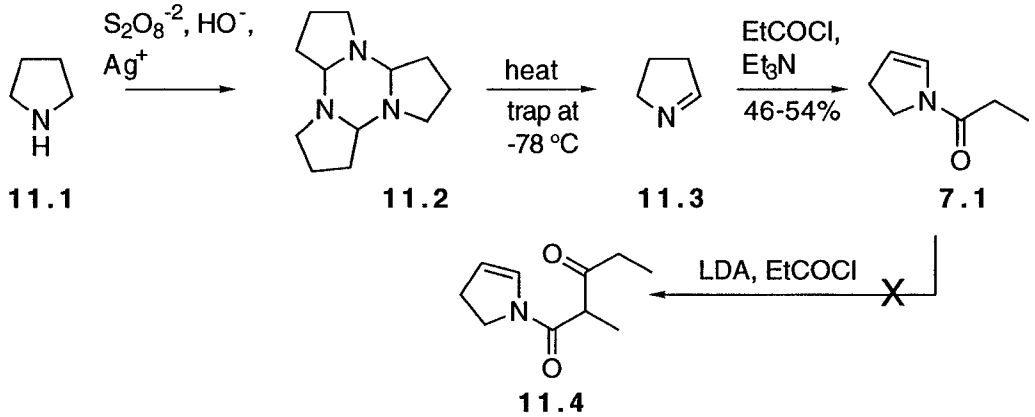
Our first approach is summarized in Scheme 10. Acylation of the enamide **7.1** with acid chloride **10.1** was expected to afford the required carbon skeleton of brevioxime (**7.1** → **2.4**).



**Scheme 10**

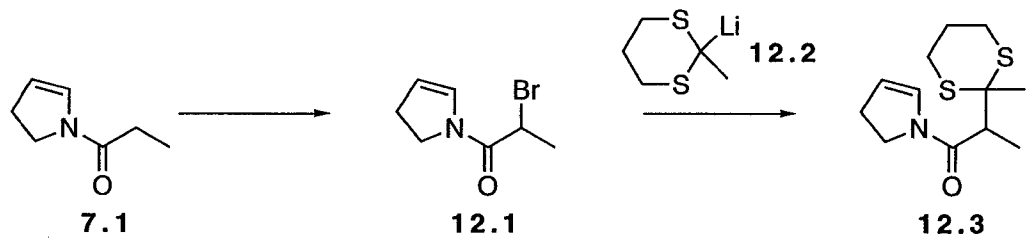
We decided to test this approach by first making the β-keto enamide **11.4** (Scheme 11). To this end, we prepared enamide **7.1**, starting from pyrrolidine (**11.1**). The latter compound was oxidized under conditions that afforded the

trimer **11.2**.[13] This was heated to afford **11.3**, and acylation with propionyl chloride[14] then gave **7.1** in 46-54% overall yield. We made one attempt to acylate the derived enolate (**7.1** → **11.4**). This was unsuccessful, and so we sought – perhaps prematurely – an alternative approach to compounds of type **11.4**.

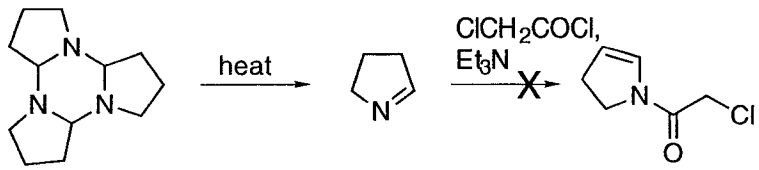


**Scheme 11**

We decided to make **12.1** and then displace the halogen with a lithiated dithiane (Scheme 12). Treatment of **7.1** with LDA and NBS gave some of the desired bromo enamide **12.1**, but the yield was too low (8%) to be useful. The related compound **13.1** is known,[14] but our attempt to prepare it (Scheme 13) was unsuccessful.



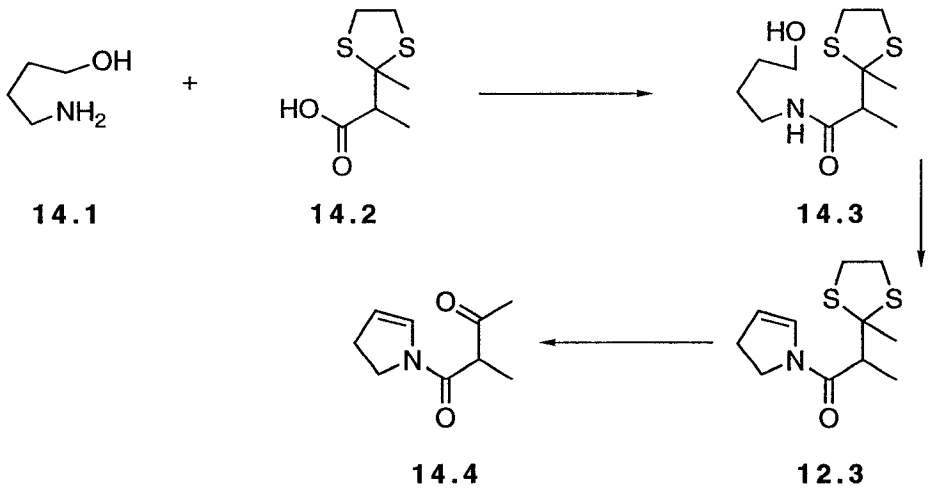
**Scheme 12**



**11.2** **11.3** **13.1**

**Scheme 13**

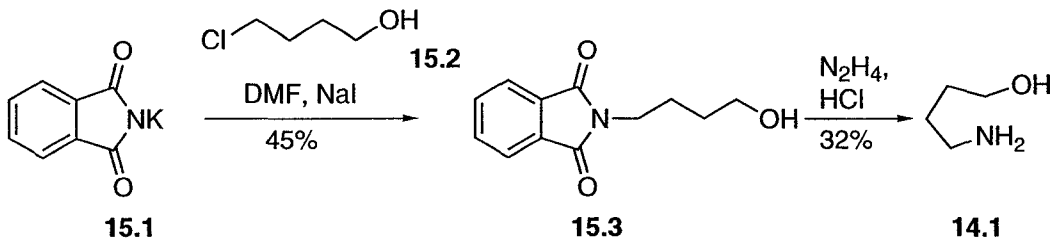
Although these preliminary experiments had not been pursued with determination, we decided to modify our approach to brevioxime in such a way that a *preformed* 1-pyrroline unit was not used, but was generated *in situ* after the complete carbon skeleton had been assembled. The new plan is illustrated in Scheme 14, for preparation of the simple intermediate **14.4**.



**14.1** **14.2** **14.3** **14.4** **12.3**

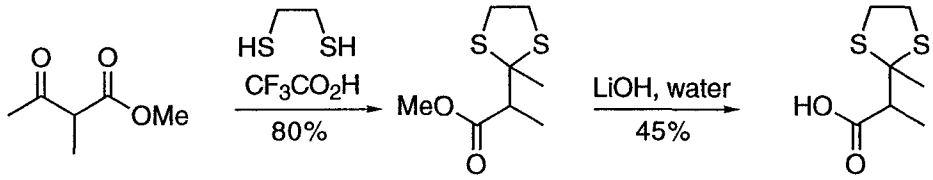
**Scheme 14**

Amine **14.1**[15] was prepared by a standard Gabriel synthesis (Scheme 15) from 4-chlorobutanol (**15.2**). The yields were poor in each of the two steps, and we made no attempt to improve them.



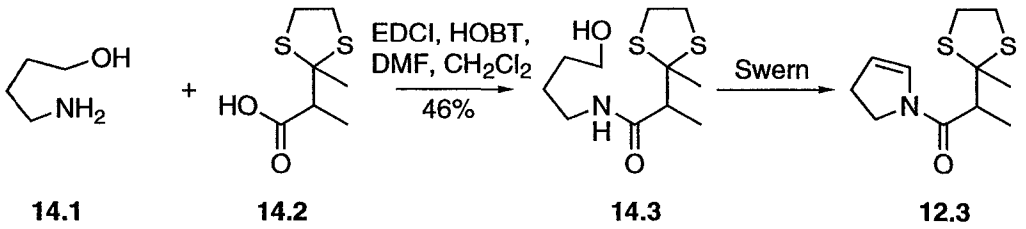
**Scheme 15**

The other component (**14.2**) was also made in two steps (Scheme 16). Thioketalization of the β-keto ester **16.1**[16] worked smoothly when $CF_3CO_2H$ was used as the catalyst[17] but an attempt to use $Me_3SiCl$[18] did not work. Hydrolysis with LiOH then gave the required acid (**14.2**).



**Scheme 16**

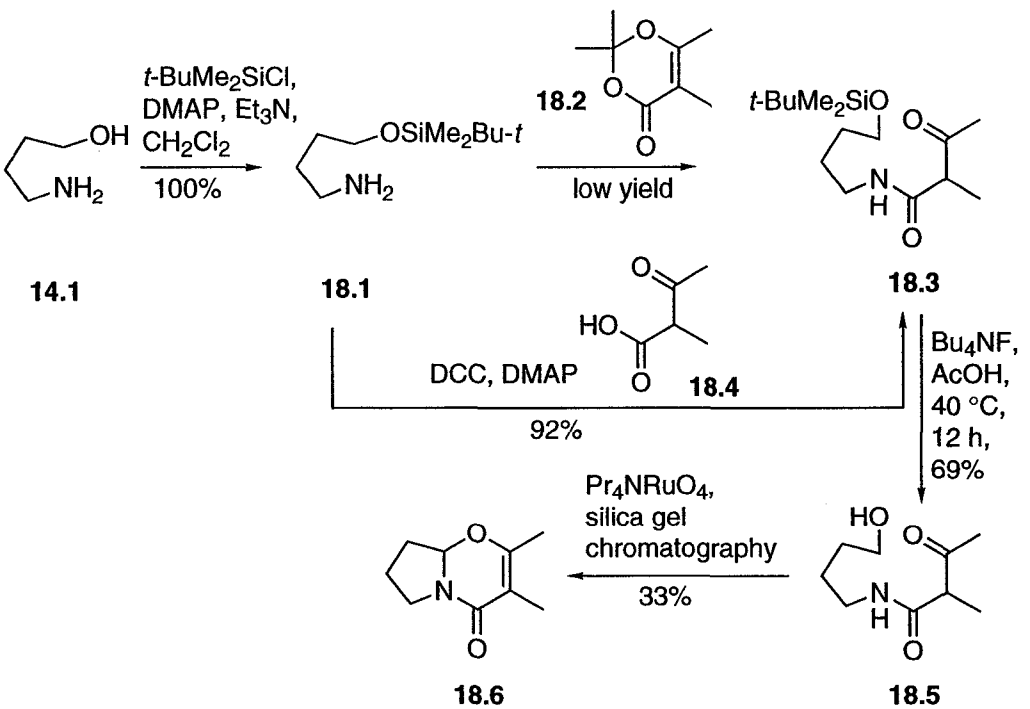
Amine **14.1** and acid **14.2** were coupled using the standard EDCI method (Scheme 17); a single attempt at the coupling, using DCC and DMAP was unsuccessful. Swern oxidation of



**Scheme 17**

alcohol **14.3** gave some of the desired *N*-acyl pyrroline **12.3**, but the yield was very low. Rather than attempt to improve it, we decided to deprotect the latent ketone group before oxidizing the primary alcohol. Unfortunately, the standard deprotection conditions we tried ($HgCl_2$, $CaCO_3$, MeCN, water[19] or $HgCl_2$, MeCN, water) gave none of the desired product, although the starting dithioketal was destroyed in both cases.

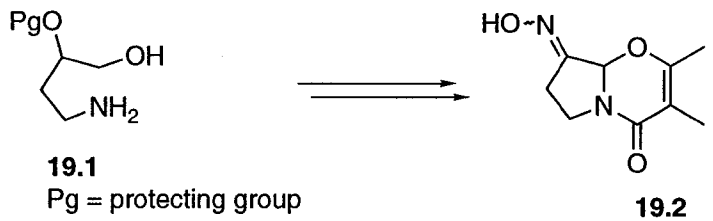
These observations suggested that the β-dicarbonyl unit should be installed in an unprotected form, and we decided, in view of the low yield we had obtained in an earlier coupling (see **14.1** + **14.2** → **14.3**), to use an amino alcohol in which the hydroxyl was protected. Thus, amino alcohol **14.1** was silylated (Scheme 18), and the resulting amine



**Scheme 18**

(**18.1**[20]) was condensed efficiently with β-keto acid **18.4**,[21] using DCC. The keto acid is sensitive, and so we also tried to effect coupling with the dioxinone **18.2**.[22] Some of the desired coupled product was indeed formed, but the yield was low, and we had to accept the slight inconvenience of working with keto acid **18.4**.

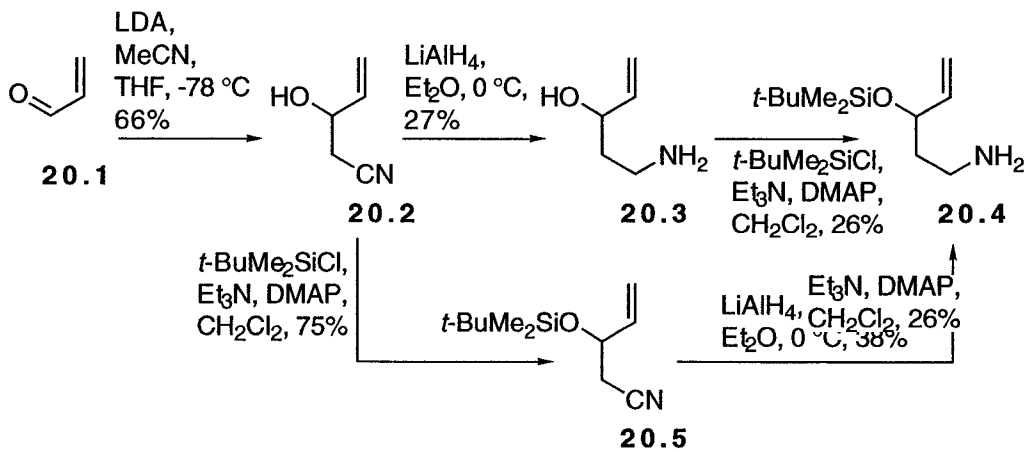
Desilylation of **18.3** and TPAP oxidation allowed us to isolate the desired model **18.6** in 33% yield. Appropriate $^1H$ NMR measurements showed that the intermediate aldehyde cyclizes while in contact with silica gel.[23] $CF_3CO_2H$ and TsOH can also induce cyclization, but the yield was no higher than with silica gel. The formation of **18.6** seemed to validate the approach based on amide closure onto an aldehyde group,



**19.1**
Pg = protecting group

**19.2**

**Scheme 19**

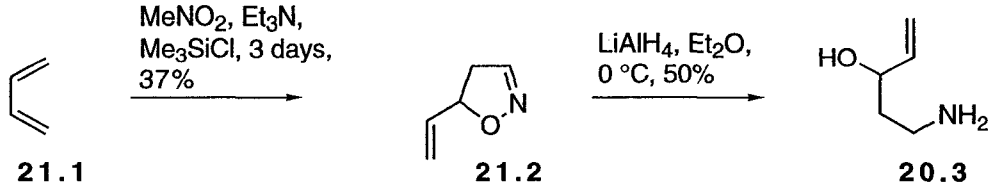


**20.1** **20.2** **20.3** **20.4** **20.5**

**Scheme 20**

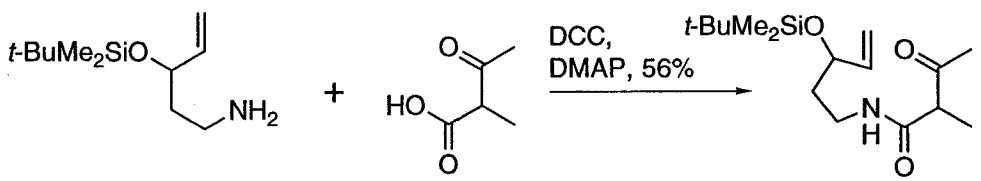
followed by another cyclization involving the β-ketone function, and we next sought to prepare the more advanced model **19.2**, by an analogous route, so as to gain experience in generating the oxime function. For this purpose, the required amino unit was of type **19.1**, and our initial approach to a precursor of this class is shown in Scheme 20.

Our plan was to make amino olefin **20.4**, and to then cleave the double bond after acylation of the amino group with β-keto acid **18.4**. The amino olefin was prepared as follows: Deprotonation of MeCN and condensation with acrolein gave the hydroxy nitrile **20.2**,[24] but $LiAlH_4$ reduction afforded the amine **20.3**[25] in only 27% yield. This was silylated, to produce the *O*-protected amine **20.4**.[26] Reversing the order of the last two steps improved the overall yield, but only to 29% (Scheme 20). We also looked briefly at a different approach (Scheme 21). Butadiene was converted (37%) into the isoxazoline **21.2** by the literature procedure,[27] and $LiAlH_4$ reduction then gave alcohol **20.3**.[27] The route summarized in Scheme 21 was not pursued, as a better route (see later) was developed at about the same time.



**Scheme 21**

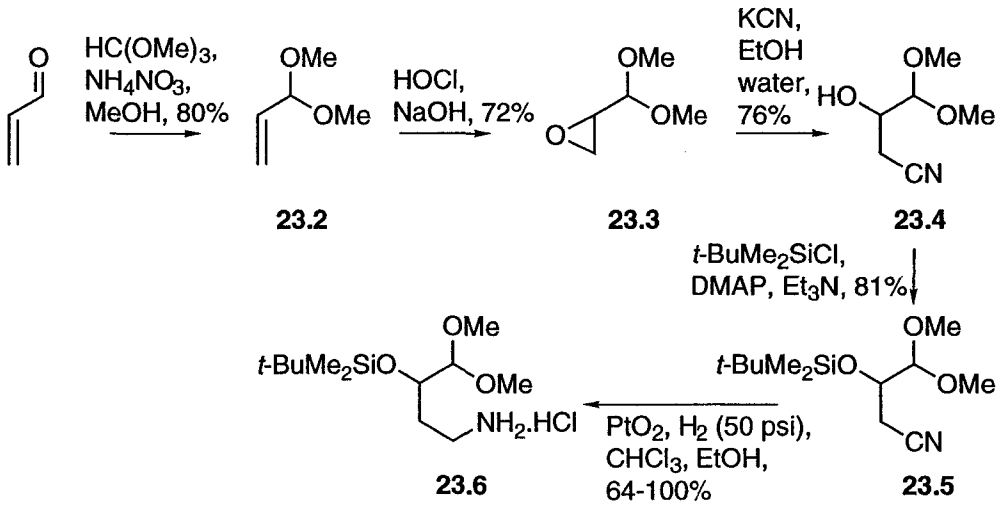
The reduction of our aliphatic nitriles by $LiAlH_4$ does not appear to be an easy process, and we eventually found a route that avoids this troublesome step. However, with some of the protected amine **20.4** in hand, we proceeded to couple the material with acid **18.4**, using DCC as the coupling reagent (Scheme 22). When we attempted to cleave the double bond in the product (**22.1**) with $O_3$ ($Ph_3P$ reduction) we were



**20.4** **18.4** **22.1**

**Scheme 22**

unable to isolate characterizable products. We did not try $OsO_4$-$NaIO_4$ but, instead, prepared compound **23.6** in which the aldehyde function was protected as a dimethyl acetal rather than as a double bond. In the event, this approach proved to



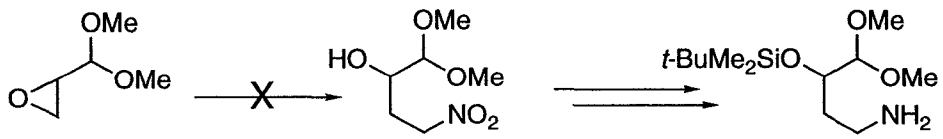
**23.2** **23.3** **23.4** **23.5** **23.6**

**Scheme 23**

be successful and was used in the synthesis of brevioxime.

Acrolein was converted into its dimethyl acetal[28] and this was epoxidized with NaOCl, following a standard general[29] procedure. Epoxide opening with KCN in aqueous EtOH[30] proceeded without incident, and the hydroxyl was protected by silylation under standard conditions (**23.4** → **23.5**). When we came to reduce the nitrile function we found the reaction very troublesome. $LiAlH_4$ did not give the required product, but we eventually found that catalytic hydrogenation over $PtO_2$ in the presence of several equivalents of $CHCl_3$,[31] which serves as a controlled source of HCl, gave the desired amine as its hydrochloride salt in yields varying from 64 to 100% yield. We did not attempt to identify the cause of the yield variation, but we did notice that the spent catalyst in the case of the quantitative reaction was inflammable. This method of reducing nitriles deserves to be better known.

Our problems with the reduction had also caused us to look at the possibility of using a nitro compound (Scheme 24), as it was known in this laboratory[32] that the reduction of aliphatic nitro groups with $NaBH_4$-$NiCl_2.6H_2O$[33] works very well. However, the single attempt we made to prepare **24.1**

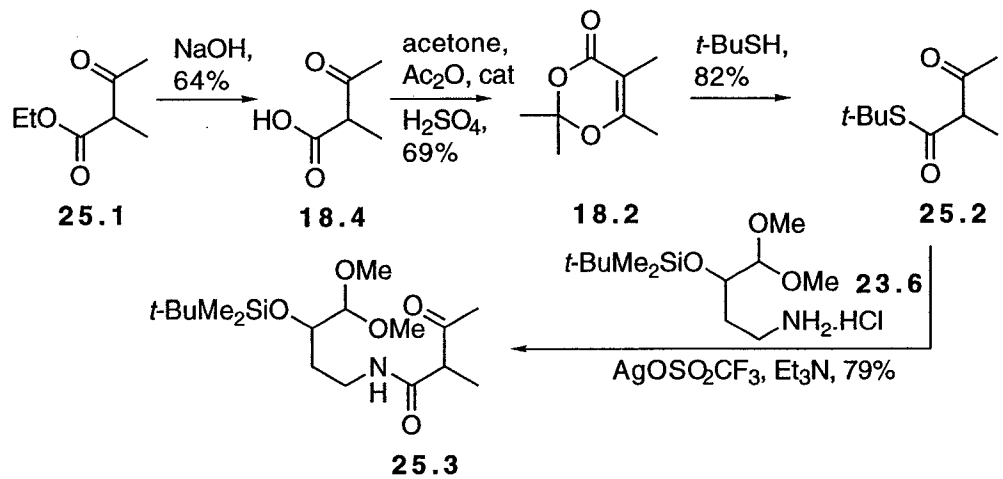


**23.3** **24.1** **24.2**

**Scheme 24**

($MeNO_2$, *t*-BuOK)[34] was unsuccessful, and we had by that time found the $PtO_2$-$H_2$-$CHCl_3$ method.

When amine **23.6** was coupled with keto acid **18.4**, using DCC, the required product was indeed formed but it was contaminated by significant amounts of *N,N'*-dicyclohexylurea, and purification was difficult. We turned, therefore, to the general method for the preparation of β-keto amides reported by Ley *et al.*[35] This involves $Ag^+$-mediated reaction of an amine with a β-keto thioester. The requisite material for the present case is thioester **25.2**. Hydrolysis of ester

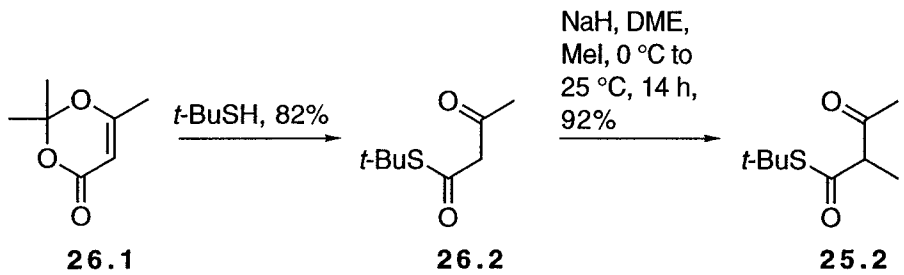


**Scheme 25**

**25.1**[21] afforded the sensitive acid **18.4**, and this was converted into the dioxinone **18.2**, which reacted with *t*-BuSH, giving the desired β-keto thioester **25.2**.[36] Coupling of the thioester with the amine component **23.6** was achieved in 79% yield by using $AgOSO_2CF_3$ (**25.2** → **25.3**).

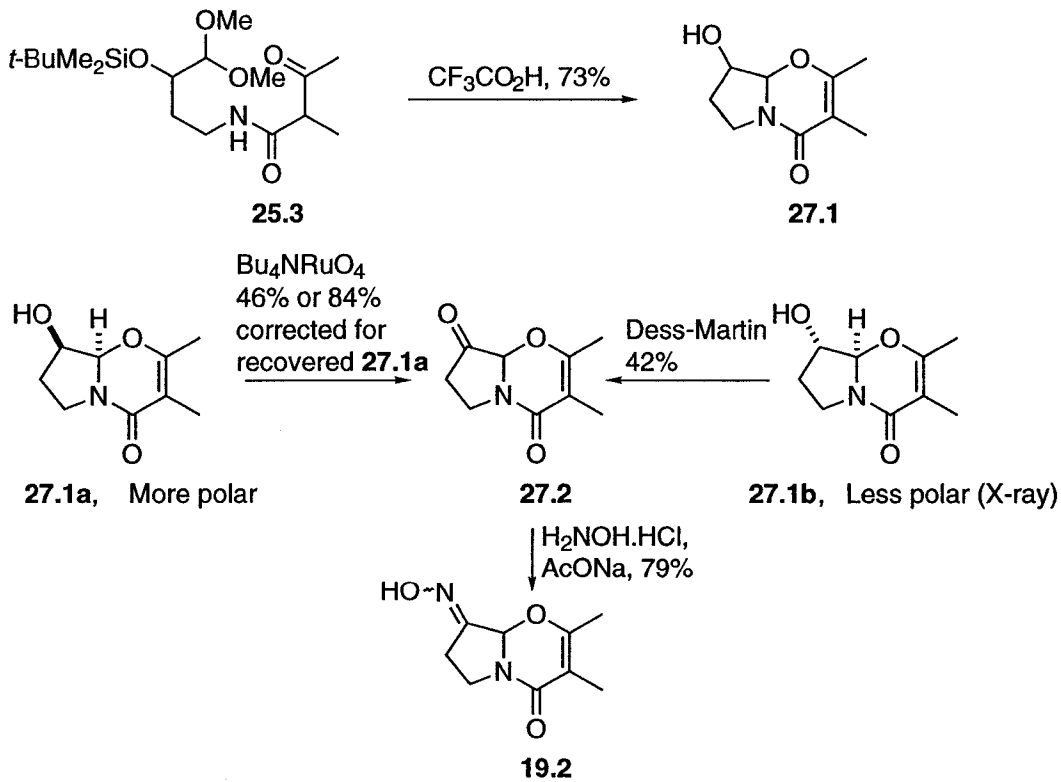
At this point a slight improvement in the preparation of thioester **25.2** was made. Acid **18.4** is unstable and handling

this compound was now avoided by using[36] commercial **26.1** and alkylating[37] the derived β-keto thioester **26.2**, as summarized in Scheme 26.



**Scheme 26**

With **25.3** in hand, a number of conditions were examined to effect conversion into the desired bicyclic system ($BF_3.OEt_2$; $Me_3SiCl$, NaI, MeCN; oxalic acid, silica gel;



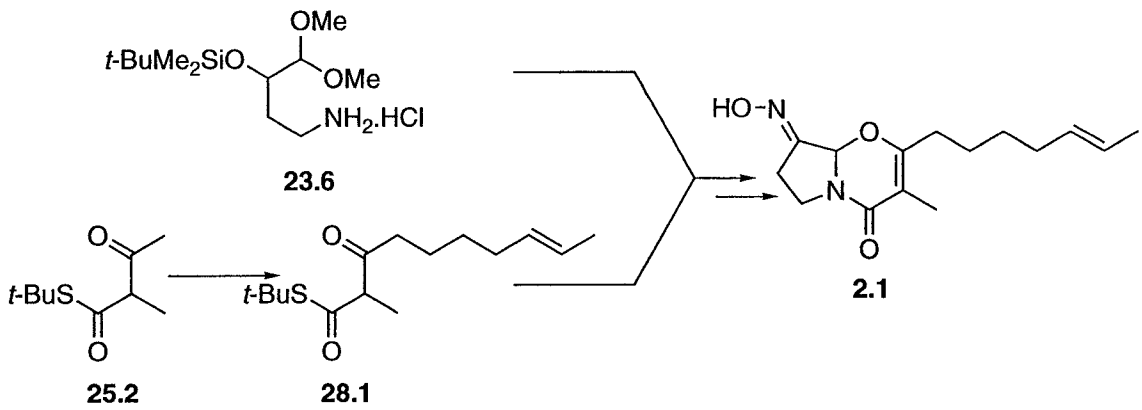
**Scheme 27**

$TsOH.H_2O$, acetone, reflux; $CF_3CO_2H$, $CHCl_3$), but only the use of $CF_3CO_2H$ in $CHCl_3$ was successful and afforded **27.1** as a mixture of two isomers, the more polar material being obtained in 36% yield and the less polar in 37% yield. X-ray crystallographic analysis of the latter established that the hydroxyl and adjacent angular hydrogen are *syn* (see Appendix for X-ray data).

We tried to oxidize the more polar compound with the Dess-Martin reagent, but the substance was inert; use of $Pr_4NRuO_4$-NMO,[38] however, gave ketone **27.2** in 46% yield, or 84% after correction for recovered starting material. The less polar isomer was destroyed by $Pr_4NRuO_4$, but gave **27.2** in 42% yield with the Dess-Martin reagent. We interpret the different behavior of the isomers towards the two reagents in the following way. The bulky Dess-Martin reagent can approach only the *exo* hydroxyl, as in the less polar isomer. If the ruthenium reagent acts as a hydride acceptor[39] then it would react only with that isomer having an *exo* hydrogen on the carbon bearing the hydroxyl, as in the more polar isomer.

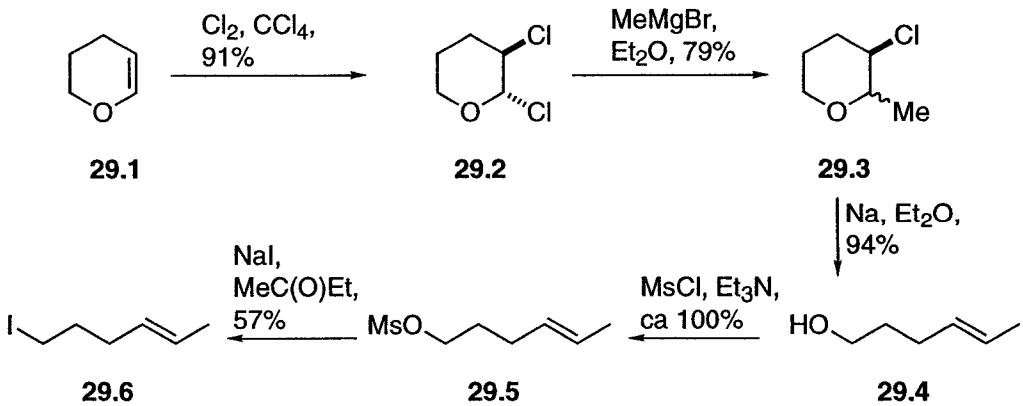
Treatment of ketone **27.2** with hydroxylamine under classical conditions[10] afforded in 73% yield the *E*-oxime together with a small amount (6% yield) of the *Z*-isomer.

With these encouraging results in hand, we embarked on the synthesis of brevioxime itself. For this purpose – by analogy with our model studies – we needed the two components **23.6** and **28.1** (Scheme 28), and our first task was to prepare the thioester **28.1**. Since ester **25.2** was available from our



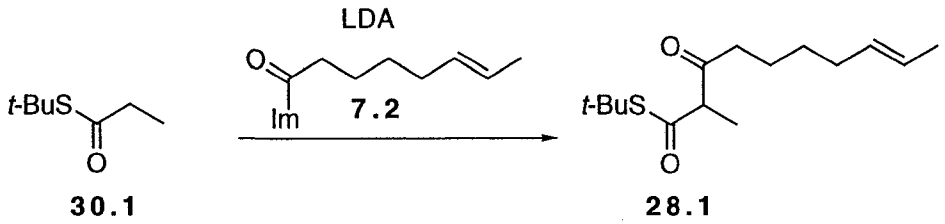
**Scheme 28**

model studies we naturally tried to alkylate it with (*E*)-6-iodo-2-hexene (**29.6**). This known iodide[40] was made by the classical route shown in Scheme 29,[41] the literature procedures for conversion of dihydropyran to alcohol **29.4** being easily repeatable. In the preparation of 3-chloro-tetrahydro-2-methylpyran by the literature procedure,[41b] use of a mechanical stirrer is essential because, if the mixture is not stirred vigorously, the reaction becomes violent after 2/3 of the Grignard reagent has been added. The initial chlorination of dihydropyran was done in $CCl_4$ instead of $Et_2O$.



**Scheme 29**

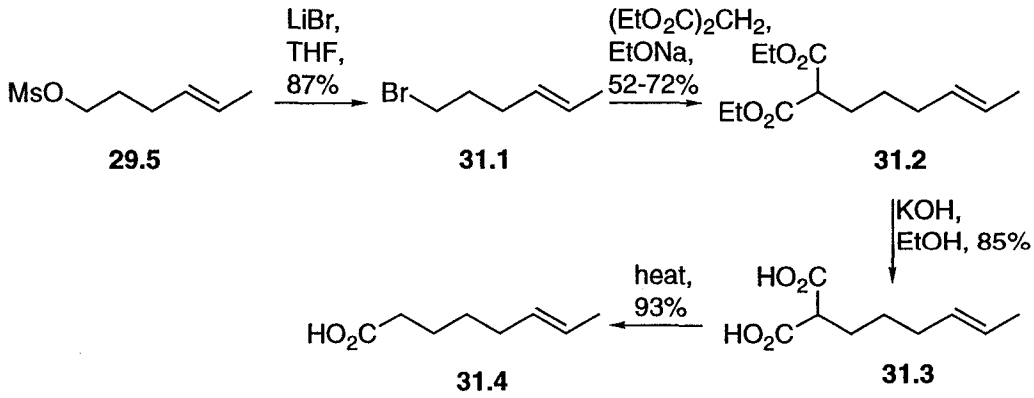
Alcohol **29.4** is reported[41b] to contain <5% of the *Z*-isomer, and so the material was subjected to spinning band distillation to afford the pure *E*-olefin (20% recovery). The alcohol was converted into its mesylate, and displacement with NaI gave the required iodide **29.6**. When the iodide was used to alkylate the dianion[42] derived from **25.2**, we were disappointed to find that the yield of the desired **28.1** was very poor (33%). Almost the same result was obtained in alkylation of **26.2**. The inefficiency of these procedures caused us to adopt the route shown in Scheme 30.[43]



**30.1** **28.1**

**Scheme 30**

The imidazolide **7.2** was prepared (Scheme 31) from mesylate **29.5**. Mesylate **29.5** was converted into bromide

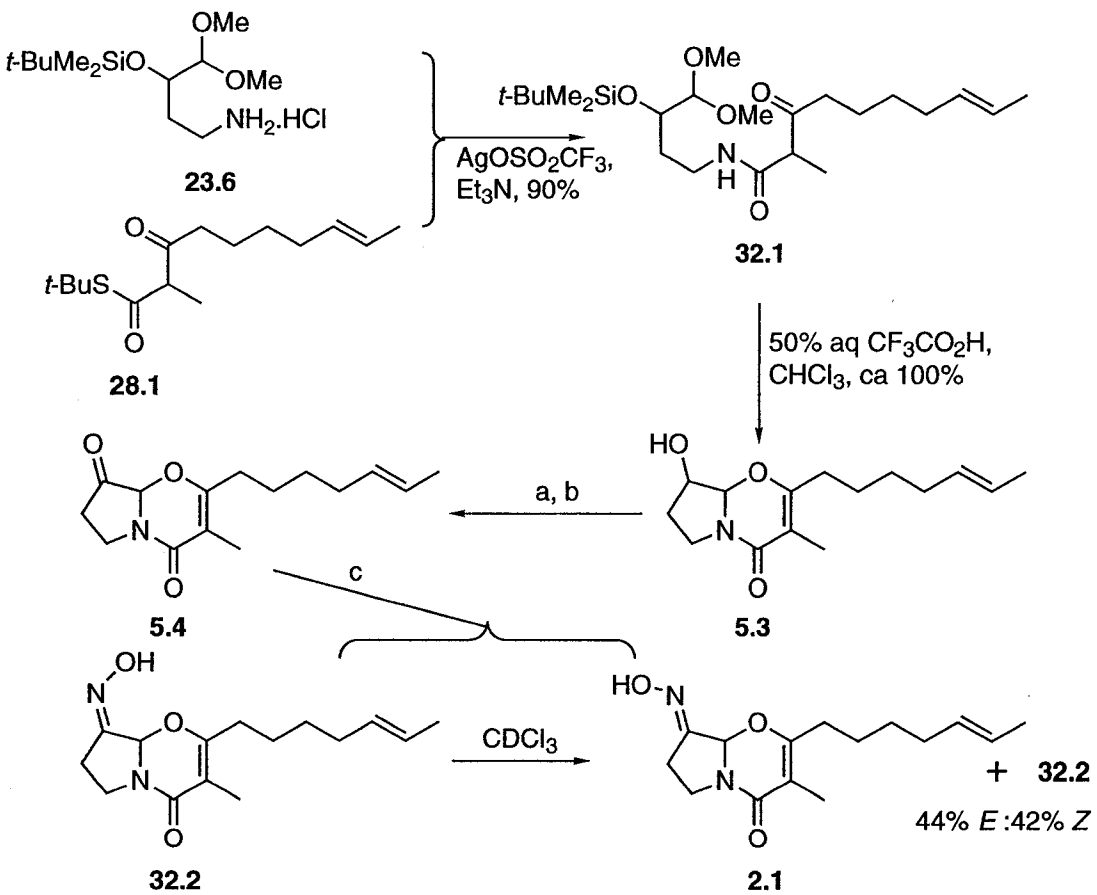


**29.5** **31.1** **31.2** **31.3** **31.4**

**Scheme 31**

**31.1**,[44] and simple displacement with malonate (**31.1** → **31.2**[45,46]), followed by base hydrolysis[46] and thermal decarboxylation[46] gave the required acid **31.4**. Although each of these steps had been reported in the literature, it is likely that the material described contained some of the *Z*-isomer.

The acid was converted into its imidazolide[43,47] by treatment with $Im_2C(O)$ and, without isolation, the imidazolide was added (Scheme 30) to the enolate (3 equiv.[43])



[a]Less polar isomer: Dess-Martin, 54% or 99% corrected for recovery of **5.3**.
[b]More polar isomer: $Pr_4NRuO_4$, 18% or 23% corrected for recovered **5.3**.
[c]$H_2NOH.HCl$, AcONa, 81% *E* isomer, 13% *Z* isomer

**Scheme 32**

prepared from thioester **30.1**[49] by treatment with LDA. In this way, β-keto thioester **28.1** was obtained in 64% yield (Scheme 30).

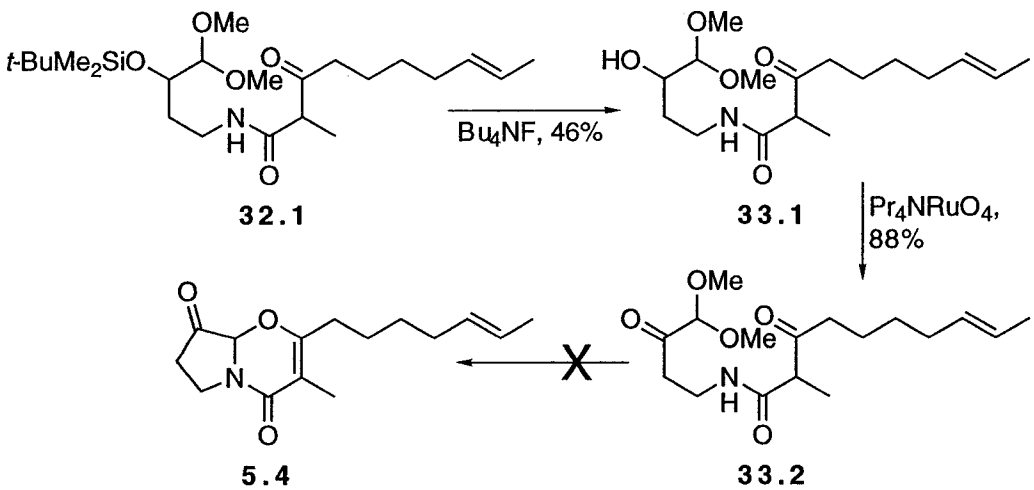
Coupling of **28.1** with the amino component **23.6** under conditions that had served well in the model study ($AgOSO_2CF_3$, $Et_3N$) was again successful (Scheme 32) and gave the β-keto amide **32.1** in 90% yield. Exposure to a mixture of 50% aqueous $CF_3CO_2H$ and $CHCl_3$ then resulted in the desired series of transformations (Scheme 32, hydrolysis, cyclization, and desilylation), giving rise to **5.3** as a 1:1 mixture of epimers in almost quantitative yield.

As in the model series, the next step – oxidation of the hydroxyl to a ketone – was not straightforward. The less polar alcohol gave ketone **5.4** in 54% yield (or 99%, corrected for recovered starting material) with the Dess-Martin reagent; $Pr_4NRuO_4$ destroyed the alcohol. The more polar alcohol could be oxidized by $Pr_4NRuO_4$ in 18% yield (or 23%, after correction for recovered starting material). This alcohol was inert to the Dess-Martin reagent. Thus, the total yield of ketone **5.4** is about 39%. Comparison of the $^1H$ NMR spectra of the two alcohols with those of the model compounds **27.1b** and **27.1a** suggests[50] that once again, the less polar isomer has the hydroxyl and angular hydrogen *syn*.

Ketone **5.4** was converted into a 4.3:1 ($^1H$ NMR) mixture of separable oximes. The major isomer (81% yield) proved to have the natural *E*-geometry (**2.1**). When the minor isomer **32.2** (13% yield) was stored for 2 days in $CDCl_3$, it was

converted into a mixture of the *E*- and *Z*-oximes, which were isolated in yields of 44% and 42%, respectively. Our racemic brevioxime was crystalline and its spectral properties were identical (within experimental error) with reported[2] values.

We tried to bypass the above difficulties in the oxidation step by performing the oxidation prior to the assembly of the bicyclic ring system. Desilylation of **32.1**



**Scheme 33**

gave alcohol **33.1** in 46% yield (Scheme 33). We deferred improvement of this yield until we had examined the subsequent steps. Alcohol **33.1** was oxidized to the corresponding ketone **33.2** but, unfortunately, we were unable to effect the hydrolysis-cyclization sequence under conditions that had worked previously or in the presence of $TsOH.H_2O$, or $Me_3SiCl$-NaI,[51] $SnCl_2$,[52] DDQ,[53] or Amberlyst 115.[54] Consequently, we decided to accept the synthesis we had already completed.

**Conclusion**

The above work illustrates the utility of the cyclization of an amide nitrogen onto an aldehyde carbonyl for generating certain nitrogen heterocycles. The method we have used to make brevioxime is convergent, and is clearly suitable for the synthesis of analogs.

As described in the review section, another synthesis very similar to ours was completed before our own work, but was not published until long after we had reported our results. In our studies we prepared two simplified models for brevioxime, and those experiments establish that our approach can be used to make analogs. Clearly the length of the $C_7$ substituent can be varied, as well as its constitution. It should also be possible to prepare *O*-alkyl derivatives of the oxime function, but we do not know if separation of *Z* and *E* isomers would then be a simple matter.

## EXPERIMENTAL SECTION

**General Procedures.** Unless stated to the contrary, the following conditions apply: Reactions were carried out under a slight static pressure of $N_2$ that had been purified by passage through a column (3.5 x 42 cm) of R-311 catalyst[55] and then through a similar column of Drierite. Glassware was dried in an oven for at least 3 h before use (120 °C) and either cooled in a desiccator over Drierite, or assembled quickly, sealed with rubber septa, and allowed to cool under a slight static pressure of $N_2$. Reaction mixtures were stirred by Teflon-coated magnetic stirring bars.

Hexane used for chromatography was distilled before use.

Products were isolated from solution by evaporation under water-aspirator vacuum at, or below, room temperature, using a rotary evaporator.

Cannula transfers were done under slight pressure ($N_2$), not by suction.

Commercial thin layer chromatography (TLC) plates (silica gel, Merck 60F-254) were used. Spots were detected by spraying the plate with a solution of phosphomolybdic acid[56] or *p*-anisaldehyde,[57] followed by charring with a heat gun, or by examination under UV light. Silica gel for flash chromatography was Merck type 60 (230-400 mesh).

Dry solvents were prepared under an inert atmosphere

and transferred by syringe or cannula. Dry THF and $Et_2O$ were distilled from sodium and benzophenone ketyl.

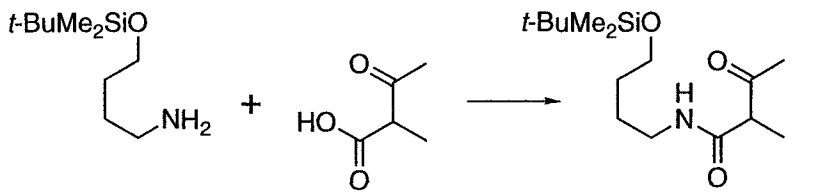
FT-IR measurements were recorded on a Nicolet 7000 FTIR instrument. Measurements were made as casts from the specified solvent using potassium bromide plates.

$^1H$ nuclear magnetic resonance spectra were recorded with Bruker AM-300 (at 300 MHz), Varian INOVA-300 (at 300 MHz), Bruker AM-360 (at 360 MHz) or Bruker AM-400 (at 400 MHz) spectrometers in the specified deuterated solvent at 27.2 °C. $^{13}C$ spectra were recorded with Bruker AM-300 (at 75.5 MHz) or Varian UNITY-500 (at 125 MHz) at 27.2 °C. The symbols s', d', t', and q' used for $^{13}C$ NMR signals indicate 0, 1, 2, or 3 attached hydrogens, respectively, which are assigned based on the APT experiment.

Mass spectra were recorded with AEI Models MS-12, MS-50 MS9 (modified), Kratos MS50 (modified) or Micromass ZabSpec Hybrid Sector-TOF mass spectrometers. For isotope peaks, high-resolution mass data were taken from the highest mass number peak shown in the spectrum.

Compounds isolated by flash chromatography were pure by TLC and, unless otherwise stated, also as judged by high field $^1H$ and $^{13}C$ NMR spectra.

***N*-[4-[[Dimethyl(1,1-dimethylethyl)silyl]oxy]-butyl]-2-methyl-3-oxobutanamide (18.3).**



**18.1** **18.4** **18.3**

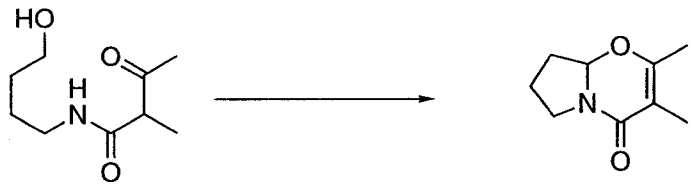
A cold (-78 °C) solution of β-keto acid **18.4**[21a] (310 mg, 2.66 mmol) in dry $CH_2Cl_2$ (0.50 mL) was added dropwise (ca 5 min) to a stirred and cooled (-78 °C) solution of the *O*-protected amino alcohol **18.1**[20] (300 mg, 1.48 mmol), DCC (335 mg, 1.62 mmol) and DMAP (30 mg, 0.24 mmol) in dry $CH_2Cl_2$ (1 mL). Stirring was continued overnight, but the cold bath was not recharged. The mixture was filtered and evaporated. Flash chromatography of the residue over silica gel (2 x 22 cm), using 1:1 EtOAc-hexanes, gave **18.3** (411 mg, 92%) as a colorless oil: FTIR ($CDCl_3$ cast) 3500-3150, 1724, 1641 $cm^{-1}$; $^1H$ NMR ($CDCl_3$, 400 MHz) δ 0.04 (s, 6 H), 0.88 (s, 9 H), 1.37 (d, $J$ = 7.0 Hz, 3 H), 1.47-1.60 (m, 4 H), 2.23 (s, 3 H), 3.20-3.30 (m, 2 H), 3.36 (q, $J$ = 7.2 Hz, 1 H), 3.62 (t, $J$ = 5.9 Hz, 2 H), 6.28 (br s, 1 H); $^{13}C$ NMR ($CDCl_3$, 100.6 MHz) δ -5.3 (q'), 14.7 (q'), 18.4 (s'), 26.0 (q'), 26.1 (t'), 28.6 (q'), 30.0 (t'), 39.5 (d'), 55.1 (t'), 62.7 (t'), 169.3 (s'), 207.6 (s'); exact mass $m/z$ calcd for $C_{15}H_{31}NO_3Si$ 301.2073, found 301.2074. This experiment was done several times; the yields varied between 67% and 92%.

**_N_-(4-Hydroxybutyl)-2-methyl-3-oxobutanamide (18.5).**

**18.3** **18.5**

$Bu_4NF$ (1.0 M in THF, 0.81 mL, 0.81 mmol) was added to a stirred solution of β-keto amide **18.3** (222 mg, 0.74 mmol) and glacial AcOH (0.09 mL, 1.47 mmol) in dry THF (2.50 mL). The mixture was warmed to 45 °C (oil bath) for 14 h, and then evaporated. Flash chromatography of the residue over silica gel (2 x 15 cm), using 1:9 MeOH-$Et_2O$, gave **18.5** (110 mg, 80%) as a colorless oil: FTIR ($CDCl_3$ cast) 3650-3150, 1720, 1647 $cm^{-1}$; $^1H$ NMR ($CDCl_3$, 400 MHz) δ 1.37 (d, $J$ = 7.3 Hz, 3 H), 1.54-1.66 (m, 4 H), 2.24 (s, 3 H), 2.20-2.28 (br s, 1 H), 3.22-3.32 (m, 2 H), 3.38 (q, $J$ = 7.2 Hz, 1 H), 3.66 (t, $J$ = 5.8 Hz, 2 H), 6.54 (br s, 1 H); $^{13}C$ NMR ($CDCl_3$, 100.6 MHz) δ 14.7 (q'), 26.1 (t'), 28.6 (q'), 29.7 (t'), 39.4 (t'), 55.0 (d'), 62.3 (t'), 169.6 (s'), 207.7 (s'); exact mass $m/z$ calcd for $C_9H_{17}NO_3$ 187.1209, found 187.1212.

**6,7,8,8a-Tetrahydro-2,3-dimethyl-4*H*-pyrrolo[2,1-b][1,3]oxazine-4-one (18.6).**



**18.5** **18.6**

*N*-Methylmorpholine *N*-oxide (24.0 mg, 0.20 mmol), $Pr_4NRuO_4$ (2.4 mg, 0.007 mmol) and crushed 4Å molecular sieves (68 mg) were added to a stirred solution of alcohol **18.5** (25.5 mg, 0.14 mmol) in dry $CH_2Cl_2$ (0.8 mL). Stirring was continued for 2 h, and the mixture was then loaded onto a silica gel column (0.8 x 14 cm). Flash chromatography, using 99:1 EtOAc-hexanes, gave **18.6** (8.2 mg, 33%) as an unstable, colorless oil: FTIR ($CDCl_3$ cast) 1655 $cm^{-1}$; $^1H$ NMR ($CDCl_3$, 360 MHz) δ 1.80 (s, 3 H), 1.81-1.92 (m, 1 H), 1.93 (s, 3 H), 1.94-2.16 (m, 2 H), 2.22-2.35 (m, 1 H), 3.38-3.48 (m, 1 H), 3.70-3.78 (m, 1 H), 5.24 (t, $J$ = 5.2 Hz, 1 H); $^{13}C$ NMR ($CDCl_3$, 50.3 MHz) δ 10.3 (q'), 16.7 (q'), 21.9 (t'), 31.6 (t'), 44.3 (t'), 87.4 (d'), 106.6 (s'), 160.2 (s'); exact mass *m/z* calcd for $C_9H_{13}NO_2$ 167.0946, found 167.0946.

**1,1-Dimethoxy-2,3-epoxypropane (23.3).**

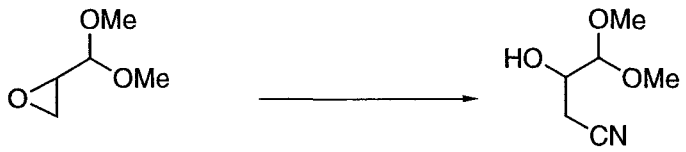
**23.2** **23.3**

The method[29] for the corresponding diethyl acetal was followed. Ice-cold HOCl[58] (79.0 mL) was added in three portions to a stirred and cooled (0 °C) emulsion of acrolein dimethyl acetal (**23.2**) (7.36 g, 72.06 mmol) in water (30.0 mL). The temperature of the mixture was kept below 14 °C, and cooling and stirring were continued for 25 min after the end of the addition. The cold bath was removed and $NaHCO_3$ (4.5 g, 42.4 mmol) and 1 M aqueous $Na_2S_2O_3$ (3.0 mL, 3.0 mmol) were added to the mixture, which was then saturated with NaCl and extracted with $CH_2Cl_2$. The combined organic extracts were dried ($MgSO_4$) and evaporated *in vacuo* to give the crude chlorohydrin, which was used directly in the next step.

Powdered NaOH (5.50 g, 137.5 mmol) was tipped into a stirred solution of the crude chlorohydrin in dry PhH (80.0 mL) (protection from moisture by $CaSO_4$ guard tube). The mixture was refluxed for 30 min, removed from the oil bath, stirred for 1 h, and filtered. Spinning band distillation of the filtrate gave **23.3** (6.171 g, 72%) as a pale yellow oil: FTIR ($CDCl_3$ cast) 2998, 1255 $cm^{-1}$; $^1H$ NMR ($CDCl_3$, 300 MHz) $\delta$ 2.71-2.79 (m, 2 H), 3.04-3.10 (m, 1 H), 3.40 (s, 3 H), 3.42 (s, 3 H), 4.23 (d, $J$ = 4.2 Hz, 1 H); $^{13}C$ NMR ($CDCl_3$, 75.5 MHz)

δ 43.6 (t'), 51.2 (d' or q'), 53.8 (d' or q'), 54.5 (d' or q'), 103.0 (d'); exact mass *m/z* calcd for $C_5H_9O_3$ (M - H) 117.0552, found 117.0553.

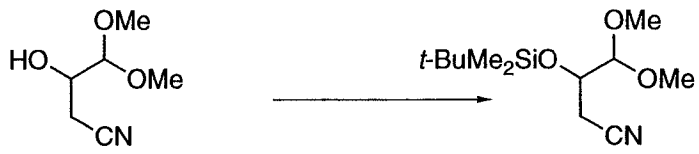
**3-Hydroxy-4,4-dimethoxybutanenitrile (18).**



**23.3** **23.4**

A solution of KCN (414 mg, 6.36 mmol) in water (4 mL) was added to a stirred solution of epoxide **23.3** (501 mg, 4.24 mmol) in EtOH (10 mL).[30] Stirring was continued for 24 h, by which time all the starting material had reacted (TLC control, silica, 1:3 EtOAc-hexanes). The solvent was evaporated and the residue was filtered through a pad (5 x 4 cm) of silica gel, using $CH_2Cl_2$. Evaporation of the filtrate gave **23.4** (469 mg, 76%) as a thick, colorless oil: FTIR (neat film) 3700-3200, 2252 $cm^{-1}$; $^1H$ NMR ($CDCl_3$, 200 MHz) δ 2.49-2.68 (m, 2 H), 3.10 (br s, 1 H), 3.45 (s, 3 H), 3.46 (s, 3 H), 3.83-3.86 (m, 1 H), 4.25 (d, *J* = 5.6, 1 H); $^{13}C$ NMR ($CDCl_3$, 75.5 MHz) δ 20.8 (t'), 55.2 (q'), 56.1 (q'), 67.5 (d'), 105.4 (d'), 117.6 (s'); exact mass *m/z* calcd for $C_6H_{10}NO_3$ 144.0661 (M - H), found 144.0660.

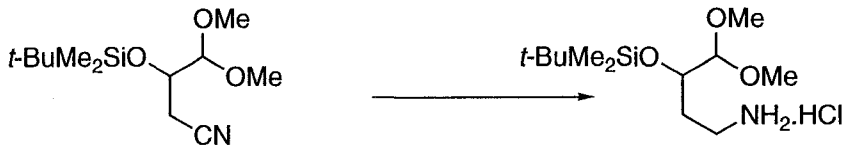
**3-[[Dimethyl(1,1-dimethylethyl)silyl]oxy]-4,4-dimethoxybutanenitrile (23.5).**



**23.4** **23.5**

*t*-$BuMe_2SiCl$ (2.252 g, 14.9 mmol) and DMAP (36.5 mg, 0.30 mmol) were tipped into a stirred and cooled (0 °C) solution of nitrile **23.4** (1.083 g, 7.469 mmol) and $Et_3N$ (1.35 mL, 10.4 mmol) in dry $CH_2Cl_2$ (15 mL). Stirring at 0 °C was continued for 15 min; the mixture was allowed to warm to room temperature, and was then refluxed for 12 h. Evaporation of the solvent and flash chromatography of the residue over silica gel (3.5 x 20 cm), using 1:3 EtOAc-hexanes, gave **23.5** [1.272 g, 65% (or 81%, after correction for recovered **23.4** (0.214 g)] as a colorless oil: FTIR ($CDCl_3$ cast) 2250 $cm^{-1}$; $^1H$ NMR ($CDCl_3$, 360 MHz) δ 0.12 (s, 3 H), 0.15 (s, 3 H), 0.92 (s, 9 H), 2.50-2.63 (m, 2 H), 3.45 (s, 3 H), 3.48 (s, 3 H), 3.85-3.89 (m, 1 H), 4.19 (d, $J$ = 4.9 Hz, 1 H); $^{13}C$ NMR ($CDCl_3$, 50.5 MHz) δ -5.0 (q'), -4.6 (q'), 18.0 (s'), 21.8 (t'), 25.6 (q'), 56.5 (q'), 56.6 (q'), 69.8 (d'), 106.7 (d'), 118.0 (s'); exact mass (HR electrospray) $m/z$ calcd for $C_{12}H_{25}NNaO_3Si$ 282.1501, found 282.1496.

**3-[[Dimethyl(1,1-dimethylethyl)silyl]oxy]-4,4-dimethoxybutanamine hydrochloride (23.6).**



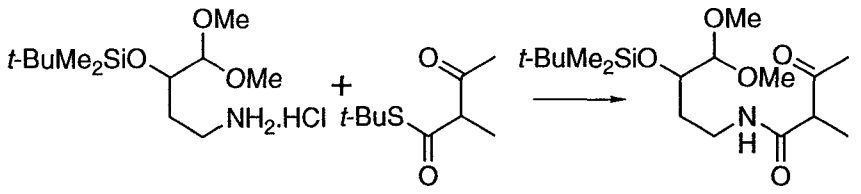
**23.5** **23.6**

Adams catalyst ($PtO_2$) (82 mg) was suspended in dry EtOH (40 mL, distilled from $Mg/I_2$), and a solution of nitrile **23.5** (934 mg, 3.60 mmol) in dry EtOH (10 mL) was added to the suspension, followed by bench $CHCl_3$ (1.85 mL). The mixture was shaken under $H_2$ (50 psi, Parr bottle) at room temperature for 24 h. The catalyst was filtered off and the filtrate was evaporated. The residue was kept under oil pump vacuum for 24 h to give **23.6** (1.08 g, 100%). Recrystallization from $CH_2Cl_2$-petroleum ether (bp 60-70 °C) gave **23.6** as white flakes in quantitative yield. The material had: mp 118-122 °C; FTIR (USCOPE) 3460, 3300-2500, 2049 $cm^{-1}$; $^1H$ NMR ($CDCl_3$, 300 MHz) $\delta$ 0.10 (s, 3 H), 0.11 (s, 3 H), 0.89 (s, 9 H), 1.72 (br s, 2 H), 1.93-2.14 (m, 2 H), 3.10-3.23 (m, 2 H), 3.44 (s, 3 H), 3.52 (s, 3 H), 3.85-3.89 (m, 1 H), 4.18 (d, $J$ = 3.9 Hz, 1 H), 8.20 (br s, 1 H); $^{13}C$ NMR ($CDCl_3$, 100.5 MHz) $\delta$ -4.7 (q'), 18.0 (s'), 25.8 (q'), 29.4 (t'), 36.0 (t'), 56.4 (q'), 57.4 (q'), 71.0 (d'), 107.6 (d'); exact mass (HR electrospray) $m/z$ calcd for $C_{12}H_{30}NO_3Si$ 264.1995, found 264.1990.

The yield in this experiment varied between 60% and 75%.

In the above case, the recovered catalyst appeared to be very active, and burned on exposure to air.

***N*-[3-[[Dimethyl(1,1-dimethylethyl)silyl]oxy]-4,4-dimethoxybutyl]-2-methyl-3-oxobutanamide (25.3).**



**23.6** **25.2** **25.3**

$Et_3N$ (0.26 mL, 1.88 mmol) was added to a stirred solution of amine hydrochloride **23.6** (282 mg, 0.94 mmol) and thioester **25.2**[37] (177 mg, 0.94 mmol) in dry THF (2 mL). $AgOSO_2CF_3$ (488 mg, 1.88 mmol) was tipped into the mixture. After 40 min, the reaction was complete (TLC control, silica, 1:1 EtOAc-hexanes). The brown mixture was poured into a small volume of hexanes above a column of silica gel (2 x 15 cm), and the column was developed in the standard manner for flash chromatography, using 1:1 EtOAc-hexanes, to give **25.3** (251 mg, 79%) as a pale yellow oil: FTIR ($CDCl_3$ cast) 3500-3150, 1722, 1644 $cm^{-1}$; $^1H$ NMR ($CDCl_3$, 360 MHz) $\delta$ 0.07 (s, 3 H), 0.08 (s, 3 H), 0.89 (s, 9 H), 1.36 (d, $J$ = 7 Hz, 3 H), 1.68-1.83 (m, 2 H), 2.22 (s, 3 H), 3.28-3.38 (m, 3 H), 3.42 (d, $J$ = 0.6 Hz, 3 H), 3.44 (d, $J$ = 0.7 Hz, 3 H), 3.70-3.76 (m, 1 H), 4.15 (dd, $J$ = 7.0, 0.7 Hz, 1 H), 6.45 (br s, 1 H); $^{13}C$ NMR ($CDCl_3$, 50.3 MHz) (mixture of rotamers) $\delta$ -4.9 (q'),

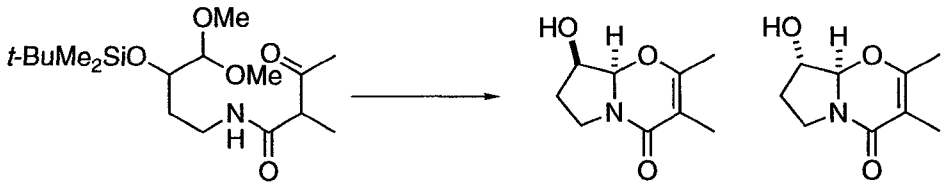
**(8α,8aα)-6,7,8,8a-Tetrahydro-8-hydroxy-2,3-dimethyl-4*H*-pyrrolo[2,1-b][1,3]oxazine-4-one (27.1b) and (8α,8aβ)-6,7,8,8a-Tetrahydro-8-hydroxy-2,3-dimethyl-4*H*-pyrrolo[2,1-b][1,3]oxazine-4-one (27.1a).**



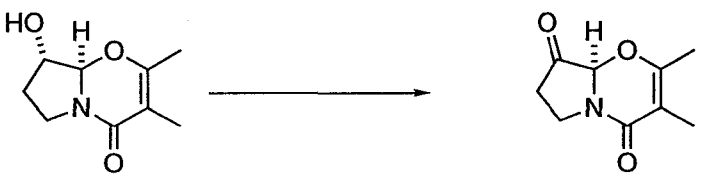
**25.3** **27.1a** **27.1b**

Aqueous $CF_3CO_2H$ (50%, 2.0 mL) was added to a stirred solution of β-keto amide **25.3** (187.5 mg, 0.518 mmol) in $CHCl_3$ (4 mL). Stirring was continued for 48 h and the solvent was then evaporated. The residue was kept under oil pump vacuum for 24 h, after which time a white solid was obtained. Flash chromatography over silica gel (1.2 x 20 cm), using 1:1 EtOAc-$Et_2O$ and then 2:9:9 MeOH-EtOAc-$Et_2O$, gave the less polar isomer **27.1b** (38.4 mg, 37%) and the more polar isomer **27.1a** (36.3 mg, 35%) as white crystalline solids. Compound **27.1b** had: mp 104-106 °C; FTIR ($CDCl_3$ cast) 3600-3100, 1645, 1450

$cm^{-1}$; $^1H$ NMR ($CDCl_3$, 400 MHz) δ 1.79 (d, *J* = 0.5 Hz, 3 H), 1.87-1.98 (m, 1 H), 1.95 (d, *J* = 0.6 Hz, 3 H), 2.21-2.29 (m, 2 H), 3.59-3.71 (m, 2 H), 4.45-4.52 (m, 1 H), 5.07 (d, *J* = 3.8 Hz, 1 H); $^{13}C$ NMR ($CDCl_3$, 100.6 MHz) δ 10.2 (q'), 16.7 (q'), 30.0 (t'), 41.7 (t'), 75.3 (d'), 92.1 (d'), 106.7 (s'), 159.8 (s'), 163.1 (s'); exact mass *m/z* calcd for $C_9H_{13}NO_3$ 183.0895, found 183.0897. The structure was confirmed by X-ray analysis (see Appendix).

Compound **27.1a** had: mp 118-120 °C; FTIR ($CDCl_3$ cast) 3600-3100, 1651, 1458 $cm^{-1}$; $^1H$ NMR ($CDCl_3$, 400 MHz) δ 1.80 (d, *J* = 0.8 Hz, 3 H), 1.94-2.14 [m including d at δ 1.98 (*J* = 0.9 Hz), 5 H in all], 2.44-2.48 (m, 1 H), 3.52-3.60 (m, 1 H), 3.68-3.78 (m, 1 H), 4.42-4.47 (m, 1 H), 5.24 (d, *J* = 3.5 Hz, 1 H); $^{13}C$ NMR ($CDCl_3$, 100.6 MHz) δ 10.2 (q'), 16.8 (q'), 29.3 (t'), 41.7 (t'), 70.6 (d'), 87.6 (d'), 106.9 (s'), 159.0 (s'), 162.9 (s'); exact mass *m/z* calcd for $C_9H_{13}NO_3$ 183.0895, found 183.0896.

**6,7-Dihydro-2,3-dimethyl-4*H*-pyrrolo[2,1-b][1,3]-oxazine-4,8(8a*H*)-dione (27.2) from less polar alcohol.**

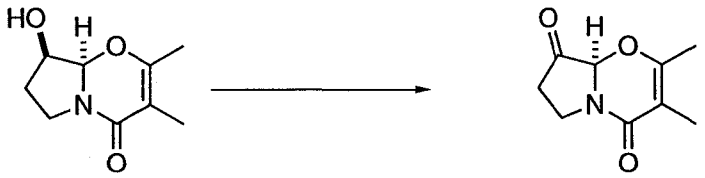


**27.1b** **27.2**

Dess-Martin periodinane (17.8 mg, 0.04 mmol) was added

to a solution of the less polar isomer **27.1b** (5.9 mg, 0.032 mmol) in dry $CH_2Cl_2$ (1 mL). The mixture was stirred for 2 h, and then applied directly to a silica gel column (0.8 x 13 cm) made up with 99:1 EtOAc-hexanes. Flash chromatography, using the same solvent, gave **27.2** (2.5 mg, 42%) as a colorless oil: FTIR ($CDCl_3$ cast) 1772, 1659 $cm^{-1}$; $^1H$ NMR ($CD_2Cl_2$, 400 MHz) δ 1.79 (d, *J* = 0.8 Hz, 3 H), 2.00 (d, *J* = 0.9 Hz, 3 H), 2.60-2.78 (m, 2 H), 3.52-3.62 (m, 1 H), 4.00-4.10 (m, 1 H), 5.06 (s, 1 H); $^{13}C$ NMR ($CD_2Cl_2$, 100.6 MHz) δ 10.3 (q'), 16.9 (q'), 34.1 (t'), 38.3 (t'), 82.2 (d'), 107.5 (s'), 160.0 (s'), 163.4 (s'), 204.9 (s'); exact *m/z* calcd for $C_9H_{11}NO_3$ 181.0739, found 181.0738.

**6,7-Dihydro-2,3-dimethyl-4*H*-pyrrolo[2,1-b][1,3]-oxazine-4,8(8a*H*)-dione (27.2) from more polar alcohol.**

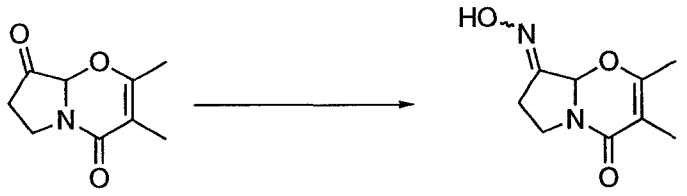


**27.1a** **27.2**

*N*-Methylmorpholine *N*-oxide (8.64 mg, 0.074 mmol), $Pr_4NRuO_4$ (0.9 mg, 0.0026 mmol) and crushed 4Å molecular sieves (25 mg) were added in succession to a stirred solution of the more polar isomer **27.1a** (9.0 mg, 0.049 mmol) in dry 1:1 $CH_2Cl_2$-MeCN (0.5 mL). Stirring was continued for 1.5 h, and the mixture was then loaded onto a silica gel column (0.8 x

14 cm) made up with 99:1 EtOAc-hexanes. Flash chromatography, using the same solvent, gave **27.2** [4.2 mg, 46% or 84% after correction for recovered starting material (4.0 mg)] as a colorless oil, spectroscopically identical to the compound obtained from the other isomer.

**6,7-Dihydro-2,3-dimethyl-4*H*-pyrrolo[2,1-b][1,3]-oxazine-4,8(8a*H*)-dione 8-oxime (19.2).**



**27.2** **19.2**

A solution of $NH_2OH.HCl$ (8.8 mg, 0.127 mmol) and AcONa (17.6 mg, 0.129 mmol) in water (0.2 mL) was added to a stirred solution of ketone **27.2** (4.4 mg, 0.024 mmol) in EtOH (0.2 mL). Stirring was continued for 3.5 h, and the solvent was then evaporated. Flash chromatography of the residue over silica gel (0.8 x 20 cm), using 99:1 EtOAc-hexanes, gave the less polar *E* oxime **15a** (3.5 mg, 74%) and the more polar *Z* oxime **15b** (0.3 mg, 6.3%) as white solids. Compound **15a** had: mp 176-178 °C and then solidifies, but does not melt again; FTIR ($CH_2Cl_2$ cast) 3600-2950, 1643 $cm^{-1}$; $^1H$ NMR ($CD_2Cl_2$, 400 MHz) $\delta$ 1.79 (d, $J$ = 0.8 Hz, 3 H), 1.98 (d, $J$ = 0.9 Hz, 3 H), 2.74-2.98 (m, 2 H), 3.41-3.50 (m, 1 H), 3.94-4.04 (m, 1 H), 5.59 (d, $J$ = 1.5 Hz, 1 H), 8.40 (s, 1 H); $^{13}C$ NMR ($CD_2Cl_2$,

100.6 MHz) δ 10.3 (q'), 16.9 (q'), 23.9 (t'), 41.9 (t'), 84.5 (d'), 107.4 (s'), 158.3 (s'), 160.7 (s'), 163.3 (s'); exact mass *m/z* calcd for $C_9H_{12}N_2O_3$ 196.0848, found 196.0843.

Compound **15b** had: FTIR ($CD_2Cl_2$ cast) 3500-3000, 1640 $cm^{-1}$; $^1H$ NMR ($CD_2Cl_2$, 400 MHz) δ 1.78 (d, *J* = 0.9 Hz, 3 H), 1.98 (d, *J* = 0.8 Hz, 3 H), 2.62-2.71 (m, 1 H), 2.78-2.90 (m, 1 H), 3.26-3.34 (m, 1 H), 4.00-4.08 (m, 1 H), 5.87 (d, *J* = 1.4 Hz, 1 H), 7.56 (s, 1 H); $^{13}C$ NMR ($CD_2Cl_2$, 100.6 MHz) δ 10.4, 17.0, 27.4, 41.7, 80.1, 107.2, 157.5, 160.5, 162.8; exact mass *m/z* calcd for $C_9H_{12}N_2O_3$ 196.0848, found 196.0849. The mp was not measured.

**(*E*)-4-Hexenol (29.4).**[41]

**29.2** **29.4**

Freshly cut Na (2.43 g, 105 mmol) was powdered by heating in xylenes (dried over 4Å molecular sieves, 75 mL) at 120 °C with stirring. The resulting suspension was cooled, and the Na powder was washed with dry $Et_2O$ under $N_2$ and then covered with dry $Et_2O$ (20 mL), the washings being removed each time by suction through a cannula. A few drops of a solution of 3-chloro-2-methyl-tetrahydropyran[41b] (**Hazard warning**) (6.00 g, 42.3 mmol) in dry $Et_2O$ (20 mL) was added to the Na with vigorous magnetic stirring. After a few min,

a vigorous reaction occurred and a purple mixture was formed. The remaining pyran solution was added at such a rate as to maintain gentle reflux. The blue mixture was left for 28 h at room temperature, and the excess of Na was carefully destroyed ($N_2$ atmosphere) with wet $Et_2O$, followed by water. The ether layer was separated and the aqueous layer was extracted with $Et_2O$. The combined organic extracts were washed successively with 5% aqueous HCl (50 mL) and brine, and then dried ($MgSO_4$). The solvent was removed by distillation at 1 atm, and the oily residue was distilled to yield **29.4** (3.99 g, 94%) as a 95:5 mixture of *E* and *Z* isomers, bp 85-90 °C (water pump vacuum). Spinning band distillation at 158-159 °C (1 atm) gave pure (GC-MS) (*E*)-hex-4-enol as a colorless liquid in 20% yield: FTIR (neat film) 3600-3100 $cm^{-1}$; $^1H$ NMR ($CDCl_3$, 400 MHz) δ 1.56-1.66 [m containing d at δ 1.63 ($J$ = 6.2 Hz), 5 H in all], 1.90 (s, 1 H), 2.01-2.09 (m, 2 H), 3.61 (t, $J$ = 6.5 Hz, 2 H), 5.37-5.50 (m, 2 H); $^{13}C$ NMR ($CDCl_3$, 50.3 MHz) δ 17.8 (q'), 28.8 (t'), 32.4 (t'), 62.4 (t'), 125.4 (d'), 130.6 (d'); exact mass *m/z* calcd for $C_6H_{12}O$ 100.0888, found 100.0887.

**Methanesulfonic acid (*E*)-4-hexenyl ester (29.5).**[44]

**29.4** **29.5**

$MeSO_2Cl$ (1.81 mL, 23.3 mmol) was added dropwise to a stirred and cooled (0 °C) solution of (*E*)-4-hexenol (**29.4**)

(1.915 g, 19.2 mmol) and $Et_3N$ (3.33 mL, 23.2 mmol) in dry THF (400.0 mL). Stirring at 0 °C was continued for 40 min, the cold bath was removed, and stirring was continued for 30 min. The mixture was quenched with water (25 mL) and diluted with $CH_2Cl_2$ (100 mL). The organic phase was separated and the aqueous layer was extracted with $CH_2Cl_2$. The combined organic extracts were dried ($MgSO_4$), and evaporated to give crude **29.5** (3.409 g, 100%) as a pale yellow oil, suitable for the next step. Pure mesylate, obtained by flash chromatography over silica gel (3.5 x 16 cm), using 1:4 EtOAc-hexanes had: FTIR ($CDCl_3$ cast) 1352, 1173 $cm^{-1}$; $^1H$ NMR ($CDCl_3$, 400 MHz) δ 1.62-1.64 (m, 3 H), 1.74-1.82 (m, 2 H), 2.05-2.11 (m, 2 H), 2.98 (s, 3 H), 4.19 (dt, *J* = 6.5, 0.94 Hz, 2 H), 5.31-5.41 (m, 1 H), 5.42-5.52 (m, 1 H); $^{13}C$ NMR ($CDCl_3$, 100.6 MHz) δ 17.8 (q'), 28.2 (t'), 28.8 (t'), 37.3 (q'), 69.5 (t'), 126.6 (d'), 129.1 (d'); exact mass *m/z* calcd for $C_7H_{14}O_3S$ 178.0664, found 178.0663.

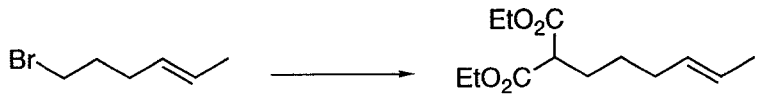
**(*E*)-6-Bromo-2-hexene (31.1).**[44]

**29.5** **31.1**

Anhydrous LiBr (dried overnight at 110 °C under oil pump vacuum, 2.94 g, 33.8 mmol) was tipped into a stirred solution of crude mesylate **29.5** (2.008 g, 11.28 mmol) in dry THF (40.0 mL). The resulting solution was refluxed for 3.5 h, by which

time all starting material had been consumed (TLC control, silica gel, 1:4 EtOAc-hexanes). The mixture was cooled and added to pentane (200 mL), washed with water, dried ($MgSO_4$) and evaporated. The residue was distilled to give **31.1** (1.605 g), as a colorless, acrid liquid: bp 165 °C (760 mm Hg); FTIR ($CDCl_3$ cast) 1779, 1740 $cm^{-1}$; $^1H$ NMR ($CDCl_3$, 400 MHz) δ 1.63-167 (m, 3 H), 1.86-1.94 (m, 2 H), 2.10-2.70 (m, 2 H), 3.40 (t, *J* = 6.8 Hz, 2 H), 5.32-5.42 (m, 1 H), 5.45-5.55 (m, 1 H); $^{13}C$ NMR ($CDCl_3$, 100.6 MHz) δ 17.9 (q'), 30.9 (t'), 32.5 (t'), 33.3 (t'), 126.4 (d'), 129.2 (d'); exact mass *m/z* calcd for $C_6H_{11}{}^{79}Br$ 162.00446, found 162.0044.

**Diethyl (*E*)-2-(4-Hexenyl)propanedioate (31.2).**[45,46]

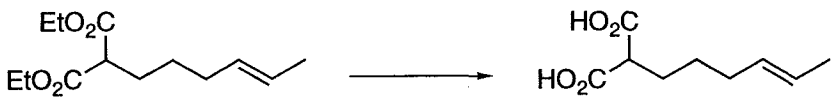


**31.1** **31.2**

(*E*)-6-Bromohex-2-ene (**31.1**) (1.515 g, 9.30 mmol) in dry EtOH (5.0 mL) was added dropwise to a stirred solution of $NaCH(CO_2Et)_2$ [prepared from $CH_2(CO_2Et)_2$ (1.53 mL, 11.2 mmol) and Na (257 mg, 11.6 mmol) in dry EtOH (6.0 mL) at 50 °C]. The resulting mixture was refluxed under Ar for 3 h, and then cooled. Most of the solvent was evaporated, and the residue was taken up in pentane (100 mL), washed with water, dried ($MgSO_4$), evaporated, and fractionally distilled to give **31.2** (1.636 g, 72%) as a colorless oil: bp 172 °C (water-pump

vacuum); FTIR ($CDCl_3$ cast) 1734 $cm^{-1}$; $^1H$ NMR ($CDCl_3$, 360 MHz) δ 1.24 (t, $J$ = 7.2 Hz, 6 H), 1.31-1.40 (m, 2 H), 1.60-1.62 (m, 3 H), 1.87 (q, $J$ = 7.9 Hz, 2 H), 1.94-2.02 (m, 2 H), 3.29 (t, $J$ = 7.6 Hz, 1 H), 4.17 (q, $J$ = 7.1 Hz, 4 H), 5.30-5.47 (m, 2 H); $^{13}C$ NMR ($CDCl_3$, 50.3 MHz) δ 14.1 (q'), 17.9 (q'), 27.2 (t'), 28.2 (t'), 32.1 (t'), 51.9 (d'), 61.2 (t'), 125.5 (d'), 130.5 (d'), 169.5 (s'); exact mass $m/z$ calcd for $C_{13}H_{22}O_4$ 242.1518, found 242.1516.

**(*E*)-2-(4-Hexenyl)propanedioic acid (31.3).**[46]

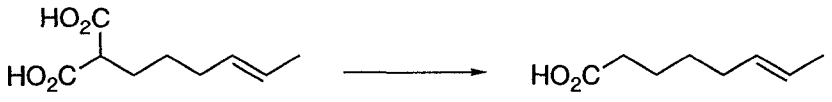


**31.2** **31.3**

Diethyl (*E*)-hex-4-enylmalonate (**31.2**) (1.64 g, 6.76 mmol) was added to a stirred and cooled (0 °C) solution of KOH (1.51 g, 27.3 mmol) in water (26 mL), followed by sufficient EtOH (12 mL) to produce homogeneity. After 24 h, the solution was washed with $CH_2Cl_2$ and the aqueous layer was cooled (0 °C) and acidified to pH ca 2 (universal indicator) with concentrated HCl. The precipitated diacid **31.3** was extracted with $Et_2O$, and the combined extracts were dried ($MgSO_4$) and evaporated to give crude **31.3** (1.248 g, 99%), which was recrystallized from PhH to give pure **31.3** (739 mg, 59% recovery) as a white solid: mp 110-112 °C (lit.[46] 115-116 °C); FTIR (USCOPE) 3400-2400 $cm^{-1}$, 1709 $cm^{-1}$; $^1H$ NMR (DMSO-$d_6$, 360 MHz) δ 1.40-1.51 (m, 2 H), 1.65 (dd, $J$ = 5.5, 0.6 Hz, 3

H), 1.91-1.97 (m, 2 H), 2.00-2.06 (m, 2 H), 3.44 (t, $J$ = 7.4 Hz, 1 H), 5.33-5.51 (m, 2 H), 10.3-11.0 (br s, 2 H); $^{13}C$ NMR (DMSO-$d_6$, 50.3 MHz) δ 17.7 (q'), 26.7 (t'), 27.9 (t'), 31.7 (t'), 51.4 (d'), 124.8 (d'), 130.8 (d'), 170.9 (s'); exact mass $m/z$ calcd for $C_9H_{14}O_4$ 186.0892, found 186.0888.

**(*E*)-6-Octenoic acid (31.4).**[46]

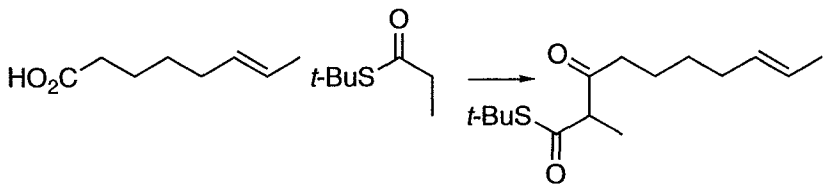


**31.3** **31.4**

A round-bottomed 50-mL flask containing (*E*)-hex-4-enylmalonic acid (**31.3**) (943 mg, 5.07 mmol) was lowered into a preheated (155-160 °C) oil bath. After 5.5 h, the flask was cooled and its contents were dissolved in saturated aqueous $NaHCO_3$ (15 mL). The resulting solution was washed with $Et_2O$ and the aqueous layer was acidified with concentrated HCl. The precipitated acid was extracted with $Et_2O$, and the combined extracts were dried ($MgSO_4$) and evaporated to give the crude acid. Flash chromatography over silica gel (2 x 20 cm), using 1:1 $Et_2O$-hexanes, gave **31.4** (676 mg, 93%) as a colorless oil: FTIR ($CDCl_3$ cast) 3600-2300, 1706 $cm^{-1}$; $^1H$ NMR ($CDCl_3$, 400 MHz) δ 1.35-1.48 (m, 2 H), 1.58-1.68 (m, 5 H), 1.96-2.04 (m, 2 H), 2.35 (t, $J$ = 7.5 Hz, 2 H), 5.33-5.50 (m, 2 H); $^{13}C$ NMR ($CDCl_3$, 100.6 MHz) δ 17.9 (q'), 24.1 (t'), 28.9 (t'), 32.1 (t'), 33.8 (t'), 125.3 (d'), 130.8 (d'), 179.5 (s'); exact mass $m/z$ calcd for $C_8H_{14}O_2$

142.0994, found 142.0991.

***S*-(1,1-Dimethylethyl) (*E*)-2-Methyl-3-oxo-8-decenethioate (28.1).**



**31.4** **30.1** **28.1**

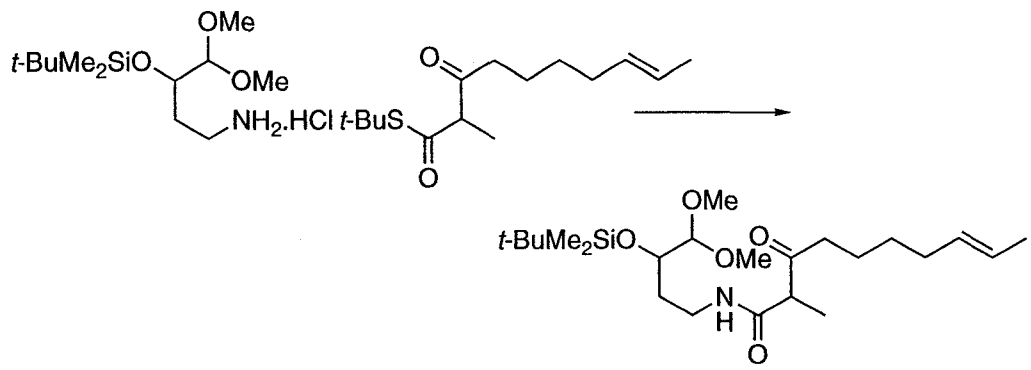
1,1'-Carbonyldiimidazole (293 mg, 1.81 mmol) was tipped into a stirred and cooled (0 °C) solution of (*E*)-6-octenoic acid (**31.4**) (233 mg, 1.64 mmol) in dry THF (0.8 mL). Brisk evolution of gas occurred. When the reaction had subsided, the cold bath was removed and stirring was continued for 30 min.

In the meantime the lithium enolate of thioester **30.1**[49] was prepared by slow addition of LDA [made by dropwise addition of BuLi (2.5 M in hexanes, 1.97 mL, 4.92 mmol) to *i*-$Pr_2NH$ (0.69 mL, 4.92 mmol) in dry THF (1.0 mL) at -78 °C, followed by warming to 0 °C (transfer to an ice bath) for 5 min, and recooling to -78 °C] to a stirred and cooled (-78 °C) solution of **30.1** (719 mg, 4.92 mmol) in THF (1 mL). After 15 min a yellow solution was obtained.

The imidazolide solution made in the first part of this experiment was cooled to -78 °C and transferred by cannula over 10 min into the stirred and cooled (-78 °C) enolate

solution. Stirring at -78 °C was continued for 30 min, the cold bath was removed, and stirring was continued for a further 5 min. The reaction was quenched with saturated aqueous $NH_4Cl$ (2 mL) and the mixture was diluted with $Et_2O$ (30 mL). The aqueous layer was extracted with $Et_2O$, and the combined organic extracts were dried ($MgSO_4$) and evaporated to give a yellow oil. Flash chromatography over silica gel (2 x 24 cm), using with 1:24 $Et_2O$-petroleum ether (bp 60-70 °C) gave **28.1** (287.2 mg, 64%) as a colorless oil: FTIR ($CDCl_3$ cast) 1725, 1673 $cm^{-1}$; $^1H$ NMR ($CDCl_3$, 360 MHz) δ 1.28-1.37 [m, containing d at δ 1.31 ($J$ = 7.0 Hz), 5 H in all), 1.47 (s, 9 H), 1.51-1.63 (m, 2 H), 1.61-1.63 (m, 3 H), 1.92-2.02 (m, 2 H), 2.41-2.62 (m, 2 H), 3.64 (q, $J$ = 7.0 Hz, 1 H), 5.32-5.48 (m, 2 H); $^{13}C$ NMR ($CDCl_3$, 100.6 MHz) δ 13.5 (q'), 17.9 (q'), 23.1 (t'), 28.9 (t'), 29.6 (q'), 32.2 (t'), 41.1 (t'), 48.8 (s'), 62.1 (d'), 125.1 (d'), 130.9 (d'), 197.1 (s'), 204.9 (s'); exact mass $m/z$ calcd for $C_{15}H_{26}O_2S$ 270.1653, found 270.1645.

**(*E*)-*N*-[3-[[Dimethyl(1,1-dimethylethyl)silyl]oxy]-4,4-dimethoxybutyl]-2-methyl-3-oxo-8-decenamide (32.1).**

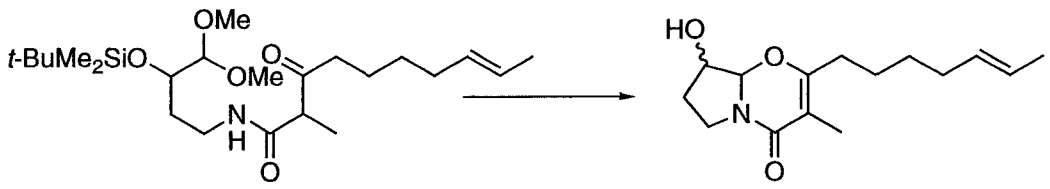


**23.6** **28.1** **32.1**

$AgOSO_2CF_3$ (224 mg, 0.864 mmol) was tipped into a stirred mixture of amine hydrochloride **23.6** (129 mg, 0.432 mmol), dry $Et_3N$ (0.12 mL, 0.864 mmol) and β-keto thioester **28.1** (116.6 mg, 0.432 mmol) in dry THF (5 mL). The reaction was over in ca 20 min (TLC control, silica, 1:1 EtOAc-hexanes). The mixture was loaded onto a dry silica gel column (2 x 18 cm) and flash chromatography, using 1:1 EtOAc-hexanes, gave **32.1** (147.4 mg, 90%) as a thick, pale yellow oil: FTIR ($CDCl_3$ cast) 3450-3150, 1720, 1643 $cm^{-1}$; $^1H$ NMR ($CDCl_3$, 400 MHz) δ 0.08 (s, 3 H), 0.09 (s, 3 H), 0.90 (s, 9 H), 1.24-1.33 (m, 2 H), 1.35 (dd, $J$ = 7.1, 0.6 Hz, 3 H), 1.52-1.61 (m, 2 H), 1.63 (d, $J$ = 4.7 Hz, 3 H), 1.67-1.83 (m, 2 H), 1.94-1.99 (m, 2 H), 2.47-2.61 (m, 2 H), 3.31-3.40 (m, 3 H), 3.43 (s, 3 H), 3.44 (d, $J$ = 1.3 Hz, 3 H), 3.72 (ddd, $J$ = 6.3, 4.9, 1.4 Hz, 1 H), 4.12 (d, $J$ = 4.8 Hz, 1 H), 5.34-5.46 (m, 2 H), 6.47 (d, $J$ = 5.5 Hz, 1 H); $^{13}C$ NMR ($CDCl_3$, 100.6 MHz) (mixture of rotamers)

δ -4.8 (q'), -4.5 (q'), 14.7 (q'), 14.8 (q'), 17.9 (q'), 18.2 (s'), 22.9 (t'), 25.9 (q'), 28.9 (t'), 31.7 (t'), 32.3 (t'), 36.1 (t'), 41.26 (t'), 41.29 (t'), 54.58 (q'), 54.64 (q'), 55.94 (d'), 56.2 (q'), 71.66 (d'), 71.71 (d'), 107.6 (d'), 125.2 (d'), 130.9 (d'), 126.29 (s'), 169.35 (s'), 209.4 (s'); exact mass *m/z* calcd for $C_{23}H_{45}NO_5Si$ 443.3067, found 443.3060.

**(*E*)-2-(5-Heptenyl)-6,7,8,8a-tetrahydro-8-hydroxy-3-methyl-4*H*-pyrrolo[2,1-b][1,3]oxazine-4-one (5.3a,b).**



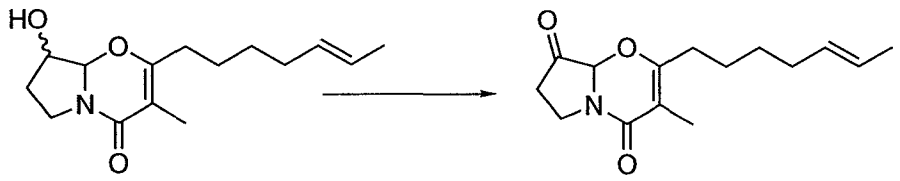
**32.1** **5.3a,b**

Aqueous $CF_3CO_2H$ (50%, 1.0 mL) was added to a stirred solution of β-keto amide **32.1** (224 mg, 0.50 mmol) in $CHCl_3$ (2 mL). Stirring was continued for 36 h, by which time the starting material had been consumed (TLC control, silica, 1:1 EtOAc-hexanes). The solvent was evaporated and the residue was left under oil pump vacuum for 24 h, to obtain a mixture of diastereoisomers **5.3** (133.5 mg, ca 100%) as a white solid. Flash chromatography over silica gel (2 x 20 cm), using 1:24 MeOH-$Et_2O$, gave the less polar diastereoisomer **5.3a** (61.4 mg, 45%) and the more polar diastereoisomer **5.3b** (56.4 mg, 42%) as colorless liquids. Compound **5.3a** had: FTIR ($CDCl_3$ cast) 3600-3100, 1643 $cm^{-1}$; $^1H$ NMR ($CDCl_3$, 400 MHz) δ 1.30-1.43 (m,

2 H), 1.48-1.60 (m, 2 H), 1.61-1.66 (m, 3 H), 1.78 (s, 3 H), 1.87-2.01 (m, 3 H), 2.15-2.33 (m, 3 H), 2.97 (br s, 1 H), 3.56-3.71 (m, 2 H), 4.42-4.46 (m, 1 H), 5.03 (d, $J$ = 3.7 Hz, 1 H), 5.35-5.47 (m, 2 H); $^{13}C$ NMR ($CDCl_3$, 100.6 MHz) δ 10.0 (q'), 17.9 (q'), 26.3 (t'), 29.1 (t'), 30.1 (t'), 30.5 (t'), 32.2 (t'), 41.8 (t'), 75.2 (d'), 92.3 (d'), 106.4 (s'), 125.2 (d'), 130.9 (d'), 163.4 (s'), 163.5 (s'); exact mass $m/z$ calcd for $C_{15}H_{23}NO_3$ 265.1678, found 265.1675.

Compound **5.3b** had: FTIR ($CDCl_3$ cast) 3600-3050, 1737, 1645 $cm^{-1}$; $^1H$ NMR ($CDCl_3$, 400 MHz) δ 1.34-1.44 (m, 2 H), 1.50-1.61 (m, 2 H), 1.65 (dd, $J$ = 4.9, 1.2 Hz, 3 H), 1.79 (s, 3 H), 1.92-2.13 (m, 4 H), 2.19-2.26 (m, 1 H), 2.30-2.38 (m, 1 H), 2.50 (br s, 1 H), 3.55-3.64 (m, 1 H), 3.66-3.78 (m, 1 H), 4.30-4.90 (m, 1 H), 5.20 (d, $J$ = 3.5 Hz, 1 H), 5.33-5.49 (m, 2 H); $^{13}C$ NMR ($CDCl_3$, 100.6 MHz) δ 10.0 (q'), 17.9 (q'), 26.3 (t'), 29.1 (t'), 29.3 (t'), 30.5 (t'), 32.2 (t'), 41.7 (t'), 70.6 (d'), 87.7 (d'), 106.8 (s'), 125.3 (d'), 130.8 (d'), 162.5 (s'), 163.1 (s'); exact mass $m/z$ calcd for $C_{15}H_{23}NO_3$ 265.1678, found 265.1670.

**(*E*)-2-(5-Heptenyl)-6,7-dihydro-3-methyl-4*H*-pyrrolo[2,1-b][1,3]oxazine-4,8(8a*H*)-dione (5.4) from less polar alcohol.**

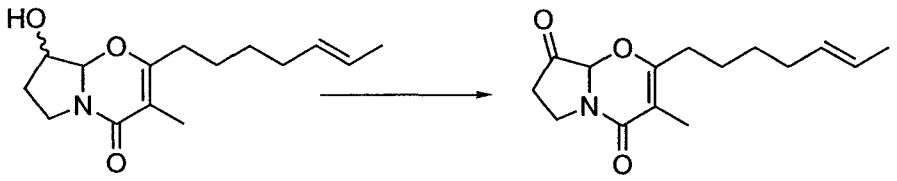


**5.3a** **5.4**

Dess-Martin periodinane (68.8 mg, 0.16 mmol) in dry $CH_2Cl_2$ (1 mL) was added to a stirred solution of the less polar alcohol **5.3a** (28.8 mg, 0.11 mmol) in dry $CH_2Cl_2$ (0.5 mL). Stirring was continued for 2 h (TLC control, silica, 3:1 EtOAc-hexanes), and the mixture was diluted with EtOAc (4 mL) and stirred for 5 min with saturated aqueous $NaHCO_3$ (2 mL) containing $Na_2S_2O_3$ (250 mg). More EtOAc (8 mL) was added, followed by water (4 mL). The aqueous layer was extracted with EtOAc, and the combined organic extracts were evaporated. Flash chromatography of the oily residue over silica gel (1 x 20 cm), using 3:1 EtOAc-hexanes, gave **5.4** (15.6 mg, 54%, or 99% after correction for recovered starting material (13.0 mg, 45%)) as a colorless liquid: FTIR ($CDCl_3$ cast) 1774, 1664 $cm^{-1}$; $^1H$ NMR ($CDCl_3$, 360 MHz) $\delta$ 1.32-1.42 (m, 2 H), 1.51-1.61 (m, 2 H), 1.64 (dd, $J$ = 3.8, 0.9 Hz, 3 H), 1.84 (s, 3 H), 1.94-2.06 (m, 2 H), 2.21-2.42 (m, 2 H), 2.62-2.83 (m, 2 H), 3.57-3.66 (m, 1 H), 4.08-4.17 (m, 1 H), 5.03 (s, 1 H), 5.32-5.48 (m, 2 H); $^{13}C$ NMR ($CDCl_3$, 50.3 MHz) $\delta$ 10.0

(q'), 17.9 (q'), 26.2 (t'), 29.1 (t'), 30.5 (t'), 32.2 (t'), 33.7 (t'), 38.0 (t'), 81.7 (d'), 107.1 (s'), 125.3 (d'), 130.8 (d'), 163.3 (s'), 163.5 (s'), 204.4 (s'); exact mass *m/z* calcd for $C_{15}H_{21}NO_3$ 263.1521, found 263.1514.

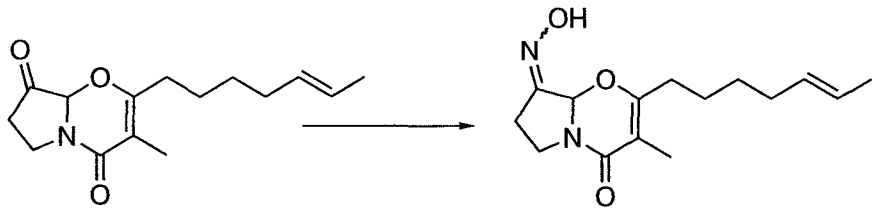
**(*E*)-2-(5-Heptenyl)-6,7-dihydro-3-methyl-4*H*-pyrrolo[2,1-b][1,3]oxazine-4,8(8a*H*)-dione (5.4) from more polar alcohol.**



**5.3b** **5.4**

*N*-Methylmorpholine *N*-oxide (12.3 mg, 0.105 mmol), $Pr_4NRuO_4$ (1.23 mg, 0.00350 mmol) and crushed 4Å molecular sieves (35.0 mg) were added in succession to a stirred solution of the more polar alcohol **5.3b** (18.6 mg, 0.07 mmol) in dry $CH_2Cl_2$ (1 mL). The mixture was stirred for 2 h and then loaded onto a silica gel column (1 x 15 cm) made up with 3:1 EtOAc-hexanes. Flash chromatography, using 3:1 EtOAc-hexanes, gave **5.4** [3.5 mg, 18% (23% after correction for recovered starting material (3.7 mg)] as a colorless liquid, spectroscopically identical to material obtained from the other isomer.

**(*E*,*E*)- and (*E*,*Z*)-2-(5-Heptenyl)-6,7-dihydro-3-methyl-4*H*-pyrrolo[2,1-b][1,3]oxazine-4,8(8a*H*)-dione 8-oxime (1) and (36).**



**5.4** **32.2, 2.1**

A solution of $H_2NOH.HCl$ (29.9 mg, 0.43 mmol) and AcONa (60.8 mg, 0.44 mmol) in water (0.25 mL) was added to ketone **5.4** (22.6 mg, 0.09 mmol). EtOH (0.25 mL) was added to the mixture until turbidity disappeared, and the mixture was stirred for 3 h, by which time the starting material had been consumed (TLC control, silica, 3:1 EtOAc-hexanes). The solvent was evaporated and the residue was washed through a silica pad (1 x 4 cm), using EtOAc (15 mL). Evaporation of the filtrate gave a mixture of oxime isomers (23.8 mg, 99%) as a pale yellow solid. Flash chromatography over silica gel (1 x 20 cm), using 3:1 EtOAc-hexanes, gave the less polar *E*-isomer **2.1** (17.9 mg, 74%) and the *Z* isomer **32.2** (4.9 mg, 20%) as white solids. The $^1H$ NMR ($CDCl_3$, 400 MHz) and $^{13}C$ NMR ($CDCl_3$, 100.6 MHz) spectra of **2.1** were the same as those reported; the compound had: mp 146-149 °C.

Compound **32.2** (*Z* isomer) had: mp 138.5-140 °C; FTIR ($CH_2Cl_2$ cast) 3600-3050, 1641 $cm^{-1}$; $^1H$ NMR ($CD_2Cl_2$, 400 MHz) δ 1.35-1.44 (m, 2 H), 1.55-1.60 (m, 2 H), 1.63 (d, $J$ = 3.6 Hz,

3 H), 1.78 (s, 3 H), 1.96-2.02 (m, 2 H), 2.17-2.25 (m, 1 H), 2.32-2.39 (m, 1 H), 2.63-2.70 (m Hz, 1 H), 2.79-2.90 (m, 2 H), 3.26-3.36 (m, 1 H), 3.98-4.07 (m, 1 H), 5.38-5.45 (m, 2 H), 5.81 (d, $J$ = 1.3 Hz, 1 H), 7.66 (s, 1 H); $^{13}C$ NMR ($CDCl_3$, 100.6 MHz) $\delta$ 10.1 (q'), 17.9 (q'), 26.3 (t'), 27.1 (t'), 29.0 (t'), 30.5 (t'), 32.2 (t'), 41.4 (t'), 79.8 (d'), 106.9 (s'), 125.2 (d'), 130.9 (d'), 156.9 (s'), 163.2 (s'), 164.0 (s') (the spectrum showed a trace of the *E* isomer **2.1**); exact mass *m/z* calcd for $C_{15}H_{22}N_2O_3$ 278.1631, found 278.1624.

A sample (4.9 mg) of the *Z* oxime **32.2** was stored for 51 h in $CDCl_3$. Evaporation of the solvent and flash chromatography of the residue over silica gel, using 3:1 EtOAc-hexanes, gave **2.1** (2.2 mg, 44%) and **32.2** (2.1 mg, 42%).

The following Tables show the NMR data for the natural and synthetic brevioxime.

**Table 1 ($^1$H NMR spectrum of brevioxime)**

| Natural | Natural | Synthetic | Synthetic |
|---|---|---|---|
| $CDCl_3$, 300 MHz | | $CDCl_3$, 400 MHz | |
| 1.35 | m, 2 H | 1.35-1.43 | m, 2 H |
| 1.55 | m, 2 H | 1.50-1.62 | m, 2 H |
| 1.63 | d, $J$ = 2.4 Hz, 3 H | 1.63 | d, $J$ = 2.3 Hz, 3 H |
| 1.83 | s, 3 H | 1.83 | s, 3 H |
| 1.98 | m, 2 H | 1.94-2.04 | m, 2 H |
| 2.28 | m, 2 H | 2.20-2.40 | m, 2 H |
| 2.88 | m, 2 H | 2.78-2.99 | m, 2 H |
| 3.47 | m, 1 H | 3.44-3.53 | m, 1 H |
| 4.05 | m, 1 H | 4.02-4.13 | m, 1 H |
| 5.38 | m, 2 H | 5.33-5.49 | m, 2 H |
| 5.50 | s, 1 H | 5.56 | s, 1 H |
| 8.02 | s, 1 H | 7.95 | s, 1 H |

**Table 2 ($^{13}C$ NMR spectrum of brevioxime)**

| **Natural** | **Synthetic** |
|---|---|
| $CDCl_3$, 75 MHz | $CDCl_3$, 100 MHz |
| 10.0 | 10.1 |
| 17.8 | 18.0 |
| 23.6 | 23.8 |
| 26.2 | 26.4 |
| 29.1 | 29.3 |
| 30.5 | 30.7 |
| 32.1 | 32.3 |

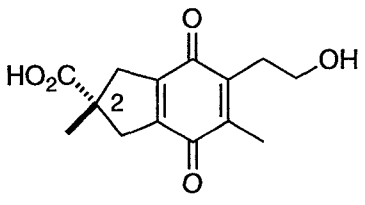
# CHAPTER 2

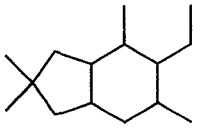
## SYNTHESIS OF (±)-PURAQUINONIC ACID

### Introduction

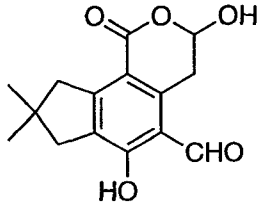
Puraquinonic acid (**1.1**) is a fungal metabolite produced by cultures of *Mycena pura*.[1] The compound, which is optically active, with $[\alpha]_D^{22}$ +1, induces differentiation of HL-60 cells (human promyelocytic leukemia). This is an important property since there is evidence[2] that induction of cell differentiation leads to suppression of cell proliferation. Puraquinonic acid, may therefore serve as a lead compound in the design of drugs to treat leukemia.



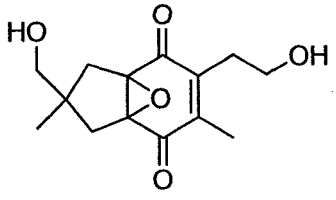
**1.1**



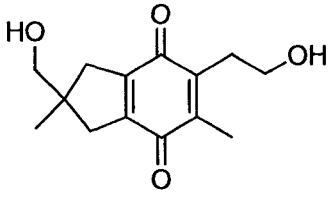
**1.2**



**1.3**



**1.4**



**1.5**

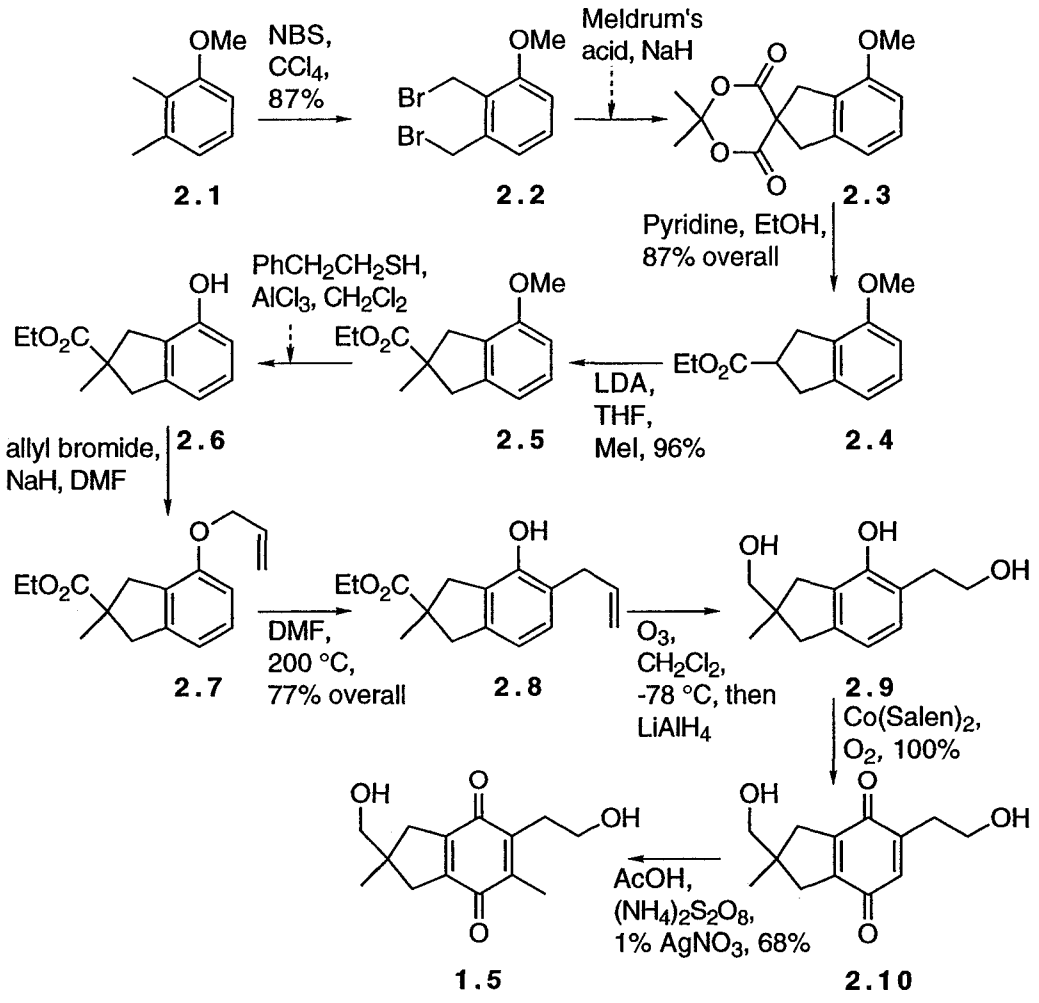
**Scheme 1**

Puraquinonic acid is a norilludalane sesquiterpene, illudalanes being natural products with the skeleton **1.2**,

such as illudalic acid (**1.3**).[3] Two compounds, **1.4** (2,9-epoxydeliquinone) and **1.5** (deliquinone), closely related to puraquinonic acid have also been isolated,[4] but their biological properties do not appear to have been examined.

## Synthesis of (±)-deliquinone

Prior to our own publications no synthetic work on puraquinonic acid or its relatives (**1.4** and **1.5**) had been reported, but recently, Kraus and Choudhury described[5] a short synthesis of (±)-deliquinone. 2,3-Dimethylanisole



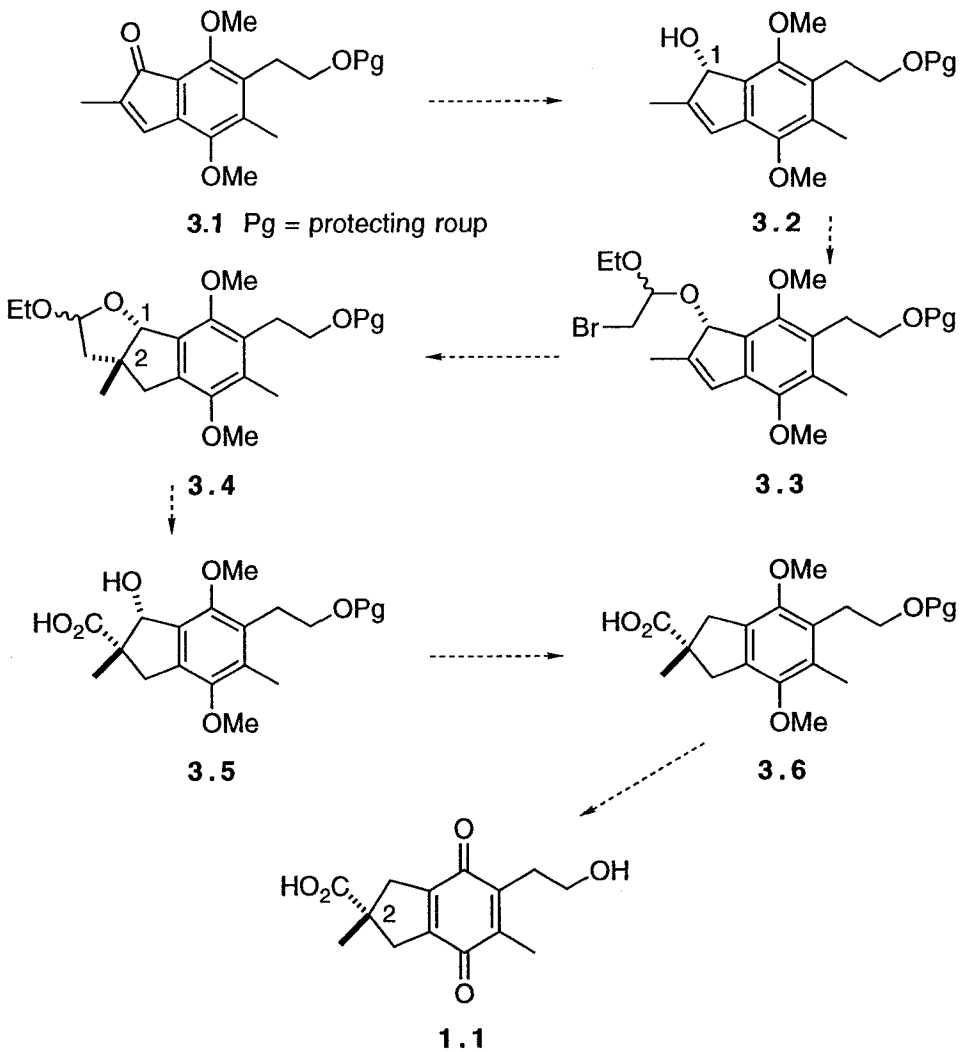
**Scheme 2**

(**2.1**) was subjected to double benzylic bromination, and then reaction with the sodium salt of Meldrum's acid afforded the spiro compound **2.3**. Next, treatment with EtOH and pyridine gave the ethyl ester **2.4**, which was then methylated. Removal of the *O*-methyl group and *O*-allylation now set the stage for a Claisen rearrangement, which afforded phenol **2.8**. Ozonolytic double bond cleavage and hydride reduction of the ozonide produced the phenolic alcohol **2.9**. This was oxidized to the corresponding quinone (**2.10**) and, finally, addition of a methyl radical under oxidative conditions introduced the last carbon required, giving (±)-deliquinone **1.5**.

**Previous exploratory studies on the synthesis of (±)-puraquinonic acid done in this laboratory**

Extensive exploratory work had been done in this laboratory by M. Sannigrahi[6] on the synthesis of puraquinonic acid (**1.1**), and, eventually, a promising route emerged.

The approach was based on the radical cyclization of a Stork bromoacetal (Scheme 3, **3.3** → **3.4**). According to the rules for ring closure[7] a *cis*-fused product must form, so that the stereochemistry at C(1) in **3.2** would control the stereochemistry at C(2) in **3.4**. It was planned to degrade the heterocyclic ring in **3.4** (**3.4** → **3.5**) and then to remove the remaining hydroxyl by Barton deoxygenation (**3.5** → **3.6**). Removal of the remaining protecting group and oxidation of the benzene ring would then afford puraquinonic acid (**1.1**). The starting alcohol (**3.2**) was expected to be available from

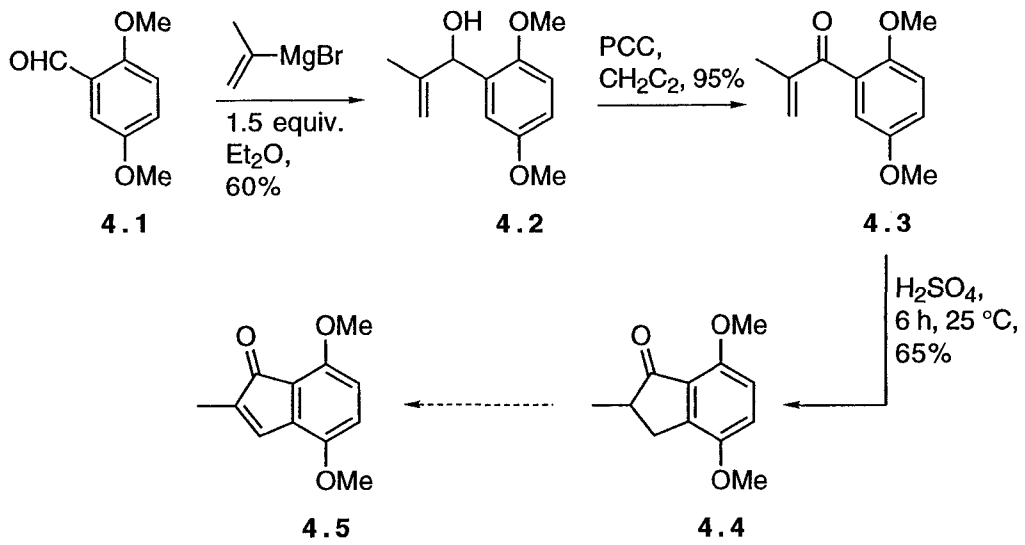


**Scheme 3**

the corresponding ketone (**3.1**) by use of one of the many methods for asymmetric ketone reduction.[8]

In order to implement the plan summarized in Scheme 3, the first task was to prepare indenone **3.1**. Several approaches were investigated.[6] One of these was based on a Nazarov cyclization,[9] and it was this route that was eventually used for the work described in this Thesis. Sannigrahi developed this approach first in a simple model

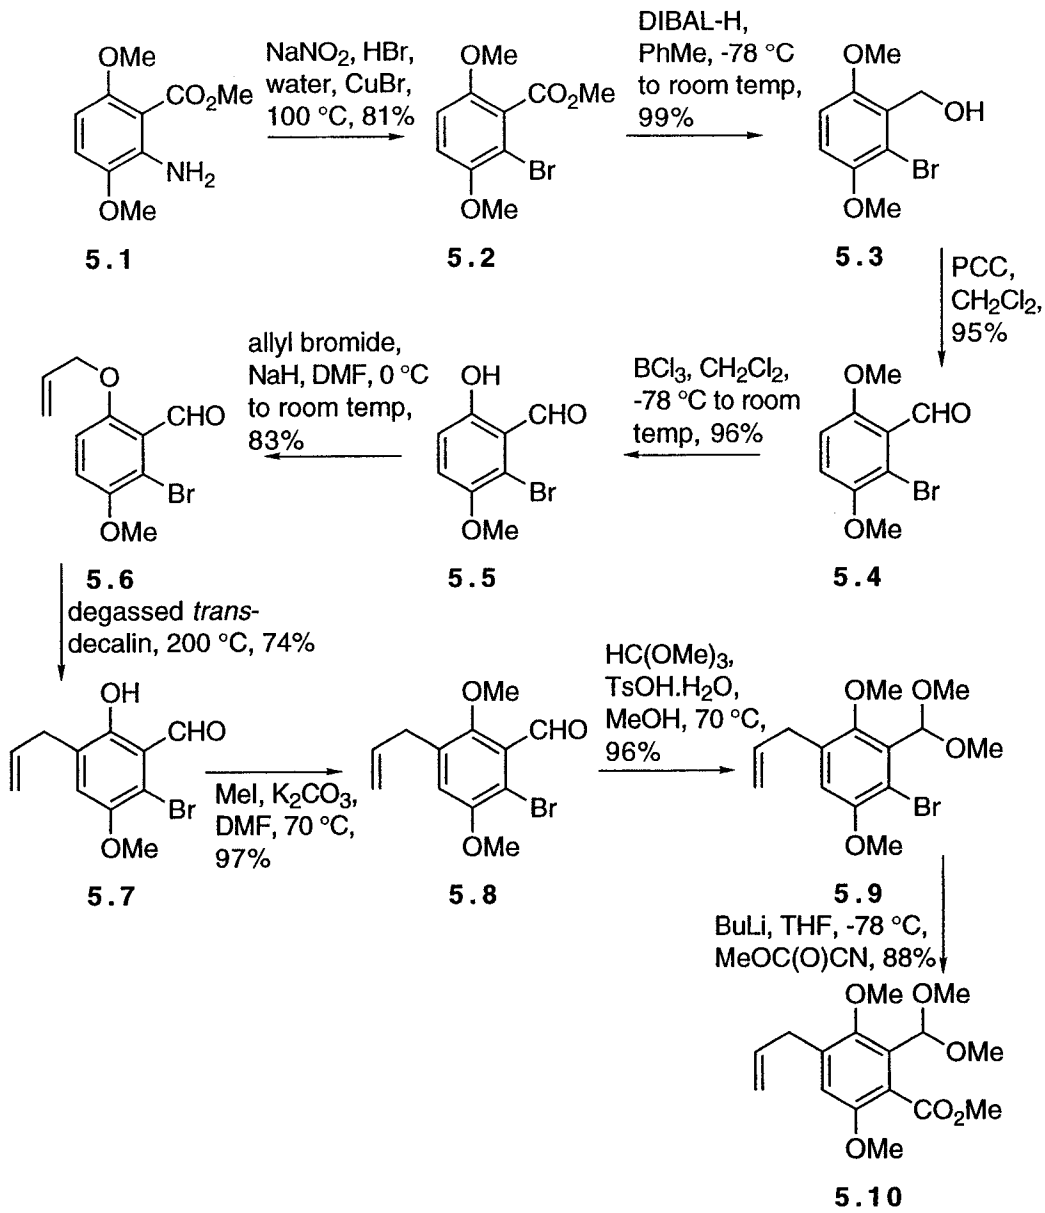
system (Scheme 4). Aldehyde **4.1** was treated with isopropenylmagnesium bromide, and the resulting alcohol was oxidized to ketone **4.3**. When this was stored in concentrated $H_2SO_4$ for 6 h, it was converted by Nazarov cyclization[9] into



**Scheme 4**

indanone **4.4**. As this was a model sequence, no attempt was made to desaturate the indanone (**4.4** → **4.5**); this should, in any case, be a very simple operation. With a method for making the five-membered ring available, attention was turned to the preparation of an aldehyde corresponding to **4.1**, but carrying suitable substituents for elaboration into the methyl and hydroxyethyl groups of puraquinonic acid. To this end, the ester **5.1**[10] was elaborated as shown in Schemes 5 and 6. These reactions represent a refined version of several related sequences studied by Sannigrahi.

A classical Sandmeyer reaction[11] served to convert **5.1** into the bromide **5.2**, and this, in turn, was converted into

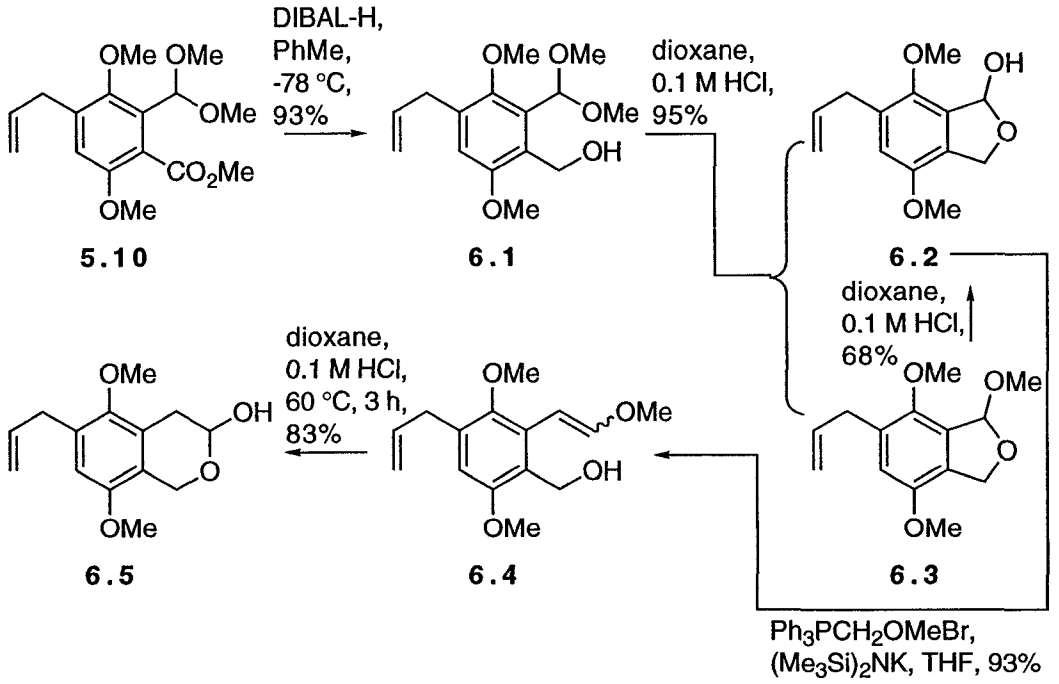


**Scheme 5**

aldehyde **5.4** by reduction to the alcohol (**5.2** → **5.3**) and oxidation.[12] Regioselective demethylation, directed by the aldehyde group (**5.4** → **5.5**),[13] allylation (**5.5** → **5.6**),[14] and thermal Claisen rearrangement (**5.6** → **5.7**) then gave phenol **5.7**. This was methylated in the standard way, and protected as its dimethyl acetal **5.9**. The use of a *dimethyl* instead of

a *cyclic* acetal and the indicated order of the last four steps – allylation, rearrangement, *O*-methylation and acetalization – was the best of several possibilities that were examined. At this point, halogen-metal exchange, and treatment with Mander's reagent[15] gave ester **5.10**. Since the ester is destined to provide the methyl substituent of puraquinonic acid, it would seem more logical to quench the anion derived from **5.9** with MeI rather than with Mander's reagent, but this approach eventually incurred complications, as described below (see discussion associated with Scheme 12).

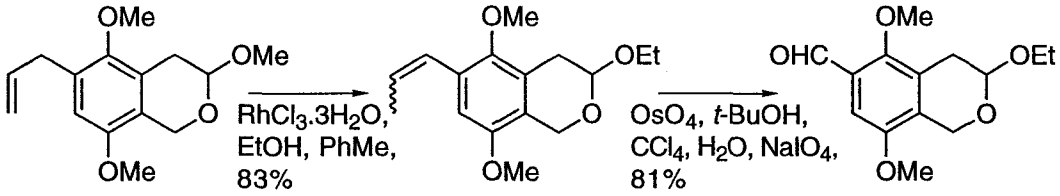
The acetal and ester groups were next modified, as shown in Scheme 6. Ester reduction gave alcohol **6.1**, and acid hydrolysis then afforded a mixture of lactol **6.2** and the



**Scheme 6**

corresponding lactol methyl ether **6.3**. The latter could be hydrolyzed to the lactol by further treatment with acid. The second carbon of the eventual hydroxyethyl side chain of puraquinonic acid was then introduced by Wittig olefination[16] of the lactol to obtain a mixture of *Z* and *E* enol ethers **6.4**. Mild acidic hydrolysis then gave lactol **6.5** (83%) together with a small amount of the corresponding lactol methyl ether.

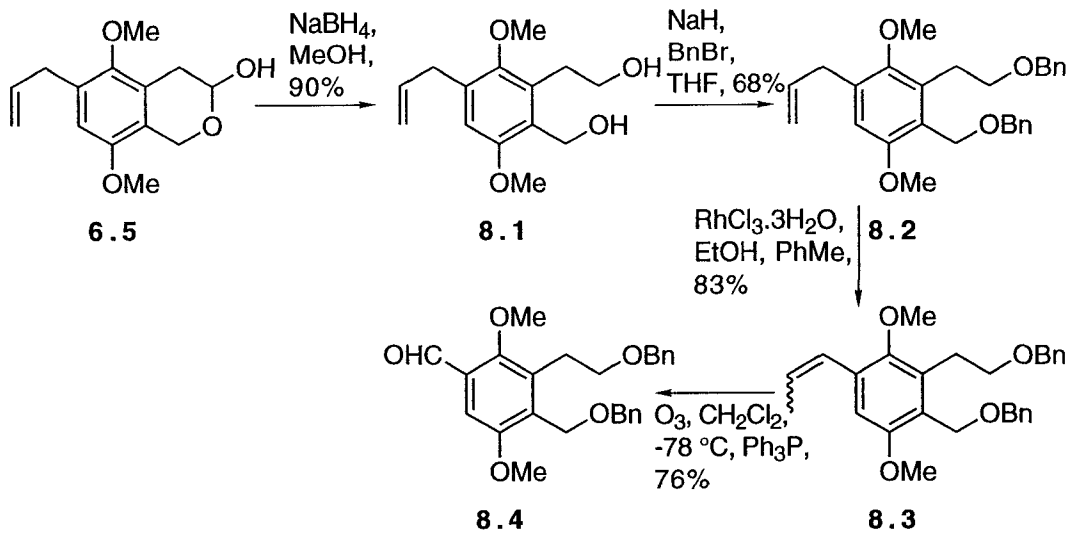
Lactol **6.5** and its methyl ether were elaborated in several ways. In the first series of reactions the lactol methyl ether **7.1** (obtained in early experiments as a byproduct in the formation of **6.5**) was treated with $RhCl_3.3H_2O$[17] in order to shift the pendant double bond into conjugation with the aromatic ring (Scheme 7), and the double bond was then cleaved, using the classical $OsO_4$-$NaIO_4$ combination. During the double bond isomerization alkoxy exchange occurred so that the product (**7.2**) was a lactol ethyl ether.



**7.1** **7.2** **7.3**

**Scheme 7**

In the second series of experiments (Scheme 8), lactol **6.5** was reduced to diol **8.1**, and the hydroxyls were protected by benzylation. The pendant double bond was moved,



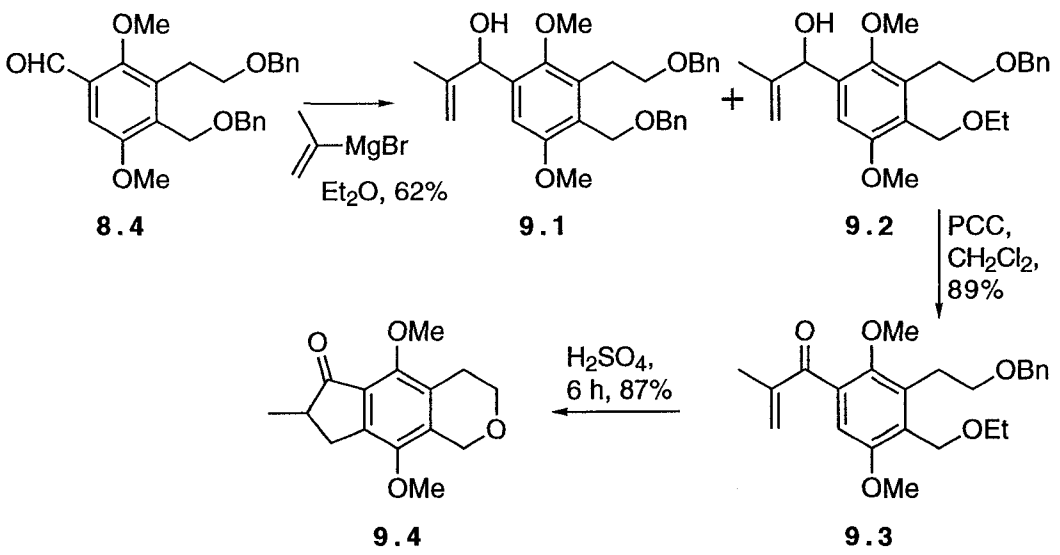
**Scheme 8**

as before,[17] and then cleaved by ozonolysis.

Aldehyde **8.4** served as the key intermediate in a method for building the five-membered ring. Condensation with isopropenylmagnesium bromide gave alcohols **9.1** and **9.2** (Scheme 9). The fact that one of the benzyl groups had been replaced by an ethoxy group made no difference to the overall scheme. Oxidation of **9.2** set the stage for a Nazarov cyclization[9] (**9.3** → **9.4**), which was accomplished in 87% yield by storing **9.3** in concentrated $H_2SO_4$ for 6 h. During the Nazarov cyclization the two protected side chains were incorporated into a ring, but it was felt – in the event, correctly (see later) – that this structural feature could be modified so as to generate the required methyl and hydroxyethyl substituents.

The experiments summarized in Scheme 9 represent the most advanced stages of Sannigrahi's work, and I took over at

that point.



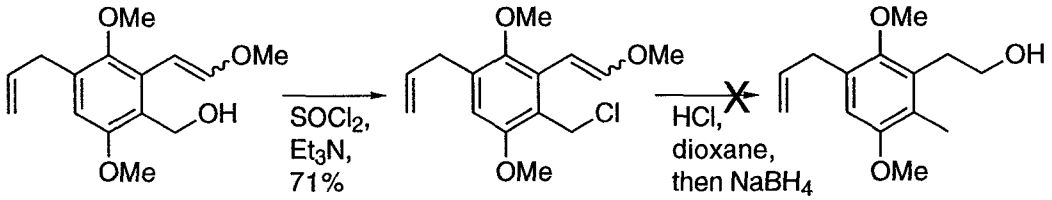
**8.4** **9.1** **9.2** **9.4** **9.3**

**Scheme 9**

## DISCUSSION OF RESEARCH RESULTS

### Synthesis of (±)-puraquinonic acid

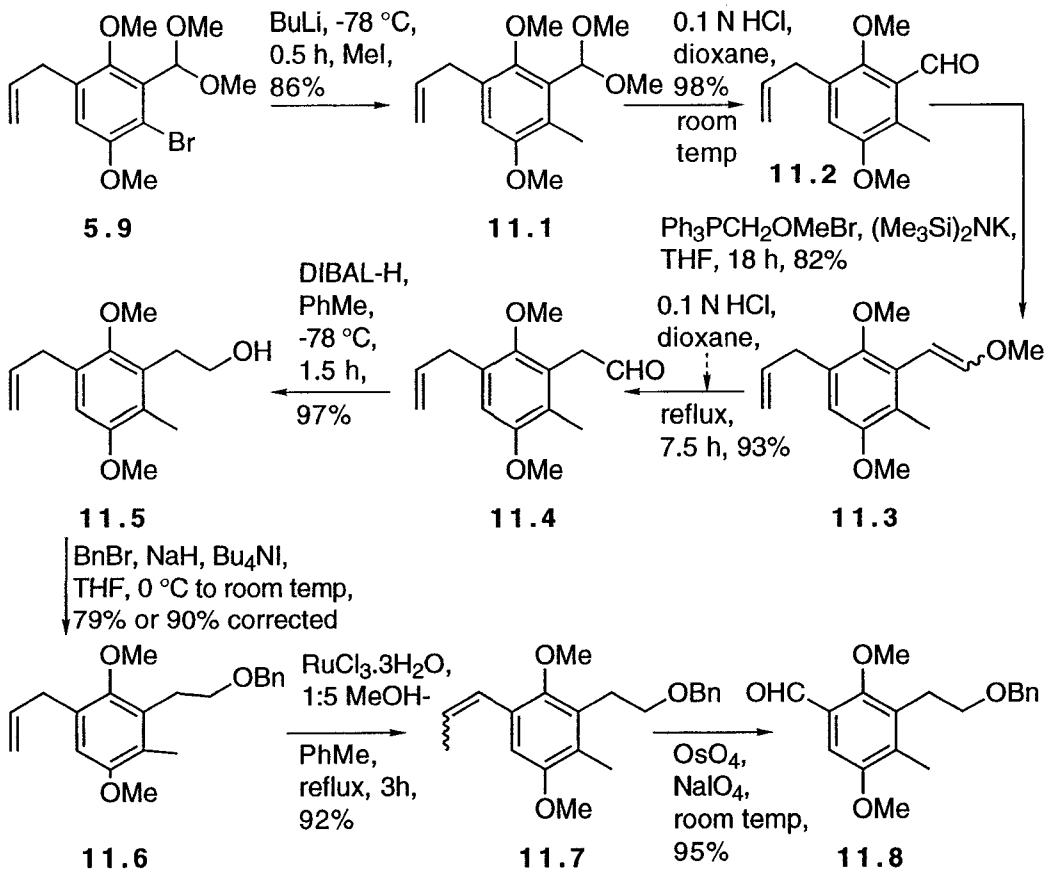
We first decided to introduce the aromatic methyl substituent of puraquinonic acid at an early stage. To this end, the enol ethers **6.4** were converted (Scheme 10) into the corresponding benzylic chlorides **10.1**, in the expectation that acid hydrolysis (to release an aldehyde group), and treatment with $NaBH_4$ would serve to generate **10.2**. However, the hydrolysis-reduction step that ought to have yielded **10.2**, gave, instead, a complex mixture. We turned, therefore, to an earlier intermediate (**5.9**).



**6.4** **10.1** **10.2**

**Scheme 10**

Halogen-metal exchange and reaction with MeI, followed by acid hydrolysis (Scheme 11, **5.9** → **11.1** → **11.2**) proceeded without incident, and the aldehyde group was then subjected to Wittig olefination, as before (cf. Scheme 6). Acid hydrolysis released an aldehyde group (Scheme 11, **11.3** → **11.4**). Reduction with DIBAL-H and benzylation – all under standard conditions – took the route as far as **11.6**. The double bond was then isomerized[17] and cleaved (**11.6** → **11.7**

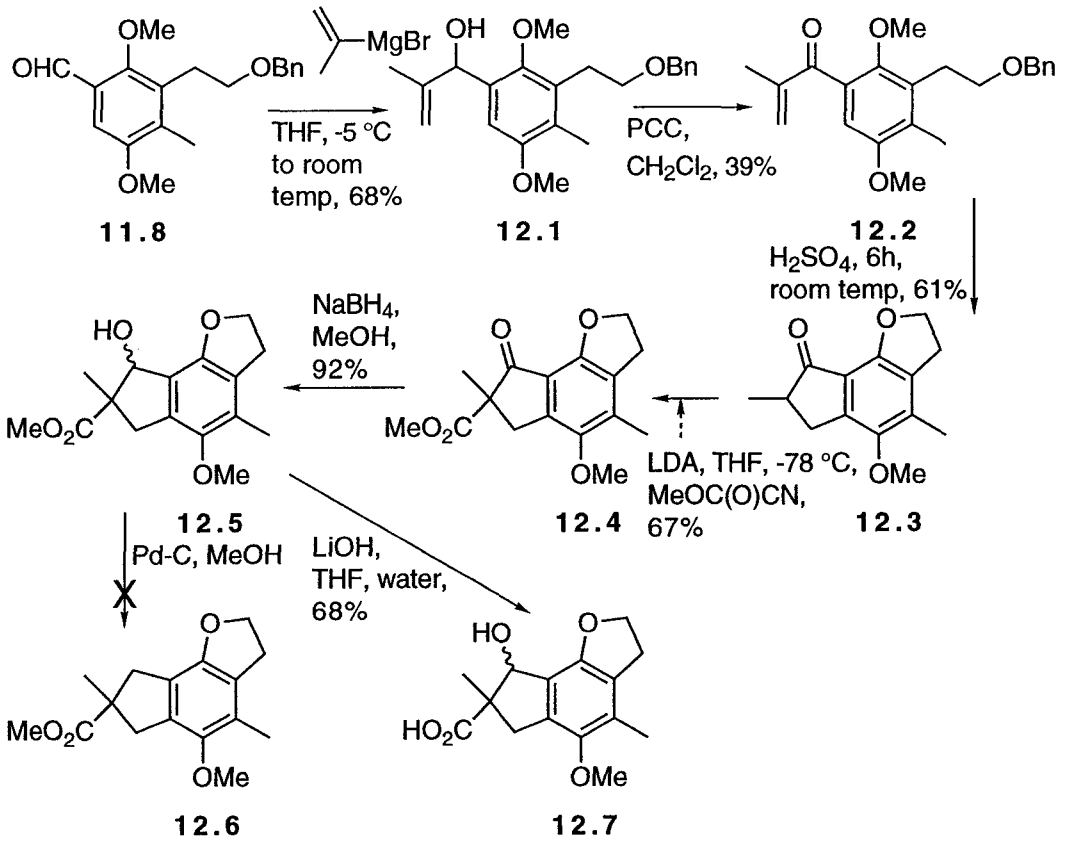


**Scheme 11**

→ **11.8**), bringing us to the point where assembly of the five-membered ring could be started.

Aldehyde **11.8** reacted (Scheme 12) with isopropenyl-magnesium bromide to give **12.1** (68%) and a very small amount (2% yield) of the corresponding phenol in which the methoxy group adjacent to the hydroxyl had been demethylated. PCC oxidation of **12.1** led to ketone **12.2**, and this was stored in concentrated $H_2SO_4$ to effect Nazarov cyclization.[9] The five-membered ring did indeed form, but at the same time the oxygenated side chain and adjacent methoxy group were unexpectedly converted into a heterocycle (**12.2** → **12.3**).

At the time, this was not regarded as significant, as we felt that compound **12.3** could be accommodated into our plans without any additional steps.

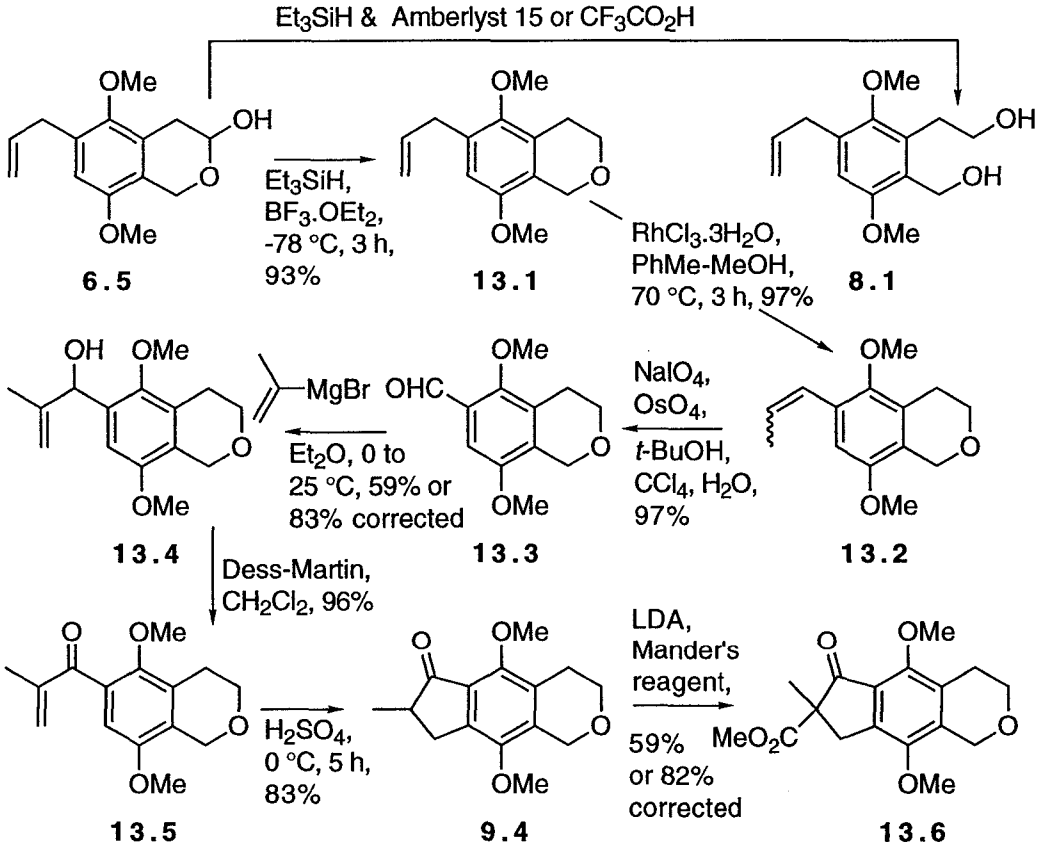


**Scheme 12**

Acylation of **12.3** with Mander's reagent[15] produced (67%) the desired β-keto ester **12.4**, and we proceeded to try to remove the unwanted ketone oxygen by reduction ($NaBH_4$, MeOH, 92%) and hydrogenolysis. Surprisingly, the hydrogenolysis step (**12.5** → **12.6**) did not work. Hydrolysis of **12.5** gave the acid **12.7**. When we treated **12.7** with $BBr_3$ an unidentified brown solid was obtained, and we could not detect ($^1H$ NMR) any product in which the heterocyclic ring

had been opened. In retrospect, we realize that we should have tried $(NH_4)_2Ce(NO_3)_6$ in the presence of 2,6-pyridinedicarboxylic acid *N*-oxide (see later) in order to open the heterocycle.[18]

Because of our failure to open the five-membered heterocyclic ring of the dihydrobenzofuran **12.7**, we decided to return to the isochroman series. Formation of isochroman **9.4** had been unexpected, but we realized that we might benefit from the process, because it represents a method for protection of the hydroxyethyl side chain. In fact, formation of the heterocyclic ring in **9.4** turned out to be a key factor in the success of our approach to puraquinonic



**Scheme 13**

acid.

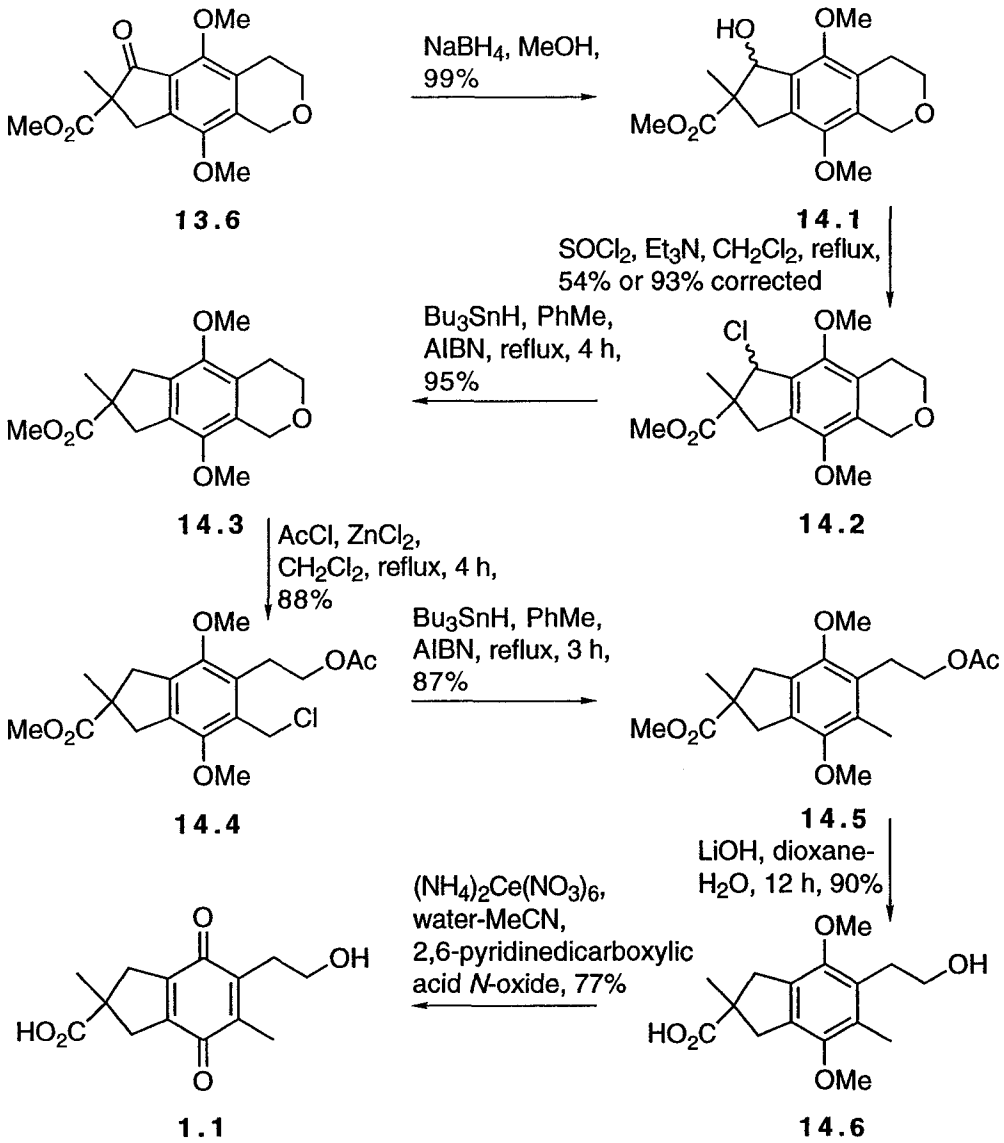
We decided to generate the isochroman at an earlier stage, and to this end, lactol **6.5** was elaborated as shown in Scheme 13.

Treatment of **6.5** with $Et_3SiH$ in the presence of *freshly* distilled $BF_3.OEt_2$ gave **13.1**.[19] A very high yield (93%) was obtained, but only if freshly distilled $BF_3.OEt_2$ was used. Use of $Et_3SiH$ together with Amberlyst 15 gave mainly diol **8.1**, which was inert to further treatment with Amberlyst 15 or $CF_3CO_2H$. When diol **8.1** was treated with $Et_3SiH$ and $CF_3CO_2H$ the hydroxymethyl group was not converted into a methyl group.

The next steps followed the sequence established in earlier work. Migration of the pendant double bond,[17] and oxidative double bond cleavage (**13.1** → **13.2** → **13.3**) set the stage for elaboration of the five-membered ring. Reaction with isopropenylmagnesium bromide – an excess must be avoided, in order to suppress *O*-demethylation – and Dess-Martin oxidation gave the substrate (**13.5**) required for the Nazarov cyclization. This occurred without incident; in particular, the presence of the oxygen heterocycle precluded unwanted involvement of one of the methoxy groups. The Nazarov cyclization product (**9.4**) was then acylated with Mander's reagent. All the steps of Scheme 13 worked well, although in two cases correction had to be made for recovered starting material.

At this point, it was necessary to deoxygenate the

ketone and open the heterocyclic ring. We had planned to effect both steps by sequential hydride reduction and hydrogenolysis, there being some precedent[20] for opening the oxygen heterocycle. However, this approach was unsuccessful,



**Scheme 14**

and the tasks were accomplished as follows. Reduction of ketone **13.6** with $NaBH_4$ gave alcohols **14.1**, and these were

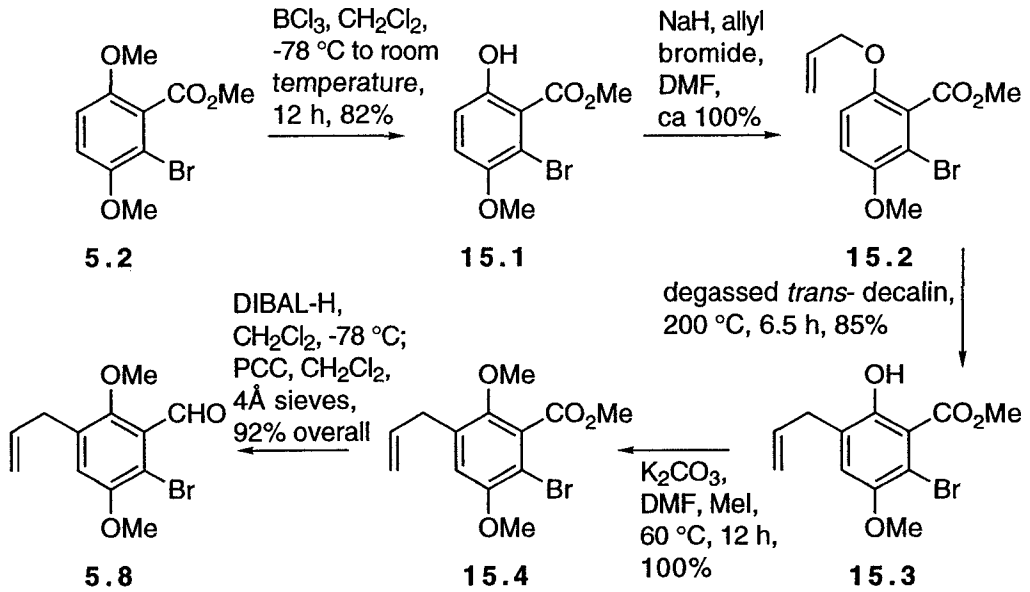
treated with $SOCl_2$ in order to replace the OH by Cl (Scheme 14, **13.6** → **14.1** → **14.2**). Stannane reduction then completed the deoxygenation process.

Next, the heterocycle was opened by a method[21] that involves heating with AcCl in the presence of $ZnCl_2$. This operation generated the acetoxy chloride **14.4**, from which the halogen was removed by stannane reduction (**14.3** → **14.4** → **14.5**). Base hydrolysis with LiOH removed the acetyl group and hydrolyzed the methyl ester, releasing hydroxy acid **14.6**. Finally, oxidation with $(NH_4)_2Ce(NO_3)_6$ in the presence of 2,6-pyridinedicarboxylic acid *N*-oxide[18] generated the quinone system, giving (±)-puraquinonic acid in 77% yield.[22]

Generation of the quinone as just described was the result of several exploratory experiments. Initially, we had treated **14.5** with $(NH_4)_2Ce(NO_3)_6$ but recovered the dimethoxy compound unchanged. Examination of the literature revealed the beneficial effects of adding 2,6-pyridinedicarboxylic acid *N*-oxide,[18] and **14.5** was then converted into the corresponding quinone (77%) by using the additive. However, attempts to hydrolyze the acetate and methyl ester groups of the resulting quinone resulted in destruction of our compound. For this reason, the hydrolysis was done before treatment with $(NH_4)_2Ce(NO_3)_6$.

During the course of our experiments we used up the supply of starting material (**5.10**) left by Sannigrahi and, in preparing more of its precursor **5.8**, we followed a slightly different route (see Scheme 15) from the one she had used.

Ester **5.2** was selectively demethylated with $BCl_3$ – use of $BBr_3$ had been found by Sannigrahi to cause extensive demethylation of both ether groups – and the resulting phenol **15.1** was allylated in the usual way. Thermal Claisen rearrangement and remethylation gave ester **15.4**, which was reduced down to the alcohol level, and reoxidized to aldehyde **5.8**. This route is one step shorter than the previous method, but was not used routinely since the first run provided sufficient material to complete our work. (As we did not repeat the sequence to obtain good spectral data, we have not included the details in the Experimental Section; our sample of **5.8** was identical to the previous samples.)



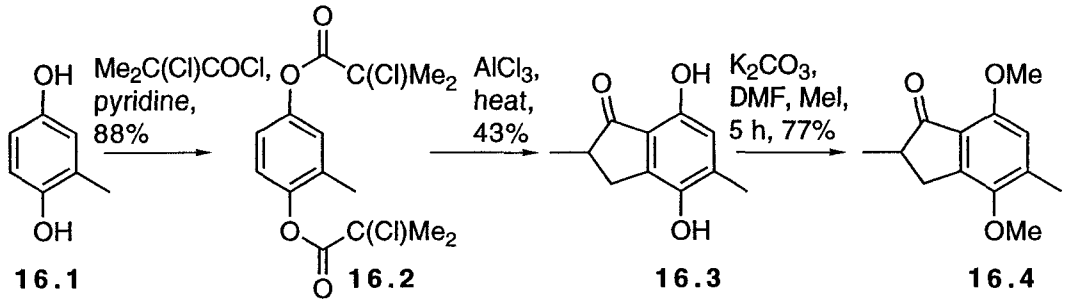
**Scheme 15**

## Second route to (±)-puraquinonic acid

Having completed the above synthesis, we embarked on a shorter route that also bypasses the requirement that the

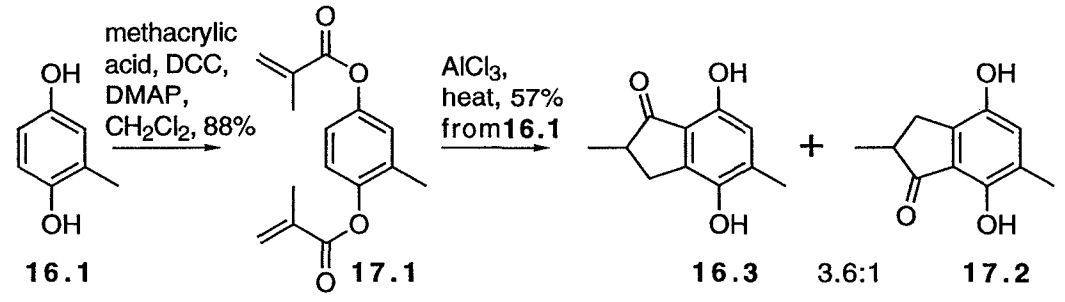
hydroxyethyl side chain be protected in such a way that it cannot close onto the oxygen of the adjacent methoxy group during the Nazarov cyclization.

The bisphenol **16.1** was acylated with $Me_2C(Cl)COCl$ and the product (**16.2**) was treated with $AlCl_3$, first at room temperature, and then at 190 °C, both steps being taken from the patent literature.[23] No yield is given in the patent for the first step, but, not surprisingly, it worked well (88%).



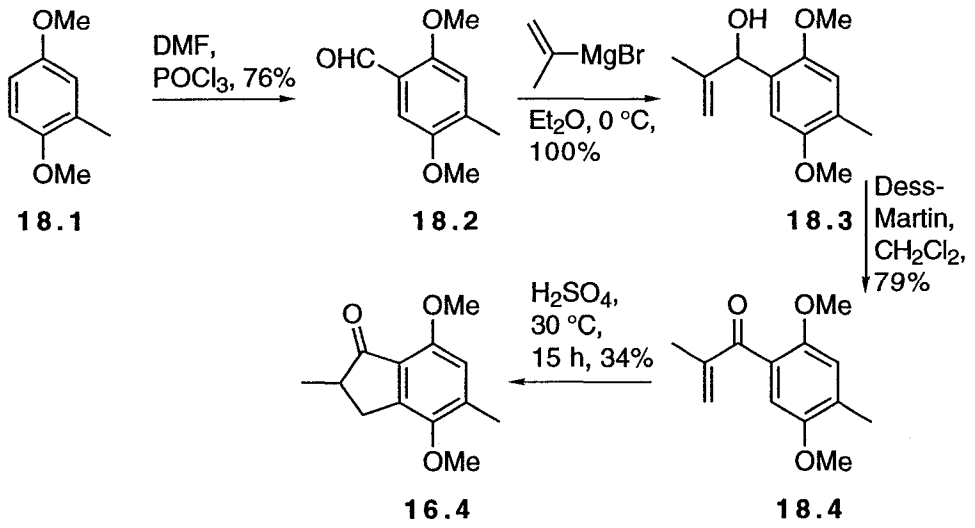
**Scheme 16**

The $AlCl_3$-induced Fries rearrangement and Nazarov cyclization (**16.2** → **16.3**) (for which, again, no yield is given) afforded the indanone **16.3** in 43% yield. Although not efficient, the reaction is easy to do and gram quantities of **16.3** and **16.4** are readily available.



**Scheme 17**

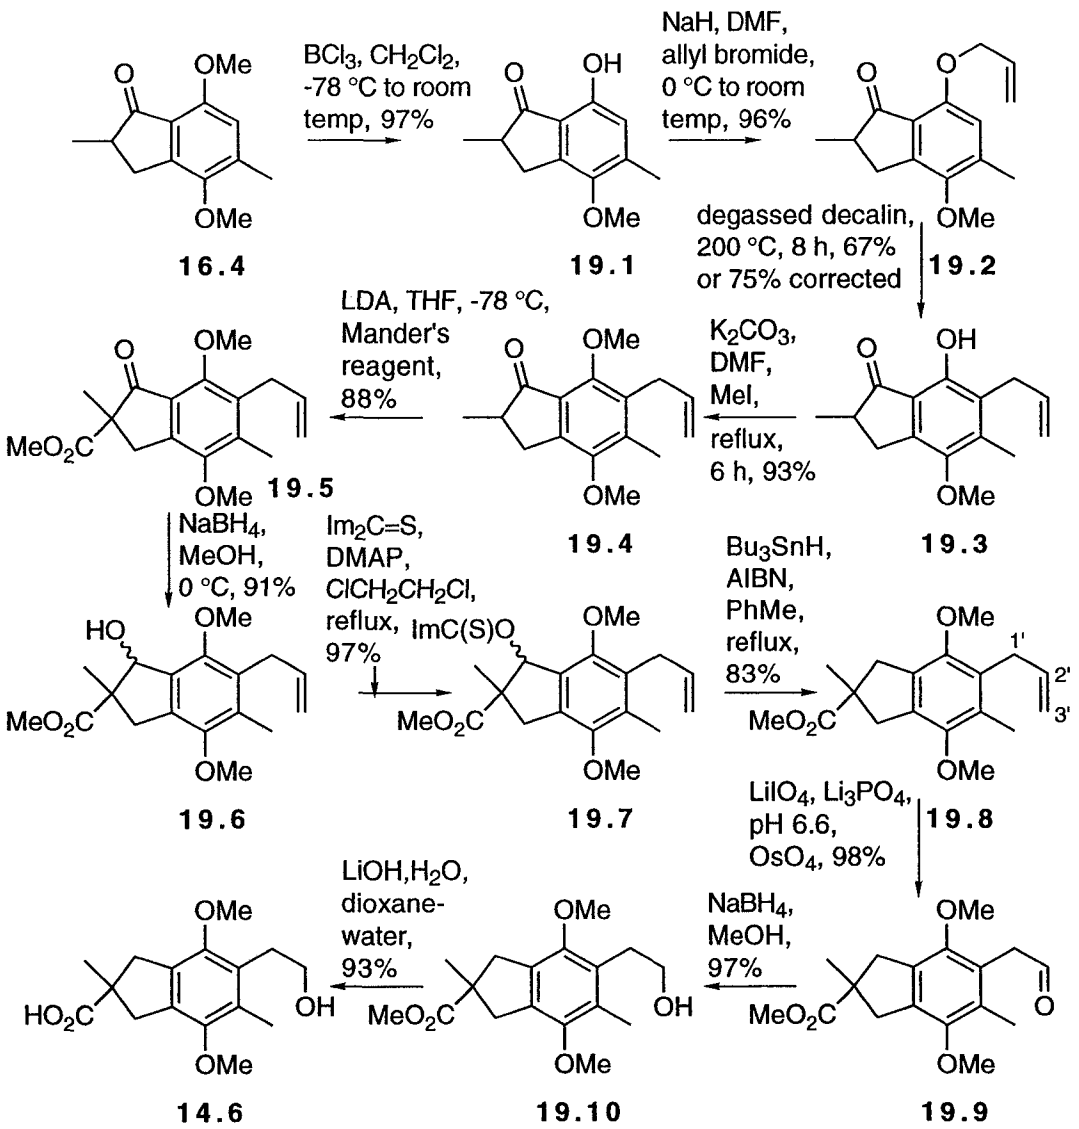
An alternative route was also examined, in which the need to prepare $Me_2C(Cl)COCl$ is avoided and commercial methacrylic acid is used instead, as shown in Scheme 17. Methylation of the mixture of **16.3** and **17.2** allowed easy separation of the isomers and afforded the bis-methyl ether **16.4**. This substance was also prepared in yet a different way (Scheme 18).



**Scheme 18**

Formylation[24] of the commercially available bis-ether **18.1** gave **18.2** in 76% yield. Reaction with isopropenyl-magnesium bromide and Dess-Martin oxidation[25] both worked well (100% and 79%, respectively) but, when the resulting enone (**18.4**) was subjected to our standard conditions for Nazarov cyclization, the desired product was formed in poor yield (34%). Use of $Me_3SiOSO_2CF_3$ destroyed the starting material (**18.4**) without giving any of the required product; **18.4** was inert to $TiCl_4$. Consequently, this route was abandoned.

With **16.4** in hand, we proceeded as summarized in Scheme 19.



**Scheme 19**

Selective demethylation of **16.4**, directed by the carbonyl group, was achieved on treatment with $BCl_3$ (-78 °C to room temperature, 97%).[13a] From that point, *O*-allylation (**19.1** → **19.2**, 96% or 99% after correction for recovered **19.1**), Claisen rearrangement (**19.2** → **19.3**, 200 °C, 8 h,

67%, or 75% after correction for recovered **19.2**), and *O*-methylation (93%) gave the highly substituted indanone derivative **19.4**. Acylation with Mander's reagent [LDA, MeOC(O)CN, 88%] then provided keto ester **19.5**, which contains all the required skeletal carbons and the appropriate functionality for conversion into puraquinonic acid.

An attempt to remove the ketonic oxygen by Wolff-Kishner reduction was not successful, the ketone being destroyed. Reduction of the ketone carbonyl ($NaBH_4$, MeOH, 91%) gave alcohols **19.6**, which could be converted ($SOCl_2$, $Et_3N$) in low yield (23%) into the corresponding unstable chlorides (not shown in Scheme 19). However, radical deoxygenation by the Barton method (**19.6** → **19.7** → **19.8**, 80% overall) took the route to a stage where the 2',3' double bond had to be cleaved. This seemingly straightforward operation was initially troublesome, as ozonolysis resulted in destruction of the starting material, and treatment with $OsO_4$-$NaIO_4$ under standard conditions[26] gave the required aldehyde **19.9** only in low yield (ca 22%). However, use of $OsO_4$-$LiIO_4$ in an aqueous phosphate buffer at pH 6.6[27] afforded **19.9** in 98% yield, and $NaBH_4$ reduction (97%) led to alcohol **19.10**. Simple hydrolysis (LiOH, aqueous THF, 93%) liberated the parent acid **14.6**,[22,28] which we had previously[22] oxidized [$(NH_4)_2Ce(NO_3)_6$, 2,6-pyridinedicarboxylic acid *N*-oxide,[18] 77%] to racemic puraquinonic acid.

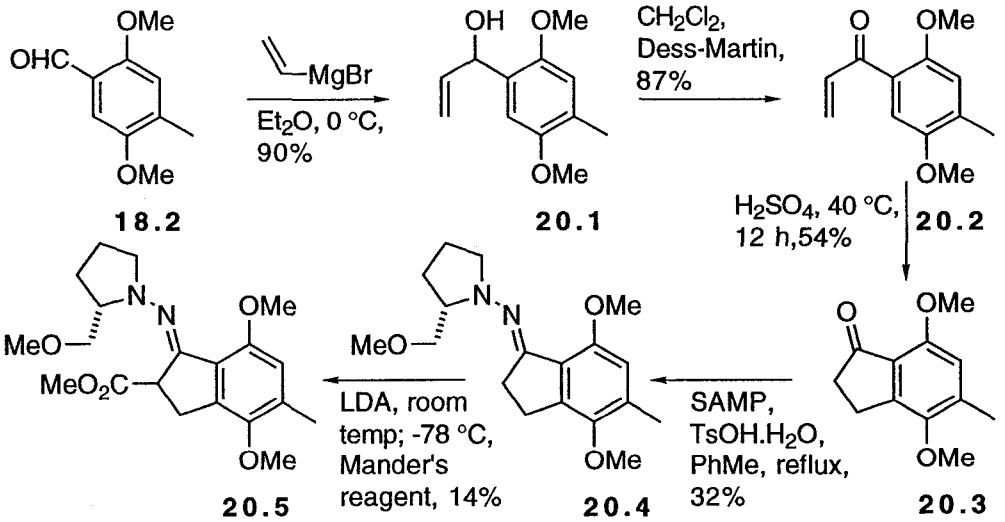
In the present route, formation of the 5-membered ring at an early stage avoids complications engendered by the

presence of the (2'-oxyethyl) side chain, and a considerable shortening of the synthesis results. Our attempts to effect oxidative cleavage of the allyl side chain of **19.8** illustrate the significant improvement that can be achieved in the Lemieux-Johnson oxidation by controlling the pH. This method deserves to be better known.

## Studies on the synthesis of optically pure puraquinonic acid

### (a) Attempts to use SAMP derivatives

Our first approach was based on the SAMP derivative[29] of indanone **20.3**, which was prepared from **18.2**, as shown in Scheme 20, the experiments being of exactly the same type as those used previously. Our choice of **20.3** was forced on us because we were unable to make the SAMP derivative of **16.4**,

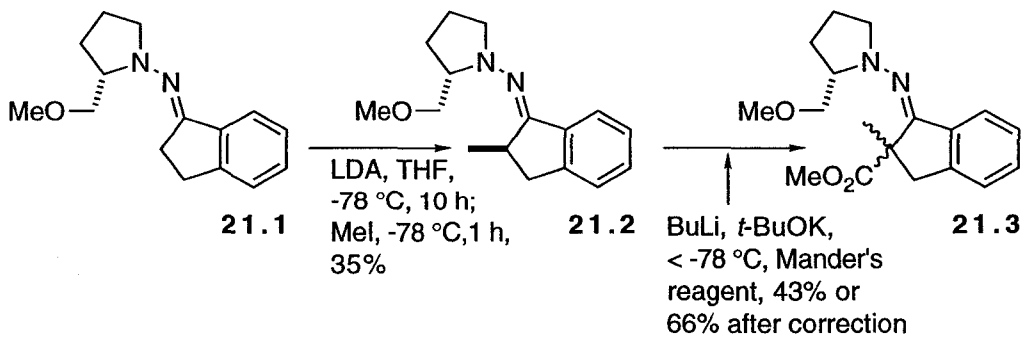


**Scheme 20**

presumably because the carbonyl is too hindered. The SAMP

derivative of **20.3** was obtained in only 32% yield. The inefficiency of the process is due to steric or electronic factors generated by the *peri* MeO group, since indanone itself gave the SAMP derivative in 94% yield under the same conditions. When **20.4** was deprotonated with LDA in THF at -78 °C for 40 min and treated with Mander's reagent or with $D_2O$, we observed no acylation or deuteration products. However, when the LDA-**20.4** mixture was warmed to room temperature and kept at room temperature for 3 h before addition of Mander's reagent at -78 °C, the desired acylation product was indeed formed – but only in 14% yield and as a mixture of isomers. In retrospect, we should have added a second equivalent of LDA (since the desired product is more acidic than the initial anion, and must have been deprotonated by it); in that case, protonation on workup may have occurred in an asymmetric fashion.

We decided to examine the simpler SAMP hydrazone **21.1** (Scheme 21), which was easily made from indanone. Standard methylation gave a single isomer, which we assume to have the

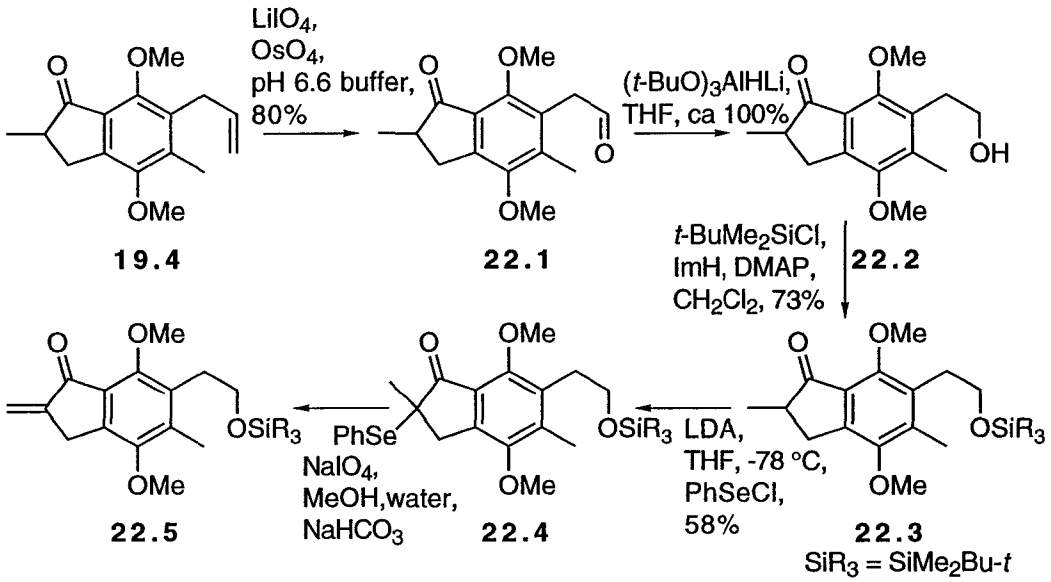


**Scheme 21**

stereochemistry shown. Deprotonation and acylation with Mander's reagent gave **21.3** in 43% yield (or 66% after correction for recovered **21.2**). Unfortunately, the material was a 1:1 mixture of diastereoisomers; we conclude that the SAMP derivatives are unsuitable for our purpose, and we turned our attention to the original plan summarized in Scheme 3.

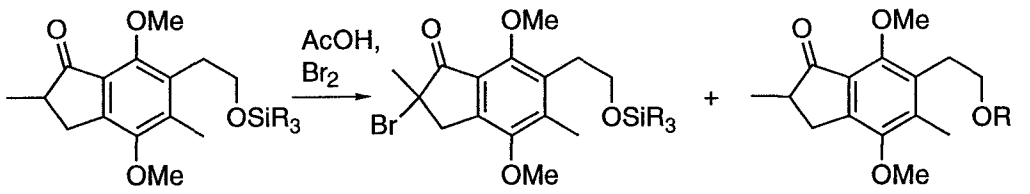
**(b) Approach based on an optically pure allylic alcohol**

In order to implement the original plan (see Scheme 3), the pendant double bond in ketone **19.4** was first cleaved (Scheme 22), using $LiIO_4$-$OsO_4$. With this reagent combination[27] the yield was 80%, while under the standard Lemieux-Johnson conditions the yield was 64%. The resulting aldehyde group was selectively reduced to an alcohol, which



**Scheme 22**

was then protected by silylation (**19.4** → **22.1** → **22.2** → **22.3**). Phenylselenation in the usual way gave keto selenide **22.4**, but when this was treated with $NaIO_4$ it was recovered largely unchanged together with a trace of the exocyclic olefin **22.5**. We decided, therefore, to introduce the required double bond by bromination-dehydrobromination, and so ketone **22.3** was treated with $Br_2$ in AcOH (Scheme 23). Some of the desired **23.1** was obtained, but there was extensive desilylation and acylation (**23.1**:**23.2**:**22.2** = 1:3.8:3 by $^1H$ NMR). To avoid these side reactions, we decided to perform the bromination-dehydrobromination before



**22.3**
$SiR_3 = SiMe_2Bu\text{-}t$

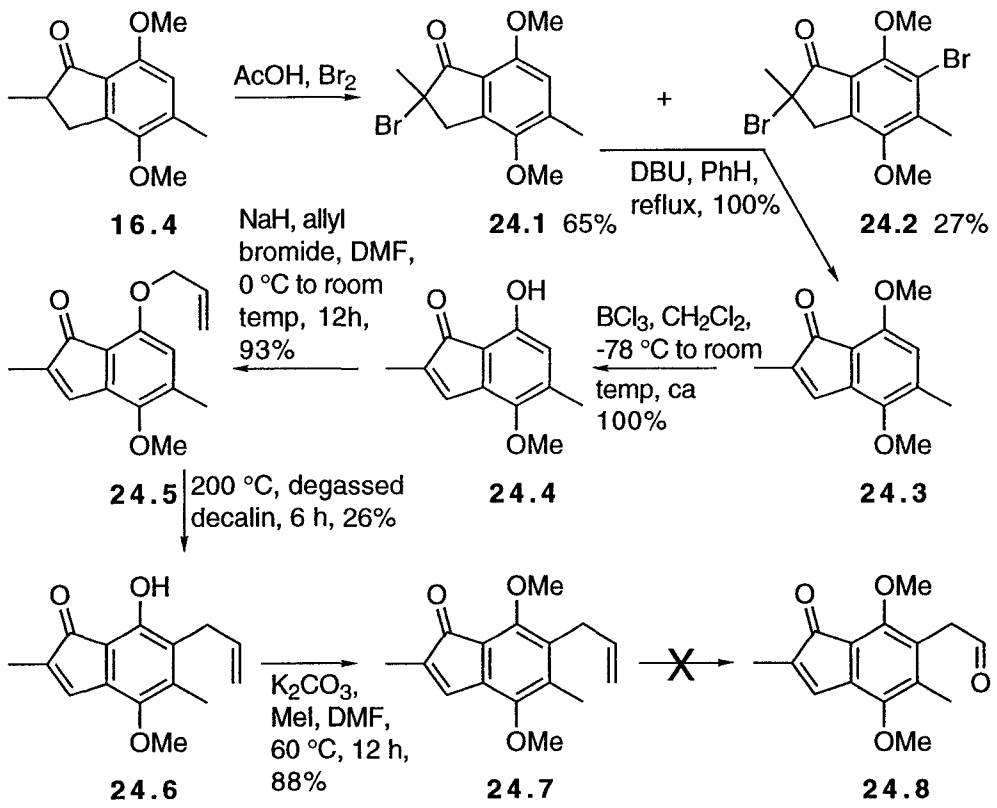
**23.1**

**23.2** R = Ac,
R = H (≡ **22.2**)

**Scheme 23**

elaborating the oxyethyl sidechain.

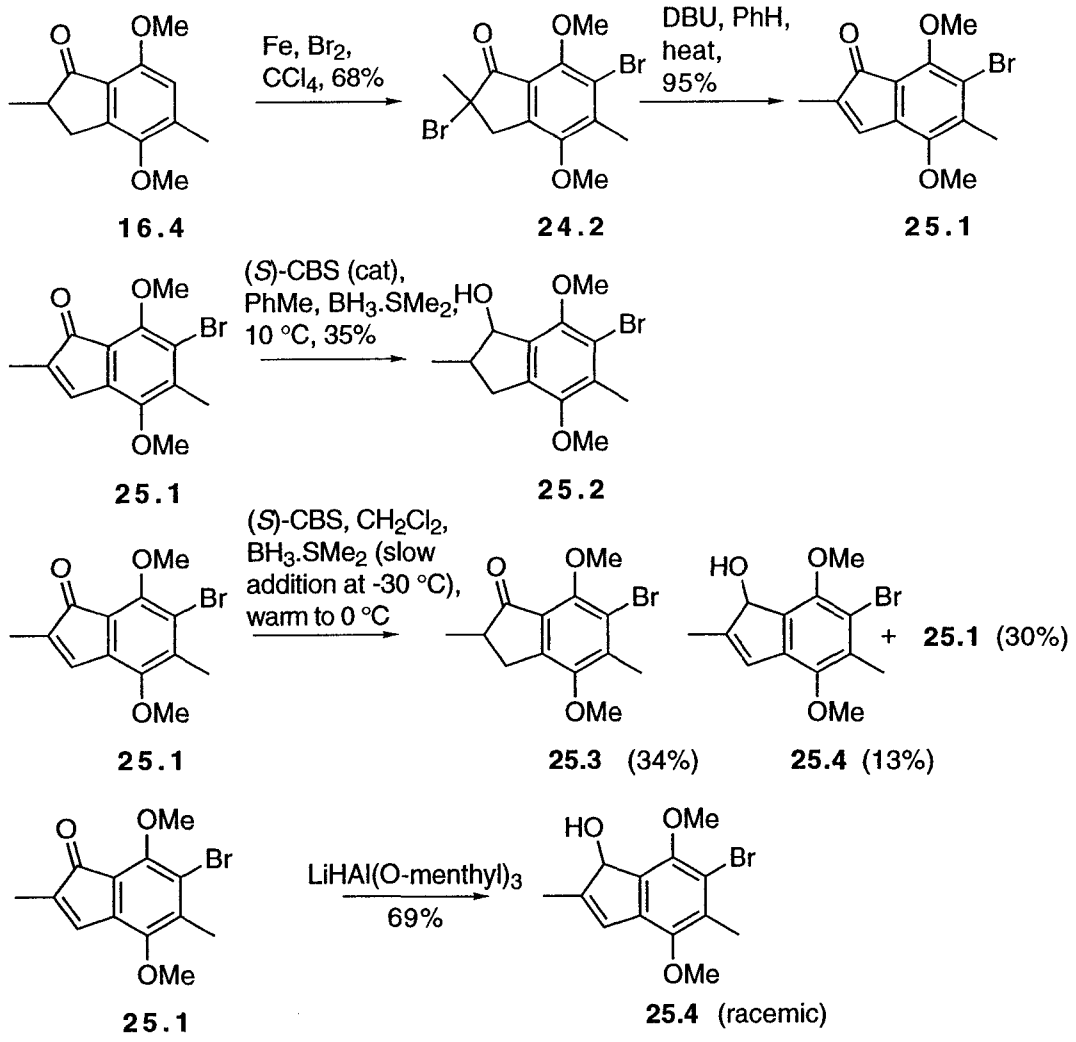
Bromination of **16.4** gave mainly the monobromide **24.1** (Scheme 24, 65%), but an appreciable amount (25%) of the dibromide **24.2** was also formed. When **24.1** was heated with DBU in PhH, it was smoothly converted into the desired enone **24.3**. This was selectively demethylated ($BCl_3$, ca 100%), and subjected to our usual sequence of allylation, Claisen rearrangement, and remethylation, bringing the work to the stage of compound **24.7**. When we attempted to cleave the



**Scheme 24**

pendant double bond, using $OsO_4$-$NaIO_4$ or $LiIO_4$-$OsO_4$-buffer, the starting material was destroyed and we failed to obtain the desired **24.8**.

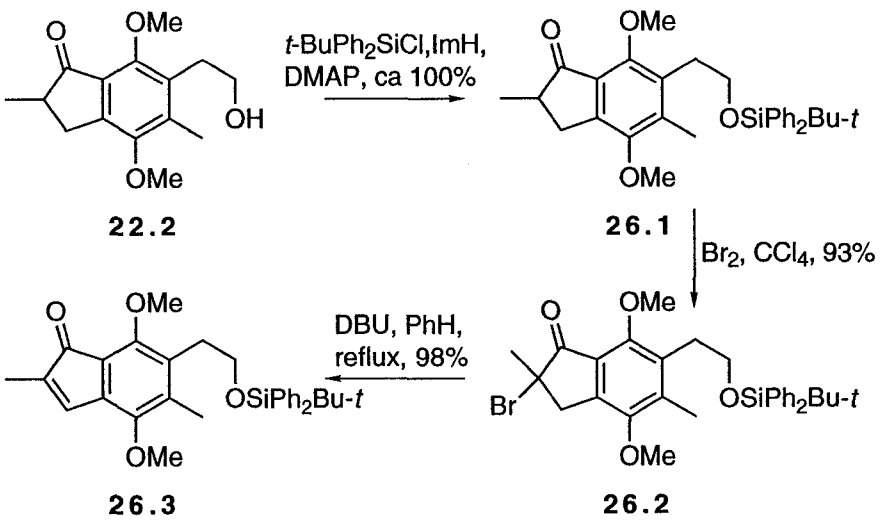
In order to avoid the problem of cleaving the double bond, ketone **16.4** was now dibrominated, so as to afford **24.2** under conditions that gave the compound in 68% yield. Dehydrobromination as before, using DBU, then gave the enone **25.1**. The purpose of having in place the aromatic Br is to provide a means for eventually attaching an oxyethyl sidechain. Treatment of this enone (**25.1**) with (*S*)-CBS-$BH_3.SMe_2$ in PhMe generated the saturated ketone **25.3** instead of the allylic alcohol **25.4**. With $CH_2Cl_2$ as the solvent, and



**Scheme 25**

slow addition of the borane, **25.3**, a small amount of **25.4** (of unestablished chirality), and an appreciable amount of starting **25.1** were obtained. Compound **25.1** is not very soluble in $CH_2Cl_2$ or PhMe, and this fact limits the conditions that can be used. Although LiAlH(*O*-menthyl)$_3$ did reduce ketone **25.1** to the allylic alcohol, the material was found to be racemic by $^1H$ NMR measurements, using a chiral shift reagent. An attempt to make the Mosher ester of **25.4** was unsuccessful.

At this point we decided to work with the oxyethyl sidechain already in place before again attempting to effect an asymmetric reduction of the enone system. We suspected that the solubility problems associated with use of **25.1** could thereby be avoided. We had previously (see Scheme 23) found that an $OSiMe_2Bu\text{-}t$ group was not robust enough to withstand our bromination conditions, and so we took **22.2** and



**Scheme 26**

subjected it to silylation with $t\text{-}BuPh_2SiCl$, and then to bromination, and dehydrobromination, so as to form the enone **26.3**. While we had planned to carry out a thorough investigation on the asymmetric reduction of the ketone carbonyl of **26.3**, another researcher in this laboratory embarked on a more obviously promising approach to the required allylic alcohol. Since his method was successful, we did not continue our work with **26.3**; instead we began the project described in the next chapter.

## Conclusion

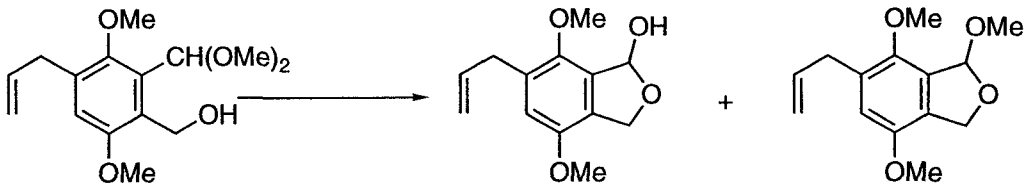
Our research constitutes the first synthesis of puraquinonic acid, for which we have developed two routes. During this work the superiority of $LiIO_4$-$OsO_4$ in a pH 6.6 buffer over the standard Lemieux-Johnson procedure was demonstrated, as well as the beneficial effect of 2,6-pyridinedicarboxylic acid *N*-oxide on the behavior of $(NH_4)_2Ce(NO_3)_6$ for oxidation of *p*-dimethoxy benzenes.

Our preliminary studies on making optically pure material have revealed some shortcomings of certain standard approaches. In particular the SAMP/RAMP method does not appear to be applicable to sterically hindered ketones. Other work in this laboratory has led to the synthesis of optically pure material and the establishment of the absolute configuration.[30]

## EXPERIMENTAL SECTION

**General Procedures.** Unless stated to the contrary, the procedures described in the Experimental Section of Chapter 1 of this thesis were followed.

**1,3-Dihydro-4,7-dimethoxy-6-(2-propenyl)isobenzofuran-1-ol (6.2) and 1,3-Dihydro-1,4,7-trimethoxy-6-(2-propenyl)isobenzofuran (6.3).**



**6.1** **6.2** **6.3**

Dilute hydrochloric acid (0.1 M, 10 mL) was added dropwise to a stirred solution of acetal **6.1** (1.304 g, 4.624 mmol) in dioxane (10 mL). Stirring was continued for 12 h, by which time all the starting material had been consumed (TLC control, silica, 2:3 EtOAc-hexane). The mixture was neutralized with saturated aqueous $NaHCO_3$ and the aqueous layer was extracted with $CH_2Cl_2$, washed with water and brine, dried ($MgSO_4$), and evaporated. Flash chromatography of the residue over silica gel (2.5 x 18 cm), using 1:4 EtOAc-hexane, gave lactol **6.2** (778.1 mg, 71%) as a white solid and the corresponding methyl ether [1,3-dihydro-1,4,7-trimethoxy-6-(2-propenyl)isobenzofuran] (276.7 mg, 24%) as a colorless

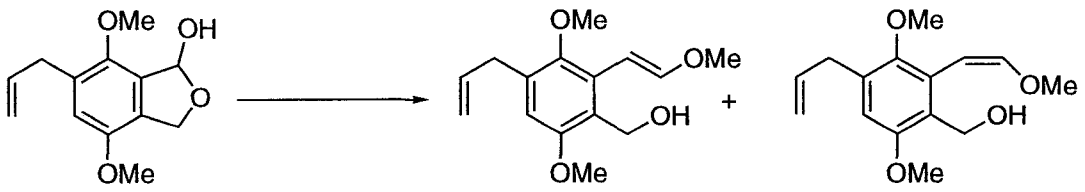
oil. Lactol **6.2** had: mp 157.5 °C; FTIR ($CH_2Cl_2$ cast) 3335 $cm^{-1}$; $^1H$ NMR ($CD_2Cl_2$, 200 MHz) δ 3.31-3.45 (m, 3 H), 3.78 (s, 3 H), 3.82 (s, 3 H), 4.88 (d, *J* = 12 Hz, 2 H), 5.01-5.18 (m, 2 H), 5.88-6.09 (m, 1 H), 6.59 (dd, *J* = 6, 1.8 Hz, 1 H), 6.7 (s, 1 H); $^{13}C$ NMR ($CD_2Cl_2$, 100.6 MHz) δ 34.4 (t'), 56.0 (q'), 61.4 (q'), 70.6 (t'), 101.0 (d'), 113.7 (d'), 115.7 (t'), 127.7 (s'), 132.3 (s'), 133.5 (s'), 137.6 (d'), 147.4 (s'), 149.7 (s'); exact mass (HR electrospray) *m/z* calcd for $C_{13}H_{16}NaO_4$ (M + Na) 259.09463, found 259.09467.

1,3-Dihydro-1,4,7-trimethoxy-6-(2-propenyl)isobenzofuran (**6.3**) had: $^1H$ NMR ($CD_2Cl_2$, 200 MHz) δ 3.41 (s, 3 H), 3.42 (m, 2 H), 3.76 (s, 3 H), 3.81 (s, 3 H), 4.82-5.15 (m, 4 H), 5.85-6.12 (m, 1 H), 6.25 (d, *J* = 3 Hz, 1 H), 6.68 (s, 1 H); $^{13}C$ NMR ($CD_2Cl_2$, 50.3 MHz) δ 35.9 (t'), 55.8 (q'), 57.5 (q'), 62.7 (q'), 72.3 (t'), 108.5 (d'), 115.2 (d'), 117.3 (t'), 129.8 (s'), 132.1 (s'), 134.7 (s'), 139.3 (d'), 149.0 (s'), 151.1 (s'); exact mass (HR electrospray) *m/z* calcd for $C_{14}H_{18}NaO_4$ (M + Na) 273.11028, found 273.10998.

The 1,3-dihydro-1,4,7-trimethoxy-6-(2-propenyl)isobenzofuran (**6.3**) was hydrolyzed to lactol **6.2**, as follows. Dilute hydrochloric acid (0.1 M, 12 mL) was added dropwise to a stirred solution of the lactol methyl ether (1.146 g, 4.58 mmol) in dioxane (10 mL). Stirring was continued for 12 h, by which time all the starting material had been consumed (TLC control, silica, 2:3 EtOAc-hexane). The mixture was neutralized with saturated aqueous $NaHCO_3$ and the aqueous layer was extracted with $CH_2Cl_2$, washed with water and brine,

dried ($MgSO_4$), and evaporated. Flash chromatography of the residue over silica gel (2.5 x 18 cm), using 1:4 EtOAc-hexane, gave lactol **6.2** (737 mg, 68%).

**(*E*)- and (*Z*)-[3,6-Dimethoxy-2-(2-methoxyethenyl)-4-(2-propenyl)phenyl]methanol (*E*-6.4) and (*Z*-6.4).**[6]



**6.2** ***E*-6.4** ***Z*-6.4**

(Methoxymethyl)triphenylphosphonium bromide (511.3 mg, 1.483 mmol) was placed in a long-necked flask and dry THF (2 mL) was added. The white slurry was stirred and cooled to -78 °C, and $(Me_3Si)_2NK$ (0.5 M solution in PhMe, 1.7 mL, 0.85 mmol) was added dropwise over 5 min. The resulting red slurry was stirred at -78 °C for 2 h, and a solution of lactol **6.2** (100.0 mg, 0.424 mmol) in dry THF (1 mL plus 1 mL as a rinse) was added dropwise over ca 5 min. The resulting pale orange solution was stirred for 10 h without recharging the cold bath. The resulting white slurry was filtered off using a sintered disc, and washed with EtOAc. Evaporation of the filtrate and flash chromatography of the residue over silica gel (2.5 x 15 cm), using 1:4 EtOAc-hexane, gave the isomeric enol ethers (*E*)-**6.4** (70.8 mg, 63%) and (*Z*)-**6.4** (33.5 mg, 30%) as colorless oils. Compound (*E*)-**6.4** had:

FTIR ($CH_2Cl_2$ cast) 3462 $cm^{-1}$; $^1H$ NMR ($CD_2Cl_2$, 400 MHz) δ 2.16 (t, *J* = 6.9 Hz, 1 H), 3.40 (dt, *J* = 1.4, 6.6 Hz, 2 H), 3.62 (s, 3 H), 3.71 (s, 3 H), 3.84 (s, 3 H), 4.65 (d, *J* = 6.9 Hz, 2 H), 5.05-5.14 (m, 2 H), 5.85 (d, *J* = 15 Hz, 1 H), 5.92-6.05 (m, 1 H), 6.61 (s, 1 H), 6.99 (d, *J* = 15 Hz, 1 H); $^{13}C$ NMR ($CD_2Cl_2$, 75.5 MHz) δ 34.7 (t'), 56.1 (q'), 56.7 (q'), 58.0 (t'), 60.4 (q'), 98.0 (d'), 110.1 (d'), 115.9 (t'), 126.0 (s'), 130.8 (s'), 133.4 (s'), 137.7 (d'), 150.1 (s'), 153.1 (d'), 154.9 (s'); exact mass (HR electrospray) *m/z* calcd for $C_{15}H_{20}NaO_4$ (M + Na) 287.12593, found 287.12595.

Compound (*Z*)-**6.4** had: FTIR ($CH_2Cl_2$ cast) 3462 $cm^{-1}$; $^1H$ NMR ($CD_2Cl_2$, 300 MHz) δ 2.78 (t, *J* = 6.9 Hz, 1 H), 3.40 (dt, *J* = 1.4, 6.6 Hz, 2 H), 3.63 (s, 3 H), 3.64 (s, 3 H), 3.82 (s, 3 H), 4.54 (d, *J* = 6.9 Hz, 2 H), 5.05-5.14 (m, 2 H), 5.41 (d, *J* = 6.8 Hz, 1 H), 5.93-6.23 (m, 1 H), 6.25 (d, *J* = 6.8 Hz, 1 H), 6.67 (s, 1 H); $^{13}C$ NMR ($CD_2Cl_2$, 100.6 MHz) δ 34.5 (t'), 56.1 (q'), 59.2 (t'), 60.3 (q'), 61.0 (q'), 100.8 (d'), 111.3 (d'), 116.0 (t'), 127.7 (s'), 129.1 (s'), 133.0 (s'), 137.7 (d'), 148.4 (d'), 150.2 (s'), 154.8 (s'); exact mass (HR electrospray) *m/z* calcd for $C_{15}H_{20}NaO_4$ (M + Na) 287.12593, found 287.12572.

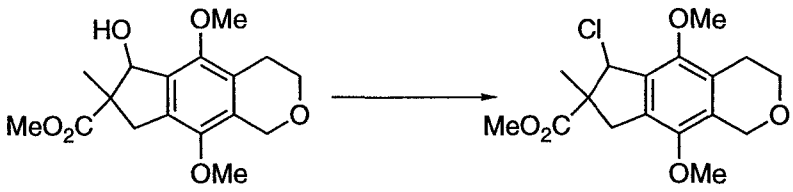
$NaBH_4$ (95 mg, 2.52 mmol) was added in several portions over 40 min to a stirred and cooled (0 °C) solution of ketone **13.6** in dry MeOH (20 mL). After 1 h at 0 °C, water (2 mL) was added, and the resulting cooled solution was stirred for 30 min, and then extracted with EtOAc. The combined organic extracts were dried ($MgSO_4$) and evaporated. Flash chromatography of the residue over silica gel (2 x 20 cm), using 1:24:75 MeOH-EtOAc-hexanes, gave alcohols **14.1** (268 mg, 99%) as a colorless oil: FTIR ($CHCl_3$ cast) 3430, 1729 $cm^{-1}$;

$^1$H NMR ($CDCl_3$, 400 MHz) (mixture of diastereoisomers) δ 1.25 (s, 0.71), 1.35 (s, 2.4 H), 1.59 (s, 0.91 H), 2.60 (d, *J* = 7.8 Hz, 0.69 H), 2.68-2.86 (m, 2 H), 2.92 (d, *J* = 15.8 Hz, 0.8 H), 3.37 (d, *J* = 15.8 Hz, 0.8 H), 3.73-3.96 (m including three s, 10.5 H in all), 4.73 (s, 2 H), 5.09 (d, *J* = 4.5 Hz, 0.16 H); $^{13}$C NMR ($CDCl_3$, 100.6 MHz) (mixture of diastereoisomers) δ 18.3 (q'), 23.2 (t'), 23.3 (t'), 23.4 (q'), 37.2 (t'), 38.7 (t'), 52.3 (q'), 52.4 (q'), 55.2 (t'), 55.4 (t'), 59.8 (q'), 60.6 (q'), 61.4 (q'), 64.6 (t'), 64.7 (t'), 77.8 (d'), 79.3 (d'), 126.7 (s'), 126.9 (s'), 129.0 (s'), 129.5 (s'), 129.7 (s'), 131.2 (s'), 132.3 (s'), 133.0 (s'), 148.4 (s'), 150.7 (s'), 151.3 (s'), 176.9 (s'); exact mass *m/z* calcd for $C_{17}H_{22}O_6$ 322.1416, found 322.1413.

**Methyl 1-Chloro-2,3,7,8-tetrahydro-5*H*-4,9-dimethoxy-2-methyl-6-oxacyclopenta[b]naphthalene-2-carboxylate (14.2).**



**14.1** **14.2**

$SOCl_2$ (121 μL, 1.66 mmol) was added dropwise to a stirred and cooled (0 °C) solution of alcohols **14.1** (268 mg, 0.832 mmol) and $Et_3N$ (232 μL, 1.66 mmol) in dry $CH_2Cl_2$ (5 mL). After 30 min the cold bath was removed, and the mixture was

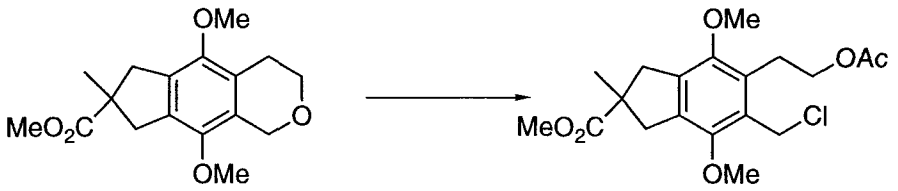
refluxed for 4 h. The mixture was cooled and poured into water (10 mL). The aqueous layer was extracted with EtOAc, and the combined organic extracts were washed with water, dried ($MgSO_4$), and evaporated. Flash chromatography of the residue over silica gel (1 x 20 cm), using 1:5 EtOAc-hexanes, gave chlorides **14.2** [153 mg, 54% or 93% after correction for recovered starting material (114 mg)] as a colorless liquid: FTIR ($CHCl_3$ cast) 1737 $cm^{-1}$; $^1H$ NMR ($CDCl_3$, 400 MHz) (mixture of diastereoisomers) $\delta$ 1.31 (s, 1.4 H), 1.61 (s, 2.0 H), 2.69-2.90 [m including d ($J$ = 20.6 Hz) at $\delta$ 2.85, 2.46 H in all], 2.96 (d, $J$ = 15.6 Hz, 0.59 H), 3.60-3.65 [m including s and d ($J$ = 20.6 Hz), 2.3 H in all], 3.75-4.00 [m including singlets at $\delta$ 3.78, 3.81, 3.83, 3.89, 3.90 and d at $\delta$ 3.82 ($J$ = 15.6 Hz), 9.4 H in all], 4.68-4.79 (m, 2 H), 5.27 (s, 0.38 H), 5.86 (s, 0.46 H); $^{13}C$ NMR ($CDCl_3$, 100.6 MHz) (mixture of diastereoisomers) $\delta$ 21.2 (q'), 23.3 (t'), 23.8 (q'), 36.7 (t'), 37.9 (t'), 52.3 (q'), 52.8 (q'), 56.9 (t'), 57.4 (t'), 59.8 (q'), 59.9 (q'), 60.8 (q'), 60.9 (q'), 64.58 (t'), 64.61 (t'), 65.9 (d'), 66.0 (d'), 127.1 (s'), 127.2 (s'), 130.1 (s'), 130.2 (s'), 130.4 (s'), 131.1 (s'), 132.2 (s'), 133.8 (s'), 147.9 (s'), 149.0 (s'), 149.8 (s'), 150.4 (s'), 173.7 (s'), 175.4 (s'); exact mass $m/z$ calcd for $C_{17}H_{21}{}^{35}ClO_5$ 340.1078, found 340.1080.

**Methyl 2,3,7,8-Tetrahydro-5*H*-4,9-dimethoxy-2-methyl-6-oxacyclopenta[b]naphthalene-2-carboxylate (14.3).**

**14.2** **14.3**

A mixture of chloride **14.2** (138 mg, 0.405 mmol), $Bu_3SnH$ (220 μL, 0.810 mmol) and AIBN (10 mg, 0.061 mmol) in dry PhMe (5 mL) was refluxed for 3 h. The mixture was cooled and applied to a column of silica gel (1 x 20 cm), which was developed successively with hexanes, 1:20 EtOAc-hexanes, 1:10 EtOAc-hexanes and 1:5 EtOAc-hexanes, to give **14.3** as a colorless oil contaminated with tin residues. Flash chromatography over silica gel, using 1:5 EtOAc-hexanes, gave ester **14.3** (118 mg, 95%) as a colorless oil: FTIR ($CHCl_3$ cast) 1731 $cm^{-1}$; $^1H$ NMR ($CDCl_3$, 360 MHz) δ 1.36 (3 H), 2.76 (t, $J$ = 5.6 Hz, 2 H), 2.87 (d, $J$ = 15.7 Hz, 2 H), 3.46 (dd, $J$ = 15.8, 3.0 Hz, 2 H), 3.73-3.74 (overlapping singlets at δ 3.73, 3.735, 3.74, 9 H in all), 3.83-3.94 (m, 2 H), 4.74 (s, 2 H); $^{13}C$ NMR ($CDCl_3$, 50.3 MHz) δ 23.2 (t'), 25.0 (q'), 41.0 (t'), 41.2 (t'), 50.1 (t'), 52.2 (q'), 59.6 (q'), 59.7 (q'), 64.5 (t'), 64.7 (t'), 125.8 (s'), 126.9 (s'), 130.7 (s'), 131.9 (s'), 148.3 (s'), 150.0 (s'), 177.7 (s'); exact mass $m/z$ calcd for $C_{17}H_{22}O_5$ 306.1467, found 306.1464.

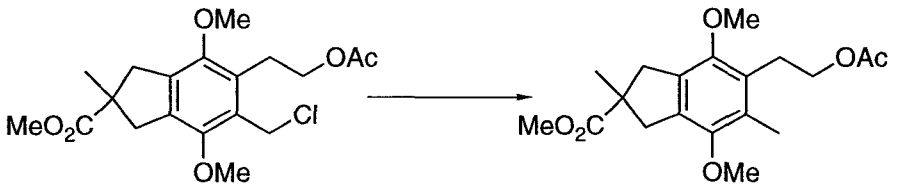
**Methyl 6-[2-(Acetyloxy)ethyl]-5-chloromethyl-4,7-dimethoxy-2-methylindan-2-carboxylate (14.4).**



**14.3** **14.4**

$ZnCl_2$ (5.5 mg, 10 mol%) and AcCl (82 μL, 1.16 mmol) were added to a stirred solution of isochroman **14.3** (118 mg, 0.39 mmol) in dry $CH_2Cl_2$ (6 mL), and the mixture was refluxed (Ar atmosphere) for 6 h. The solvent was then evaporated, and flash chromatography of the residue over silica gel (1.8 x 20 cm), using 1:4 EtOAc-hexanes, gave acetate **14.4** (131 mg, 88%) as a colorless oil: FTIR ($CDCl_3$ cast) 1736 $cm^{-1}$; $^1H$ NMR ($CDCl_3$, 360 MHz) δ 1.36 (s, 3 H), 2.05 (s, 3 H), 2.89 (dd, $J$ = 16.1, 2.8 Hz, 2 H), 3.05 (t, $J$ = 7.2 Hz, 2 H), 3.47 (d, $J$ = 10.3 Hz, 1 H), 3.51 (d, $J$ = 10.5 Hz, 1 H), 3.74 (s, 3 H), 3.78 (s, 3 H), 3.84 (s, 3 H), 4.21 (t, $J$ = 7.6 Hz, 2 H), 4.76 (AB q, $\Delta\nu_{AB}$ = 25.5 Hz, $J$ = 10.9 Hz, 2 H); $^{13}C$ NMR ($CDCl_3$, 50.3 MHz) δ 21.0 (q'), 25.0 (q'), 26.1 (t'), 38.2 (t'), 41.2 (t'), 41.6 (t'), 50.1 (t'), 52.2 (q'), 60.2 (q'), 60.9 (q'), 64.1 (t'), 128.9 (s'), 133.5 (s'), 135.2 (s'), 151.2 (s'), 151.6 (s'), 170.9 (s'), 177.5 (s') (two signals in this spectrum overlap); exact mass $m/z$ calcd for $C_{19}H_{25}{}^{35}ClO_6$ 384.1340, found 384.1337.

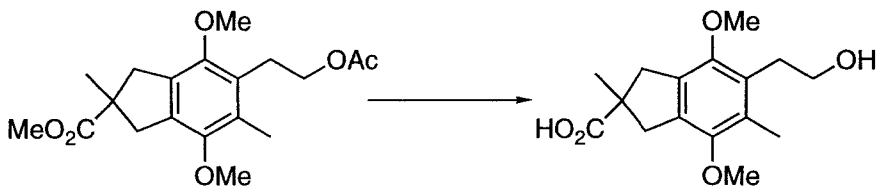
**Methyl 6-[2-(Acetyloxy)ethyl]-4,7-dimethoxy-2,5-dimethylindan-2-carboxylate (14.5).**



**14.4** **14.5**

$Bu_3SnH$ (136 μL, 0.51 mmol) and AIBN (7 mg, 15 mol%), were added to a stirred solution of chloride **14.4** (97.8 mg, 0.25 mmol) in PhMe (6 mL), and the mixture was refluxed for 1.5 h. Evaporation of the solvent and flash chromatography of the residue over silica gel (1.8 x 12 cm), using 1:9 EtOAc-hexanes, gave acetate **14.5** contaminated with tin residues. Flash chromatography over silica gel (1.8 x 12 cm), using 1:9 EtOAc-hexanes, gave acetate **14.5** (77.3 mg, 87%) as a colorless oil: FTIR ($CDCl_3$ cast) 1735 $cm^{-1}$; $^1H$ NMR ($CDCl_3$, 360 MHz) δ 1.35 (s, 3 H), 2.05 (s, 3 H), 2.23 (s, 3 H), 2.87 (dd, $J$ = 15.4, 4.0 Hz, 2 H), 2.96 (dt, $J$ = 7.7, 2.2 Hz, 2 H), 3.46 (dd, $J$ = 15.8, 12.9 Hz, 2 H), 3.69 (s, 3 H), 3.73 (s, 3 H), 3.76 (s, 3 H), 4.14 (t, $J$ = 7.7 Hz, 2 H); $^{13}C$ NMR ($CDCl_3$, 50.3 MHz) δ 12.1 (q'), 21.1 (q'), 25.2 (q'), 26.6 (t'), 41.1 (t'), 41.6 (t'), 50.1 (t'), 52.2 (q'), 60.0 (q'), 60.2 (q'), 63.8 (t'), 127.9 (s'), 129.3 (s'), 131.1 (s'), 133.3 (s'), 150.9 (s'), 151.5 (s'), 171.1 (s'), 177.8 (s'); exact mass $m/z$ calcd for $C_{19}H_{26}O_6$ 350.1730, found 350.1727.

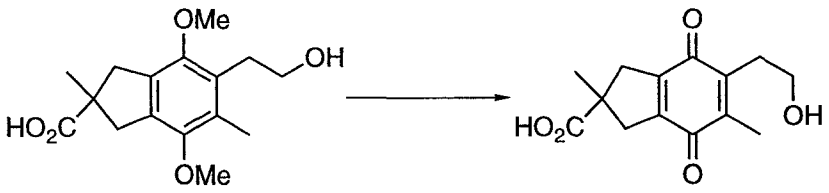
**Methyl 6-(2-Hydroxyethyl)-4,7-dimethoxy-2,5-dimethylindan-2-carboxylate (14.6).**



**14.5** **14.6**

$LiOH.H_2O$ (28.0 mg, 0.66 mmol) was added to a stirred solution of ester **14.5** (15.3 mg, 0.044 mmol) in 1:1 dioxane-water (4 mL). After 3 h, the mixture was acidified with hydrochloric acid (1.0 M, 4 mL) and then extracted with EtOAc. The combined organic extracts were dried ($MgSO_4$) and evaporated. Flash chromatography of the residue over silica gel (0.8 x 20 cm), using 1:19 MeOH-$CH_2Cl_2$, gave alcohol **14.6** (11.6 mg, 90%) as a white solid: FTIR ($CHCl_3$ cast) 1701 $cm^{-1}$; $^1H$ NMR ($CDCl_3$, 400 MHz) $\delta$ 1.41 (s, 3 H), 2.09 (s, 1 H), 2.21 (s, 3 H), 2.86-2.94 (m, 4 H), 3.47-3.55 (m, 2 H), 3.70 (s, 3 H), 3.73-3.80 (m containing s at $\delta$ 3.76, 5 H in all), 3.87 (d, $J$ = 11.7 Hz, 1 H), 3.92 (d, $J$ = 11.6 Hz, 1 H), 4.11 (s, 3 H), 3.72-3.80 (m including s at $\delta$ 4.17, 5 H in all); $^{13}C$ NMR ($CDCl_3$, 50.3 MHz) $\delta$ 12.2 (q'), 25.0 (q'), 30.5 (t'), 41.1 (t'), 41.5 (t'), 50.0 (t'), 60.0 (q'), 60.2 (q'), 62.7 (t'), 129.1 (s'), 129.2 (s'), 131.2 (s'), 133.0 (s'), 151.1 (s'), 151.2 (s'), 183.2 (s'); exact mass $m/z$ calcd for $C_{16}H_{22}O_5$ 294.1467, found 294.1467.

**2,3,4,7-Tetrahydro-5-(2-hydroxyethyl)-2,6-dimethyl-4,7-dioxo-1*H*-indene-2-carboxylic acid (puraquinonic acid) (1.1).**



**14.6** **1.1**

An ice-cold solution of $Ce(NH_4)_2(NO_3)_6$ (277 mg, 0.506 mmol) in 1:1 MeCN-water (0.8 mL) was added slowly to a stirred and cooled (0 °C) solution of alcohol **14.6** (45.8 mg, 0.156 mmol) in 2:1 MeCN-water (0.9 mL) containing pyridine-2,6-dicarboxylic acid *N*-oxide (92.7 mg, 0.506 mmol). After 40 min, the mixture was diluted with water (5 mL), and extracted with $CH_2Cl_2$. The combined organic extracts were dried ($MgSO_4$) and evaporated. Flash chromatography over silica gel (1.8 x 20 cm), using $CH_2Cl_2$, gave quinone **1.1** (31.7 mg, 77%) as a brown liquid with $^1H$ and $^{13}C$ NMR identical, within experimental error, with the reported[1] values.

**Table 1 ($^1$H NMR spectrum of puraquinonic acid)**

| **Natural** | **Natural** | **Synthetic** | **Synthetic** |

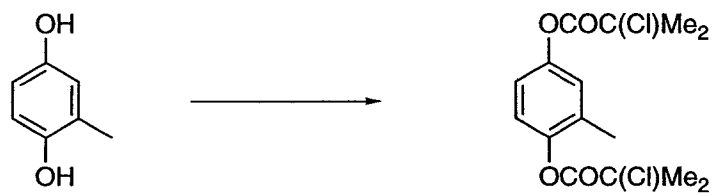
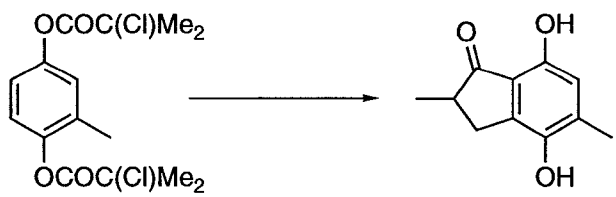
**1,4-Phenylene 2-Chloro-2-methylpropanoate (16.2).**



**16.1** **16.2**

α-Chloroisobutyroyl chloride (8.774 g, 62.2 mmol) was added dropwise 20 min, to a stirred and cooled (0 °C) solution of 2-methylhydroquinone **16.1** (3.513 g, 28.3 mmol) in pyridine (24 mL). The cold bath was removed and stirring was continued for 12 h. The pyridine was evaporated and the residue was dissolved in $Et_2O$ (300 mL), washed with hydrochloric acid (1.0 M, 3 x 100 mL) and water (100 mL), and dried ($MgSO_4$). Evaporation of the solvent gave crude diester **16.2** (8.372 g, 88%) as a brown solid which was used for the next step without purification: mp 52-58 °C; FTIR ($CDCl_3$ cast) 1758 $cm^{-1}$; $^{13}C$ NMR ($CDCl_3$, 50.3 MHz) (mixture of rotamers) δ 16.2 (q'), 16.3 (q'), 18.9 (q'), 19.0 (q'), 29.6 (q'), 29.7 (q'), 34.2 (q'), 64.3 (s'), 119.3 (d'), 119.9 (d'), 122.2 (d'), 122.4 (d'), 122.6 (d'), 122.8 (d'), 123.4 (d'), 123.6 (d'), 123.8 (d'), 124.0 (d'), 131.4 (s'), 131.8 (s'), 146.4 (s'), 146.8 (s'), 147.1 (s'), 148.0 (s'), 148.3 (s'), 169.7 (s'), 170.0 (s'), 175.1 (s'), 175.5 (s'); exact mass *m/z* calcd for $C_{15}H_{18}{}^{35}Cl_2O_4$ 332.0582, found 332.0586.

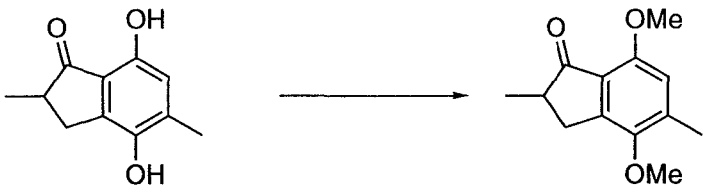
**4,7-Dihydroxy-2,5-dimethylindan-1-one (16.3).**



**16.2** **16.3**

Diester **16.2** (3.626 g, 10.9 mmol) and anhydrous $AlCl_3$ (5.782 g, 43.4 mmol) were thoroughly mixed and heated at 125 °C for 20 min and at 190 °C for 10 min. The mixture was cooled to room temperature, and the resulting solid was coarsely powdered and poured onto ice (100 g) containing concentrated hydrochloric acid (20 mL). The mixture was extracted with $Et_2O$ (5 x 100 mL) and the combined organic extracts were back-extracted with aqueous 10% NaOH (3 x 100 mL). The alkaline solution was acidified with concentrated hydrochloric acid and extracted with $Et_2O$ (3 x 100 mL). The combined organic extracts were dried ($MgSO_4$) and evaporated. Flash chromatography of the residue over silica gel (2.5 x 15 cm), using 1:4 EtOAc-hexanes, gave indanone **16.3** (900 mg, 43%), which was recrystallized from hot $CHCl_3$ as yellow crystals: mp 134-136 °C (lit.[23] 124-125 °C); FTIR ($CHCl_3$ cast) 1657, 3386 $cm^{-1}$; $^1H$ NMR ($CDCl_3$, 360 MHz) $\delta$ 1.31 (d, $J$ = 7.4 Hz, 3 H), 2.29 (s, 3 H), 2.58 (dd, $J$ = 17.0, 3.5 Hz, 1 H), 2.74-2.86 (m, 1 H), 3.27 (dd, $J$ = 17.1, 7.7 Hz, 1 H), 4.76 (s, 1 H), 6.59 (s, 1 H), 8.47 (s, 1 H); $^{13}C$ NMR ($CDCl_3$, 50.3 MHz) $\delta$ 16.3 (q'), 16.8 (q'), 31.5 (t'), 42.2 (d'), 115.97 (d'), 116.0 (d'), 120.4 (s'), 137.2 (s'), 143.8 (s'), 151.0 (s'), 211.6 (s'); exact *m/z* calcd for $C_{11}H_{12}O_3$ 192.0786, found 192.0787.

**4,7-Dimethoxy-2,5-dimethylindan-1-one (16.4).**



**16.3** **16.4**

MeI (4.03 mL, 64.7 mmol) was added dropwise to a stirred mixture of phenol **16.3** (1.243 g, 6.47 mmol) and $K_2CO_3$ (8.943 g, 64.7 mmol) in dry DMF (20 mL). The mixture was warmed to 70 °C, stirred for 5 h at this temperature, poured into brine, and extracted with $Et_2O$ (4 x 75 mL). The combined organic extracts were washed with water (50 mL) and brine (50 mL), dried ($MgSO_4$) and evaporated. Flash chromatography of the residue over silica gel (2.5 x 20 cm), using 1:5 EtOAc-hexanes, gave methyl ether **16.4** (914 mg, 64%) as a colorless oil: FTIR ($CDCl_3$ cast) 1707 $cm^{-1}$; $^1H$ NMR ($CDCl_3$, 360 MHz) $\delta$ 1.27 (d, $J$ = 7.3 Hz, 3 H), 2.34 (s, 3 H), 2.59-2.67 (m, containing a doublet of a doublet at 2.62, $J$ = 18.6, 3.8 Hz, 2 H in all), 3.28-3.35 (m, 1 H), 3.76 (s, 3 H), 3.88 (s, 3 H), 6.59 (s, 1 H); $^{13}C$ NMR ($CDCl_3$, 125.7 MHz) $\delta$ 16.7 (q'), 16.8 (q'), 31.5 (t'), 42.3 (q'), 55.8 (q'), 60.0 (d'), 111.9 (d'), 123.5 (s'), 139.9 (s'), 147.2 (s'), 148.7 (s'), 153.9 (s'), 206.3 (s'); exact mass $m/z$ calcd for $C_{13}H_{16}O_3$ 220.1099, found 220.1101.

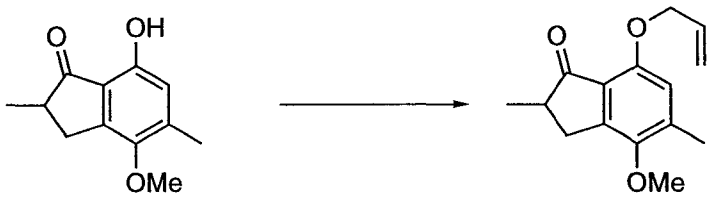
**7-Hydroxy-4-methoxy-2,5-dimethylindan-1-one (19.1).**

**16.4** **19.1**

$BCl_3$ (1.0 M in hexanes, 12.0 mL, 12.0 mmol) was added dropwise to a stirred and cooled (-78 °C) solution of methyl ether **16.4** (879 mg, 3.99 mmol) in dry $CH_2Cl_2$ (40.0 mL). The resulting pale yellow solution was stirred for 5 h without recharging the cold bath. The solution was recooled to 0 °C, water (15 mL) was added slowly, and the resulting mixture was extracted with EtOAc (4 x 50 mL). The combined organic extracts were dried ($MgSO_4$) and evaporated. Flash chromatography of the residue over silica gel (2 x 20 cm), using 1:5 EtOAc-hexanes, gave phenol **19.1** (802 mg, 97%) as a brown liquid: FTIR ($CDCl_3$ cast) 3342, 1675 $cm^1$; $^1H$ NMR ($CDCl_3$, 400 MHz) δ 1.30 (d, *J* = 7.4 Hz, 3 H), 2.29 (s, 3 H), 2.69 (dd, *J* = 17.3, 3.6 Hz, 1 H), 2.71-2.79 (m, 1 H), 3.38 (dd, *J* = 17.3, 7.6 Hz, 1 H), 3.77 (s, 3 H), 6.58 (s, 1 H), 8.73 (s, 1 H); irradiation of the $CH_3$ signal at δ 3.77 resulted in a 1% enhancement of the $CH_3$ signal at δ 2.29 and a 2% enhancement of the $CH_2$ signal at δ 2.69); $^{13}C$ NMR ($CDCl_3$, 125.7 MHz) δ 16.2 (q'), 16.9 (q'), 32.4 (t'), 41.9 (t'), 60.0 (d'), 116.0 (d'), 120.6 (s'), 141.8 (s'), 143.0 (s'), 148.1

(s'), 153.0 (s') (carbonyl signal not observed); exact mass *m/z* calcd for $C_{12}H_{14}O_3$ 206.0943, found 206.0945.

**2,5-Dimethyl-4-methoxy-7-(2-propenyloxy)indan-1-one (19.2).**

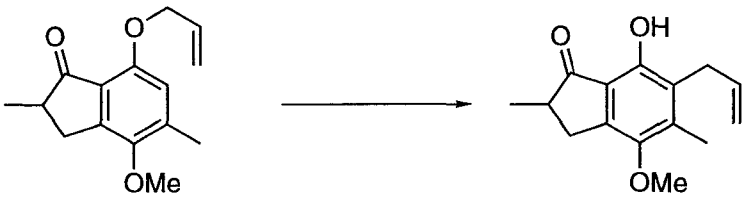


**19.1** **19.2**

A solution of phenol **19.1** (802 mg, 3.89 mmol) in dry DMF (14.0 mL) was added dropwise to a stirred and cooled (0 °C) suspension of NaH (95%, 108 mg, 4.28 mmol) in dry DMF (10.0 mL). The cold bath was removed and stirring was continued for 1 h. The mixture was recooled (0 °C) and allyl bromide (neat, 674 μL, 7.79 mmol) was added dropwise over 10 min. The cold bath was removed and stirring was continued for 1.5 h, and the mixture was poured into brine (50 mL) and extracted with $Et_2O$ (3 x 50 mL). The combined organic extracts were dried ($MgSO_4$) and evaporated. Flash chromatography of the residue over silica gel (2 x 20 cm), using 1:6 EtOAc-hexanes, gave allyl ether **19.2** (916 mg, 96% or 99% for recovered **19.1**, 26 mg) as a colorless liquid: FTIR ($CDCl_3$ cast) 1706, 1602 $cm^{-1}$; $^1H$ NMR ($CDCl_3$, 360 MHz) δ 1.21 (d, *J* = 7.3 Hz, 3 H), 2.26 (s, 3 H), 2.27-2.61 (m, 2 H), 3.22-3.30 (m, 1 H), 3.70 (d, *J* = 0.7 Hz, 3 H), 4.56 (dd, *J* =

4.9, 0.8 Hz, 2 H), 5.22 (dt, $J$ = 10.6, 1.2 Hz, 1 H), 5.46 (dt, $J$ = 17.3, 1.2 Hz, 1 H), 5.94-6.05 (m, 1 H), 6.53 (s, 1 H); $^{13}C$ NMR ($CDCl_3$, 50.3 MHz) δ 16.7 (two q'), 31.5 (t'), 42.4 (q'), 60.0 (q'), 69.4 (t'), 113.6 (d'), 117.6 (t'), 124.0 (s'), 132.7 (d'), 139.6 (s'), 147.0 (s'), 148.9 (s'), 152.9 (s'), 206.0 (s'); exact mass $m/z$ calcd for $C_{15}H_{18}O_3$ 246.1256, found 246.1264.

**7-Hydroxy-2,5-dimethyl-4-methoxy-6-(2-propenyl)-indan-1-one (19.3).**



**19.2** **19.3**

A solution of allyl ether **19.2** (793 mg, 3.03 mmol) in degassed decalin (5.0 mL) was refluxed for 8 h ($N_2$ atmosphere), and then cooled to room temperature. The mixture was loaded onto a dry silica gel column (2 x 15 cm), and flash chromatography, using hexanes and then 1:5 EtOAc-hexanes, gave **19.3** (536 mg, 67% or 75% after correction for recovered **19.2**, 85 mg) as a colorless oil: FTIR ($CDCl_3$ cast) 2933, 1674 $cm^{-1}$; $^1H$ NMR ($CDCl_3$, 360 MHz) δ 1.31 (d, $J$ = 7.4 Hz, 3 H), 2.27 (s, 3 H), 2.68 (dd, $J$ = 17.2, 3.6 Hz, 1 H), 2.75-2.80 (m, 1 H), 3.38 (dd, $J$ = 17.2, 7.6 Hz, 1 H), 3.42 (m, 2 H), 3.76 (s, 3 H), 4.93-5.02 (m, 2 H), 5.86-5.96 (m, 1

H), 9.04 (s, 1 H); $^{13}C$ NMR ($CDCl_3$, 50.3 MHz) δ 12.8 (q'), 16.2 (q'), 29.5 (t'), 32.2 (t'), 41.9 (d'), 60.2 (q'), 115.0 (t'), 119.9 (s'), 124.7 (s'), 135.0 (d'), 140.9 (s'), 141.0 (s'), 148.1 (s'), 151.4 (s'), 211.6 (s'); exact mass *m/z* calcd for $C_{15}H_{18}O_3$ 246.1256, found 246.1260.

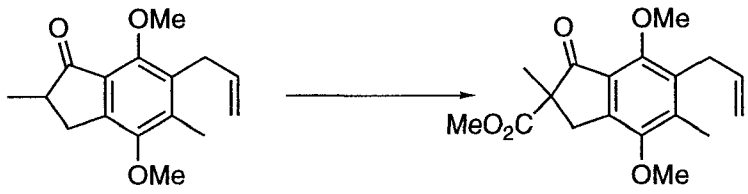
**4,7-Dimethoxy-2,5-dimethyl-6-(2-propenyl)indan-1-one (19.4).**

**19.3** **19.4**

MeI (0.66 mL, 10.5 mmol) was added dropwise to a stirred mixture of phenol **19.3** (514 mg, 2.10 mmol) and $K_2CO_3$ (1.456 g, 10.5 mmol) in dry DMF (20 mL). The mixture was warmed to 70 °C, stirred for 6 h at this temperature, poured into brine (40 mL), and extracted with $Et_2O$ (4 x 40 mL). The combined organic extracts were washed with water (40 mL), dried ($MgSO_4$) and evaporated. Flash chromatography of the residue over silica gel (2 x 15 cm), using 1:10 EtOAc-hexanes and then 1:5 EtOAc-hexanes, gave **19.4** (504 mg, 93%) as a colorless oil: FTIR ($CHCl_3$ cast) 1707 $cm^{-1}$; $^1H$ NMR ($CDCl_3$, 360 MHz) δ 1.29 (d, *J* = 7.3 Hz, 3 H), 2.28 (s, 3 H), 2.62-2.72 (m, 2 H), 3.32-3.40 (m, 1 H), 3.44-3.47 (m, 2 H), 3.78 (s, 3 H), 3.91 (s, 3 H), 4.90 (dq, *J* = 17.1, 1.8 Hz, 1 H),

5.00 (dq, $J$ = 10.2, 1.7 Hz, 1 H), 5.85-5.96 (m, 1 H); $^{13}C$ NMR ($CDCl_3$, 125.7 MHz) δ 12.8 (q'), 16.5 (q'), 30.5 (t'), 31.6 (t'), 42.4 (q'), 60.1 (q' or d'), 62.3 (d' or q'), 115.1 (t'), 126.8 (s'), 132.0 (s'), 136.0 (d'), 139.2 (s'), 144.6 (s'), 151.2 (s'), 152.5 (s'), 206.0 (s'); exact mass $m/z$ calcd for $C_{16}H_{20}O_3$ 260.1412, found 260.1407.

**Methyl 4,7-Dimethoxy-2,5-dimethyl-1-oxo-6-(2-propenyl)indan-2-carboxylate (19.5).**



**19.4** **19.5**

BuLi (2.5 M in hexanes, 300 μL, 0.75 mmol) was added to a stirred and cooled (-78 °C) solution of $i$-$Pr_2NH$ (115 μL, 0.82 mmol) in dry THF (1.0 mL). Stirring was continued for 30 min, and the resulting LDA solution was added dropwise by syringe over 10 min to a stirred and cooled (-78 °C) solution of indanone **19.4** (175 mg, 0.68 mmol) in THF (2.50 mL). Stirring was continued for 40 min, and the resulting enolate was quenched with neat MeOC(O)CN (82 μL, 1.02 mmol). After 1 h at -78 °C, saturated aqueous $NH_4Cl$ (10 mL) was added, and the mixture was extracted with EtOAc (3 x 25 mL). The combined organic extracts were washed with water (30 mL), dried ($MgSO_4$) and evaporated. Flash chromatography of the

residue over silica gel (1.5 x 18 cm), using 1:5 EtOAc-hexanes, gave **19.5** (173 mg, 79% or 87% corrected for recovered **19.4**, 14.0 mg) as a colorless oil: FTIR ($CDCl_3$ cast) 1745, 1707 $cm^{-1}$; $^1H$ NMR ($CDCl_3$, 400 MHz) δ 1.52 (s, 3 H), 2.30 (s, 3 H), 2.94 (d, *J* = 17.3 Hz, 1 H), 3.46-3.48 (m, 2 H), 3.64 (d, *J* = 17.3 Hz, 1 H), 3.70 (s, 3 H), 3.79 (s, 3 H), 3.91 (s, 3 H), 4.89-4.92 (m, 1 H), 5.01-5.05 (m, 1 H), 5.86-5.96 (m, 1 H); $^{13}C$ NMR ($CDCl_3$, 125.7 MHz) δ 12.8 (q'), 21.2 (q'), 30.6 (t'), 36.6 (t'), 52.6 (q'), 56.4 (s'), 60.2 (q'), 62.3 (q'), 115.3 (t'), 125.1 (s'), 132.6 (s'), 135.8 (d'), 140.2 (s'), 143.6 (s'), 151.1 (s'), 153.2 (s'), 172.6 (s'), 200.0 (s'); exact mass *m/z* calcd for $C_{18}H_{22}O_5$ 318.1467, found 318.1466.

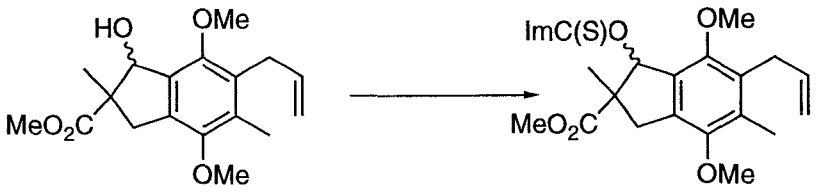
**Methyl 1-Hydroxy-4,7-dimethoxy-2,5-dimethyl-6-(2-propenyl)indan-2-carboxylate (19.6).**

**19.5** **19.6**

$NaBH_4$ (65 mg, 1.64 mmol) was added in small portions over 30 min to a stirred and cooled (0 °C) solution of ketone **19.5** (173 mg, 0.546 mmol) in dry MeOH (6.0 mL). After 40 min, water (1 mL) was added, stirring was continued for 0.5 h at 0 °C, and the resulting mixture was extracted with EtOAc

(4 x 20 mL). The combined organic extracts were dried ($MgSO_4$) and evaporated. Flash chromatography of the residue over silica gel (1.5 x 15 cm), using 1:5 EtOAc-hexanes, and then 1:14:85 MeOH-EtOAc-hexanes, gave alcohols **19.6** (159 mg, 91%) as a colorless oil: FTIR ($CDCl_3$, cast) 3459, 1730 $cm^{-1}$; $^1H$ NMR ($CDCl_3$, 360 MHz) (mixture of diastereoisomers) δ 1.26 (s, 0.68 H), 1.35 (s, 2.29 H), 1.60 (br s, 0.24 H), 2.17 (s, 2.28 H), 2.19 (s, 0.68 H), 2.64 (br s, 0.64 H), 2.80 (d, $J$ = 16.0 Hz, 0.42 H), 2.91 (d, $J$ = 15.9 Hz, 0.78 H), 3.31-3.53 [m containing d at δ 3.35 ($J$ = 15.8 Hz), 2.81 H in all], 3.64-3.74 [overlapping signals: d at δ 3.66 ($J$ = 16.1 Hz) and singlets at δ 3.70, δ 3.73 and δ 3.74, 5.62 H in all), 3.80-3.81 (two overlapping singlets, 3 H in all], 3.88 (s, 0.67 H), 4.89-4.92 (m, 1 H), 4.99-5.02 (m, 1 H), 5.08 (s, 0.21 H), 5.63 (s, 0.75 H), 5.87-5.98 (m, 0.95 H); $^{13}C$ NMR ($CDCl_3$, 125.7 MHz) (mixture of diastereoisomers) δ 12.1 (q'), 18.4 (q'), 23.5 (q'), 30.9 (t'), 31.1 (t'), 37.1 (t'), 38.7 (t'), 52.2 (q'), 52.3 (q'), 55.3 (s'), 60.0 (q'), 61.4 (q'), 62.6 (q'), 78.2 (d'), 79.8 (d'), 114.9 (d'), 115.0 (d'), 131.0 (s'), 131.1 (s'), 131.2 (s'), 131.4 (s'), 132.0 (s'), 132.1 (s'), 132.4 (s'), 133.0 (s'), 136.25 (d'), 136.30 (d'), 150.86 (s'), 150.90 (s'), 150.95 (s'), 151.2 (s'), 151.3 (s'), 152.0 (s'), 176.0 (s'), 176.8 (s'); exact mass $m/z$ calcd for $C_{18}H_{24}O_5$ 320.1624, found 320.1627.

**Methyl 1-(1*H*-Imidazol-1-ylthiomethoxy)-4,7-dimethoxy-2,5-dimethyl-6-(2-propenyl)indan-2-carboxylate (19.7).**



**19.6** **19.7**

1,1'-Thiocarbonyldiimidazole (214 mg, 1.20 mmol) was added to a stirred mixture of alcohol **19.6** (127 mg, 0.40 mmol) and DMAP (5 mg, 10 mol%) in dry 1,2-dichloroethane (2.0 mL). Stirring was continued overnight by which time all **19.6** had reacted. The mixture was diluted with $CH_2Cl_2$ (15 mL), washed with water (3 x 10 mL), dried ($MgSO_4$) and evaporated. Flash chromatography of the residue over silica gel (1.5 x 20 cm), using 1:3 EtOAc-hexanes, gave imidazolide **19.7** (167 mg, 97%) as a white crystalline solid: mp 127-136 °C; FTIR ($CDCl_3$ cast) 1732, 1694 $cm^{-1}$; $^1H$ NMR ($CDCl_3$, 360 MHz) (mixture of diastereoisomers) δ 1.51 (s, 0.76 H), 1.56 (s, 2.32 H), 2.17 (s, 2.29 H), 2.19 (s, 0.76 H), 2.84-2.92 [overlapping doublets at δ 2.87 ($J$ = 16.2 Hz) and δ 2.89 ($J$ = 16.5 Hz), 1 H in all], 3.19-3.54 (m, 2 H), 3.60-3.65 (m, 1.73 H), 3.71-3.79 [overlapping signals: singlets at δ 3.71, δ 3.72 and δ 3.79 and d at δ 3.76 ($J$ = 17.3 Hz), 8.5 H in all], 4.88-4.93 (m, 1 H), 5.00-5.02 (m, 1 H), 5.37 (s, 0.20 H), 5.84-5.95 (m, 1 H), 5.99 (s, 0.70 H), 7.08-7.09 [overlapping doublets at δ 7.08

($J$ = 1.4 Hz) and δ 7.09 ($J$ = 1.0 Hz), 0.92 H in all], 7.44 (s, 0.21 H), 7.48 (s, 0.68 H), 8.18 (s, 0.20 H), 8.21 (s, 0.70 H); $^{13}C$ NMR ($CDCl_3$, 125.7 MHz) (mixture of diastereoisomers) δ 12.2 (q'), 20.7 (q'), 25.0 (q'), 31.1 (t'), 38.4 (t'), 39.6 (t'), 52.0 (q'), 52.8 (q'), 54.9 (q'), 55.5 (q'), 55.6 (s'), 56.3 (s'), 60.10 (q'), 60.13 (d'), 61.7 (q'), 61.9 (d'), 115.2 (t'), 115.9 (d'), 129.0 (s'), 129.6 (s'), 130.8 (d'), 131.9 (s'), 132.0 (s'), 132.2 (s'), 132.6 (s'), 132.8 (s'), 133.0 (s'), 135.9 (d'), 150.6 (s'), 150.9 (s'), 151.4 (s'), 164.6 (s'), 165.3 (s')k, 173.9 (s'), 175.7 (s'); exact mass (HR electrospray) $m/z$ calcd for $C_{22}H_{26}N_2NaO_5S$ 453.1460, found 453.1460.

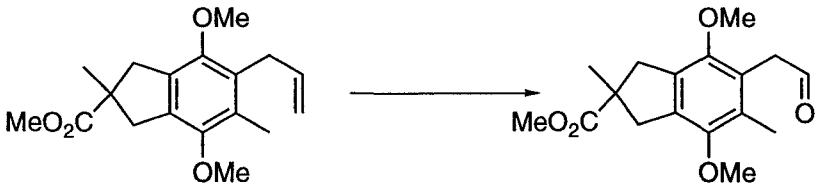
**Methyl 4,7-Dimethoxy-2,5-dimethyl-6-(2-propenyl)-indan-2-carboxylate (19.8).**

**19.7** **19.8**

A mixture of imidazolide **19.7** (173 mg, 0.402 mmol), $Bu_3SnH$ (220 μL, 0.804 mmol) and AIBN (10 mg, 15 mol%) in dry PhMe (5.0 mL) was refluxed for 1.5 h. The solvent was evaporated and flash chromatography of the residue over silica gel (1.5 x 18 cm), using 1:5 EtOAc-hexanes, gave **19.8** as a colorless oil contaminated with tin residues. Flash

chromatography over silica gel, using 1:5 EtOAc-hexanes, gave **19.8** (101 mg, 83%) as a pure, colorless oil: FTIR ($CHCl_3$ cast) 1733 $cm^{-1}$; $^1H$ NMR ($CDCl_3$, 360 MHz) δ 1.36 (s, 3 H), 2.16 (s, 3 H), 2.88 (dd, *J* = 16.0, 2.2 Hz, 2 H), 3.38-3.50 [m containing dd at δ 3.46 (*J* = 15.8, 4.7 Hz), 4 H in all], 3.70 (s, 3 H), 3.72 (s, 3 H), 3.73 (s, 3 H), 4.89-4.93 (m, 1 H), 4.98-5.02 (m, 1 H), 5.89-5.97 (m, 1 H); $^{13}C$ NMR ($CDCl_3$, 50.3 MHz) δ 11.8 (q'), 25.2 (q'), 31.0 (t'), 41.2 (t'), 41.4 (t'), 50.0 (s'), 52.1 (q'), 59.9 (q'), 60.4 (q'), 114.7 (t'), 129.1 (s'), 130.3 (s'), 131.4 (s'), 132.5 (s'), 136.7 (d'), 151.0 (s'), 177.9 (s'), two signals overlap in this spectrum; exact mass *m/z* calcd for $C_{18}H_{24}O_4$ 304.1675, found 304.1679.

**Methyl 4,7-Dimethoxy-2,5-dimethyl-6-(2-oxoethyl)-indan-2-carboxylate (19.9).**



**19.8** **19.9**

$Li_3PO_4$ buffer (pH 7.0) was prepared from 0.2 M $H_3PO_4$ and sufficient solid $LiOH.H_2O$ to bring the pH to 7.0 (pH meter).

A solution of $LiIO_4$ and $Li_3PO_4$ at pH 6.6 was then made by dissolving $HIO_4$ (2.279 g, 10.0 mmol) in the pH 7.0 $Li_3PO_4$ buffer (50.0 mL), and adjusting the resulting solution to pH 6.6 with $LiOH.H_2O$.

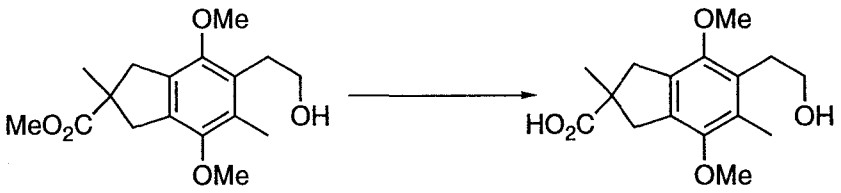
Aqueous $OsO_4$ (1.0 w/v%, 40 μL, 0.002 mmol) and the $LiIO_4$-$Li_3PO_4$ solution (0.79 mL) were added to a stirred solution of olefin **19.8** (10.5 mg, 0.035 mmol) in EtOAc (0.79 mL). Stirring was continued for 17 h ($N_2$ atmosphere). The mixture was diluted with EtOAc (15 mL), washed with water (3 x 5 mL) and brine (5 mL), dried ($MgSO_4$), and evaporated to give crude aldehyde **19.9** (10.4 mg, 98%) as a pale brown liquid (we assume the color is due to traces of osmium species): FTIR ($CDCl_3$ cast) 1727 $cm^{-1}$; $^1H$ NMR ($CDCl_3$, 360 MHz) δ 1.37 (s, 3 H), 2.12 (s, 3 H), 2.89 (d, *J* = 15.9 Hz, 1 H), 2.91 (d, *J* = 15.9 Hz, 1 H), 3.47 (d, *J* = 15.8 Hz, 1 H), 3.50 (d, *J* = 15.8 Hz, 1 H), 3.71 (overlapping singlets, 6 H in all), 3.72 (t, *J* = 2.0 Hz, 2 H), 3.74 (s, 3 H), 9.68 (t, *J* = 2.0 Hz, 1 H); $^{13}C$ NMR ($CDCl_3$, 125.7 MHz) δ 12.6 (q'), 25.1 (q'), 30.9 (q'), 41.2 (t'), 41.6 (t'), 42.5 (t'), 50.1 (s'), 52.2 (q'), 60.0 (q'), 123.5 (s'), 129.5 (s'), 131.1 (s'), 134.3 (s'), 151.0 (s'), 151.2 (s'), 177.7 (s'), 199.6 (d'); exact *m/z* calcd for $C_{17}H_{22}O_5$ 306.1467, found 306.1472.

**Methyl 5-(2-Hydroxyethyl)-4,7-dimethoxy-2,6-dimethylindan-2-carboxylate (19.10).**

**19.9** **19.10**

$NaBH_4$ (4.6 mg, 0.12 mmol) was added in three equal portions, to a stirred and cooled (0 °C) solution of aldehyde **19.9** (12.4 mg, 0.041 mmol) in dry MeOH (2.0 mL). When all the starting material had reacted (ca 0.5 h, TLC control, silica, 1:3 EtOAc-hexanes), water (0.5 mL) was added, and stirring was continued for 0.5 h at 0 °C. The solvent was evaporated and the residue was taken up in EtOAc (15 mL), washed with water (3 x 10 mL) and dried ($MgSO_4$). Evaporation of the solvent and flash chromatography of the residue over silica gel, using 1:4 EtOAc-hexanes, gave alcohol **19.10** (12.1 mg, 96%) as a colorless oil: FTIR ($CDCl_3$ cast) 3427, 1731 $cm^{-1}$; $^1H$ NMR ($CDCl_3$, 360 MHz) δ 1.36 (s, 3 H) 1.90 (br s, 1 H), 2.21 (s, 3 H), 2.84-2.97 [m containing a dd at δ 2.87 ($J$ = 16.1, 3.3 Hz) and a t at δ 2.92 ($J$ = 6.8 Hz), 4 H in all), 3.44 (d, $J$ = 15.9 Hz, 1 H), 3.48 (d, $J$ = 15.8 Hz, 1 H), 3.70 (s, 3 H), 3.73-3.79 (m, containing two singlets at δ 3.73 and δ 3.76, 8 H in all); $^{13}C$ NMR ($CDCl_3$, 125.7 MHz) δ 12.2 (q'), 25.3 (q'), 30.6 (t'), 41.2 (t'), 41.6 (t'), 50.1 (s'), 52.2 (q'), 60.0 (q'), 60.1 (q'), 62.8 (t'), 128.9 (two overlapping s'), 131.0 (s'), 132.9 (s'), 150.98 (s'), 151.09 (s'), 177.6 (s'); exact mass $m/z$ calcd for $C_{17}H_{24}O_5$ 308.1624, found 308.1619.

**5-(2-Hydroxyethyl)-4,7-dimethoxy-2,6-dimethyl-indan-2-carboxylic Acid (14.6).**



**19.10** **14.6**

$LiOH \cdot H_2O$ (23.1 mg, 0.55 mmol) was added to a stirred solution of ester **19.10** (11.3 mg, 0.037 mmol) in 1:1 dioxane-water (2 mL). After 3 h, the mixture was washed with $CH_2Cl_2$ (5.0 mL), acidified with concentrated hydrochloric acid, and extracted with EtOAc (3 x 20 mL). The combined organic extracts were dried ($MgSO_4$) and evaporated. Flash chromatography of the residue over silica gel (0.8 x 15 cm), using 1:19 MeOH-$CH_2Cl_2$, gave **14.6** (10.1 mg, 93%) as a white solid, identical to material made by our previous[22] route.

# CHAPTER 3

# SYNTHESIS OF DERIVATIZED AMINO ACIDS FOR PROTEIN SYNTHESIS BY NATIVE CHEMICAL LIGATION

## Notation and abbreviations

In the following review, structures of the type HLSSMERVEWLRKKLQDVHNF are normally written as $H_2N$-HLSSMERVEW-LRKKLQDVHNF-OH, although in the protein literature it is usual to omit the "$H_2N$-" and "-OH" at the amino and carboxyl termini, respectively.

Formulas of the type $H_2N$-SKAL$^{\alpha}$COSH, $H_2N$-SKAL-COSH, or $H_2N$-SKAL-SH should be taken to mean that the carboxyl terminus (in this case, leucine) has its carboxyl in the form of a thioacid. The usual formulation in the protein literature would be SKAL-SH, and we have used this notation sometimes.

Both three-letter and one-letter symbols for the amino acids are used, the latter especially for long sequences. For selenocysteine the abbreviations are "Sec" and "U".

The symbols $A_1...A_n$ refer to amino acid residues numbered 1 to n, and the designation $A_1...A_n$-$CO_2H$ indicates a free carboxyl on residue n. Likewise, the designation $P_1P_2...P_n$ refers to peptide segments numbered 1 to n.

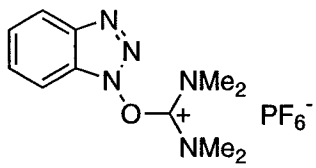
**Abbreviations**

Acm = acetamidomethyl = $CH_2NHCOMe$ (used as a sulfur protecting group: $SCH_2NHCOMe$)

Dnp = 2,4-dinitrophenyl = protection for histidine

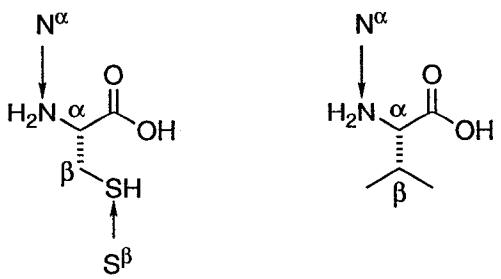
BOP = benzotriazol-1-yloxytris(dimethylamino)phosphonium hexafluorophosphate

HBTU = 2-(1*H*-benzotriazol-1-yl)-1,1,3,3-tetramethyluronium hexafluorophosphate (Note that the so-called uronium salt is, in fact, a guanidinium *N*-oxide (see Fluka *Peptide and Peptidomimetic Synthesis*; Fluka Chemie Gmbh: Buchs, 2000, page 80).

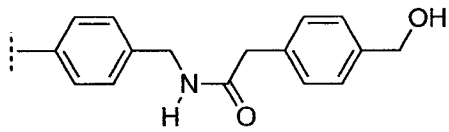


Msc = 2-(methylsulfonyl)ethoxycarbonyl = $MeSO_2CH_2CH_2OCO$-; protection for $N^{\alpha}$

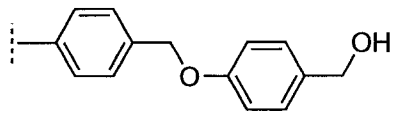
Amino acids labels are assigned according to the following system:



PAM resin:



WANG resin:



**Introduction**

Attempts to synthesize very large peptides of any sequence and of lengths up to those characteristic of proteins is an important endeavor because the development of practical methods for this purpose would have significant consequences. One can predict that the relationships between sequence and function could be identified so that artificial enzymes could be made to perform specific chemical operations. The availability of such enzymes would certainly change current industrial practice.

A great deal of work has been done in the area of large peptide synthesis.[1] With solid phase methods, peptides up to about 70 residues (statements in the literature vary from ca 50 to ca 100) in length can be assembled, but larger peptides (especially, over 100 residues[2]) are not available[3,4] because of the increasing proportions of impurities resulting from incomplete acylation at each of the individual steps. Assembly of large peptides by *simple coupling* of two shorter peptides is also not a generally practical approach, since the required activation of the carboxy terminus (for reaction with the amino terminus of the second peptide) causes epimerization at the adjacent asymmetric center, unless[5,6] the carboxyl terminus is Gly or Pro. Recently, coupling conditions proceeding with low *C*-terminal epimerization have been identified for coupling of peptide segments of up to 21 amino acid units.[7] The helpful effect of substituting the *C*-terminal backbone amide nitrogen has also been investigated

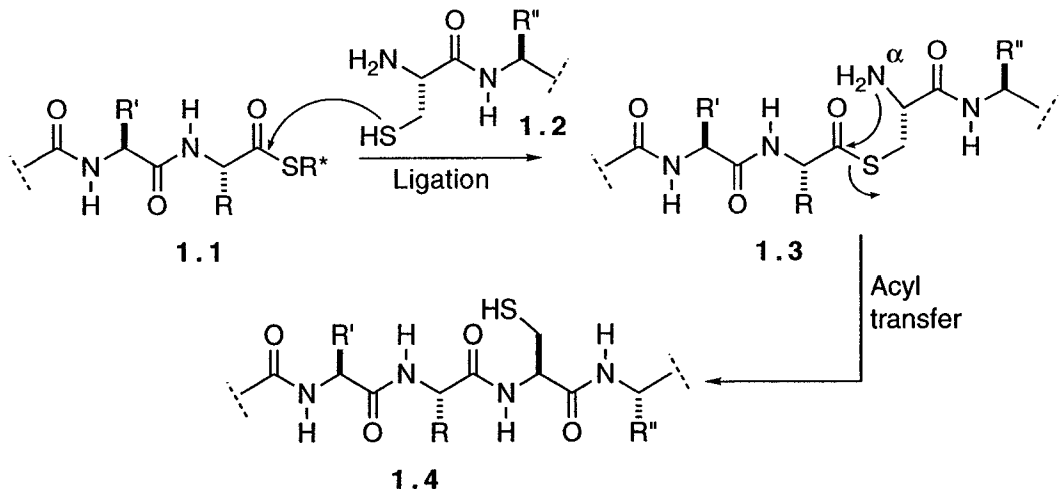
(see later in the section on *Use of amide nitrogen backbone protection*). Such protection improves yields in coupling single amino acids to build up certain sequences that otherwise give poor yields, and can also be used in coupling of protected segments, because *N*-substitution also suppress epimerization of a *C*-terminal amino acid when it is activated. However, it appears that this approach has not yet been adequately tested with large peptides.

In recent years much progress has been made to solve the problems of assembling very large peptides. These methods rely on an initial reaction that proceeds well under conditions of low concentration and that serves to link two peptides together. This ligation step is then followed by an acyl transfer that forms the peptide bond. The subject has been reviewed at length by D. Coltart[8] while he worked in this laboratory on the problem of peptide ligation, and only the currently most promising methods are described here. A number of methods for joining two large peptides together, followed by formation of a peptide bond, have been developed, but only a few of them lead to a native peptide – the others result in the formation of an unnatural unit at the site of ligation,[8] and are not dealt with in this summary.

**Native chemical ligation**

The most promising technique for linking large peptides is the process of *native chemical ligation*.[9] This was reported in 1994 (Scheme 1) by Dawson, Muir, Clark-Lewis, and

Kent,[10] and is based on the following principle:[11] An unprotected peptide α-thioester (**1.1**) is treated with an



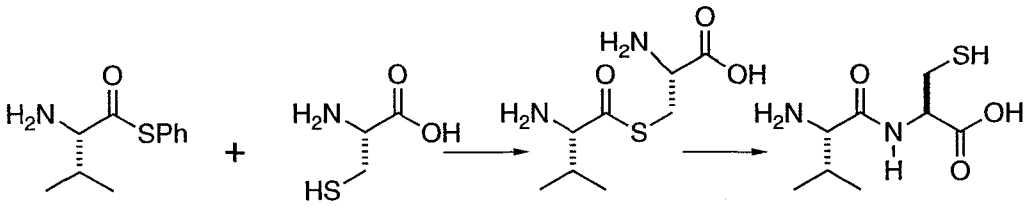
**Scheme 1**

unprotected peptide whose amino terminus is a Cys residue. Ligation occurs by thioester exchange (**1.1** + **1.2** → **1.3**), and this step, which produces a thioester-linked intermediate (**1.3**), is followed by spontaneous acyl migration (**1.3** → **1.4**). The result is that the two initial peptide segments have been joined to afford a much larger peptide with a native backbone.

A related acyl transfer is actually used in nature for the process of protein splicing, which involves the self-catalyzed excision of an intervening polypeptide – the intein – from an inactive enzyme precursor, and the formation of an active enzyme by joining the flanking regions by a peptide bond.[12]

The process summarized in Scheme 1 has a number of characteristics. Unprotected peptides are used, thus

circumventing the complications inherent in the classical use of combinations of protecting groups that lead to limited solubility of many intermediates. The initial ligation is based on the fact that thiols react readily with thioesters, even under conditions of low dilution.[13] The reaction is chemoselective so that unprotected peptides can be used, as the side-chain functional groups do not interfere. In practice, the reaction is usually run in the presence of an excess of the thiol corresponding to the thioester leaving group (or in the presence of PhSH) so as to keep Cys residues in the reduced (i.e. SH) form without interfering with the ligation. Even internal Cys residues may be present;[14] they can undergo ester exchange with the peptide α-thioester component, but this reaction is unproductive because no rearrangement to the peptide bond can occur. Formation of the thus-formed thioester is easily reversed so that reactions at internal Cys have no permanent effect on the outcome. The $S \rightarrow N$ acyl migration occurs spontaneously, and the intermediate **1.3** is usually not observed. The facility of this rearrangement results from the favorable geometric arrangement of the $N^{\alpha}$-moiety with respect to the thioester unit in **1.3**. Such "entropy activation", as it is called, was first suggested by Brenner.[15] In addition, thiol esters show a special reactivity towards amine nucleophiles.[16] The high intramolecular acylating power of the thioester functionality was first observed by Wieland,[17] who treated **2.1** with Cys (**2.2**) and obtained **2.4** (Scheme 2).



**2.1** **2.2** **2.3** **2.4**

**Scheme 2**

The thioester terminus of the *N*-terminal peptide (**1.1**) is not very highly activated, and so epimerization does not occur. In a test[2] with model peptides, using ligation at a Leu-Cys site, the presence of D-Leu in the ligation product was not detectable and was judged to be less than 1%. Racemization at a His-Cys ligation site was reported to be less than 2% in another publication.[18]

The method of native chemical ligation[10] does requires that ligation be at a Cys residue; this is a significant limitation, as Cys is not common in proteins.[19] Best results are obtained if the thioester terminus is unhindered, i.e. a non-β-branched amino acid is preferred. However, for coupling between a thioester terminus $-X^{\alpha}COSR$ and $H_2N$-$CysA_1...A_n$, amino acid X can, in fact, have any value except Pro.[20] If X = Thr,[18] Val,[18] Ile[18] or Tyr[22] ligation rates are low. For X = Cys or His, the rate is the same as for X = Gly.[18]

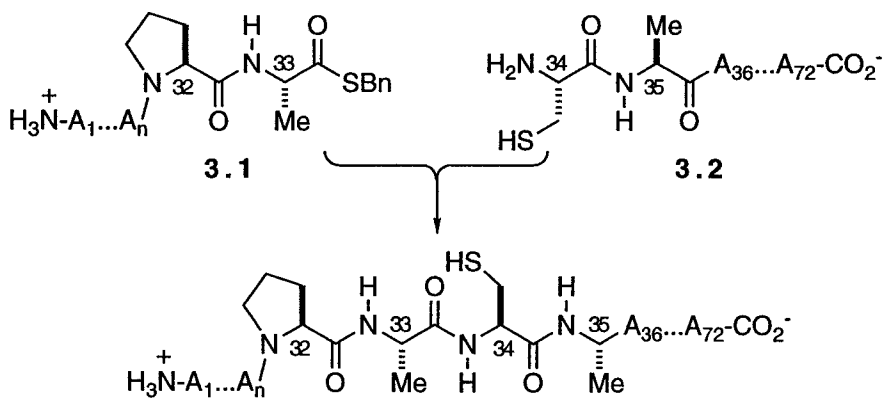
Solubilizing agents such as urea or guanidinium hydrochloride do not interfere with the ligation and rearrangement. Use of improved thioester leaving groups (i.e. variation in the nature of SR* in **1.1**) leads to faster

ligation (SPh faster than SBn).

A number of model studies, carried out by Tam and his colleagues,[23] established that very effective conditions for transthioesterification involved the addition not only of a thiol but also of a phosphine, conveniently the water-soluble phosphine $(HO_2CCH_2CH_2)_3P$, which appears to accelerate thioester exchange. In the simple cases studied [e.g. Boc-Gly$^{\alpha}$COSCH$_2$CH$_2$CO$_2$H + H$_2$N-Cys-Phe-Lys-Ala-OH] yields of the desired product Boc-Gly-Cys-Phe-Lys-Ala-OH were very high (>90%) after a reaction period of 8 h at pH 7.2. Acylation of the nitrogen was also found to be specific for the $N^{\alpha}$ amino group and the ε-*N* of lysine was not acylated.

**Synthesis of proteins and large polypeptides**

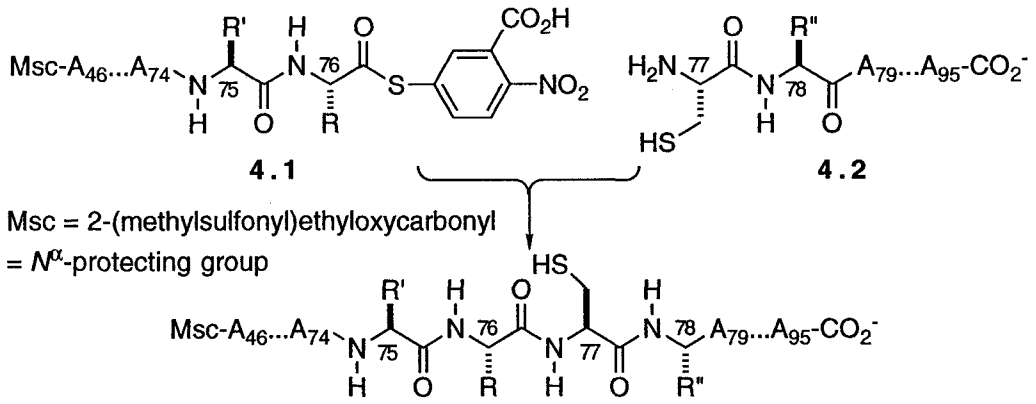
Application of the principle of native chemical ligation to the total synthesis of a protein was initially illustrated by the preparation[10] of [Ala$^{33}$]-human interleukin 8 – a 72-amino acid polypeptide mutant compound that has full biological activity.



**Scheme 3**

The two unprotected synthetic peptide segments **3.1** and **3.2**, prepared by solid phase methods, reacted cleanly in a phosphate buffer at pH 7.6 in the presence of guanidine hydrochloride and BnSH to give the full length polypeptide chain of [Ala$^{33}$]-interleukin 8 in reduced (i.e. SH) form. It is noteworthy that each of the segments contains two Cys residues, but these do not interfere with the ligation-acyl transfer.

Another peptide – residues 46-95 from the external domain of the human interleukin-3 receptor β-subunit – was also prepared, but in this case (Scheme 4) the thioester was made with a better leaving group (see **4.1**). Reaction occurred at pH 5 in an ammonium acetate buffer.

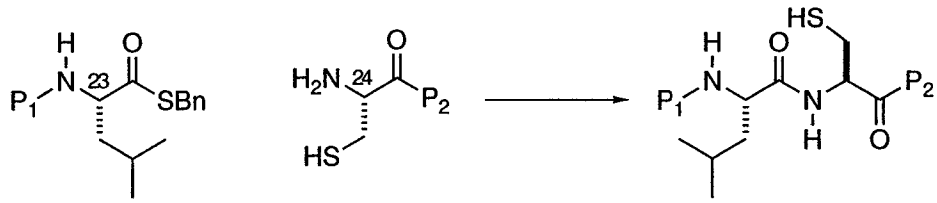


**Scheme 4**

Turkey ovomucoid third domain (OMTKY3)[24] is a potent protein inhibitor of certain serine proteinases.[2] The segment (6-56)OMTKY3[24] was synthesized by solid phase peptide synthesis, using Boc-chemistry, and by native chemical

ligation in order to compare these two different approaches.

The *C*-terminal segment (24-56)OMTKY3 has the sequence (written in the amino → carboxyl direction) $C^{24}$GSDNKTYGNKCNF-CNAVVESNGTLTLSHFGK$C^{56}$. The *N*-terminal peptide representing residues 6-23 has the sequence (also written in the amino → carboxyl direction) $V^{6}$DCSEYPKPACTLEYRP$L^{23}$ and was made in the form (6-23)$^{\alpha}$COSBn. Both compounds were prepared by solid phase peptide synthesis, the benzyl ester being generated by alkylation of the corresponding thioacid with BnBr. Ligation under standard conditions [6 M guanidinium hydrochloride, pH 7.5, 1% BnSH, 3% PhSH, 0.025 M in each peptide segment, 36 h] gave (6-56)OMTKY3. The above transformations are summarized in Scheme 5.



**5.1** **5.2** **5.3**

$P_1$ = $H_2N$-$V^{6}$DCSEYPKPACTLEYR$P^{22}$

$P_2$ = HN- $G^{25}$SDNKTYGNKCNFCNAVVESNGTLTLSHFGK$C^{56}$-OH

**Scheme 5**

BnSH present in the ligation reaction mixture acted as a reducing agent to prevent formation of disulfide bonds, both inter- and intramolecular. Its presence would also convert nonproductive ligated thioesters (from internal Cys) back into starting materials. In cases such as the present one, where the thioester has a bulky side chain (see **5.1**), *in situ*

transthioesterification with PhSH enhanced the ligation rate. The two chemical approaches (solid phase synthesis and native chemical ligation) gave comparable yields in this particular case, but the peptide involved is small – only 56 amino acid residues – and the ligation method is expected to show its superiority in the synthesis of larger targets.

Bovine pancreatic trypsin inhibitor – a 58 amino acid protein – was made in a similar way to OMTKY3, the segments used being $H_2N$-RPDFCLEPPYTGPCKARIIRYFYNAKAGLCQTFVYGG-$^{\alpha}COSCH_2CO_2H$ and $H_2N$-CRAKRNNFKSAEDCMRTCGGA-OH.[25]

In connection with studies of a transmembrane protein, the 19-amino acid segment $H_2N$-KKKSTWVLVGGVLAALAAY$^{\alpha}$COSR and the 47-amino acid segment $H_2N$-CLTTGSVVIVGRIILSGRPAVIPDREVLYQ-EFDEMEECASHLPYKKKK-$CONH_2$ have also been linked[22] under the standard conditions in the presence of PhSH. The reaction was slow – the thioester terminus is derived from a Tyr unit – and was only 50% complete after 90 h, at which point reaction was stopped. The yield of coupled native peptide was 40% after correction for recovered starting peptides, which could be reused.

A modified version of chymotrypsin inhibitor 2, a 64-amino acid protein, was prepared in like manner from (1-40)$^{\alpha}$COSR and $H_2N$-Cys(41-64) segments.[21]

Peptide synthesis with the phosphine-thiol method[23,26] was used to make a number of peptides ranging from 9 to 54 amino acid residues (Scheme 6[23]). Again, unprotected internal Cys does not interfere with the ligation-acyl transfer

| | Thioester | *N*-Terminal cysteinyl peptide | Yield |
|---|---|---|---|
| 1 | $H_2N$-SRDFG-SR* | $H_2N$-CAKA-OH | 88% |

**Scheme 6**

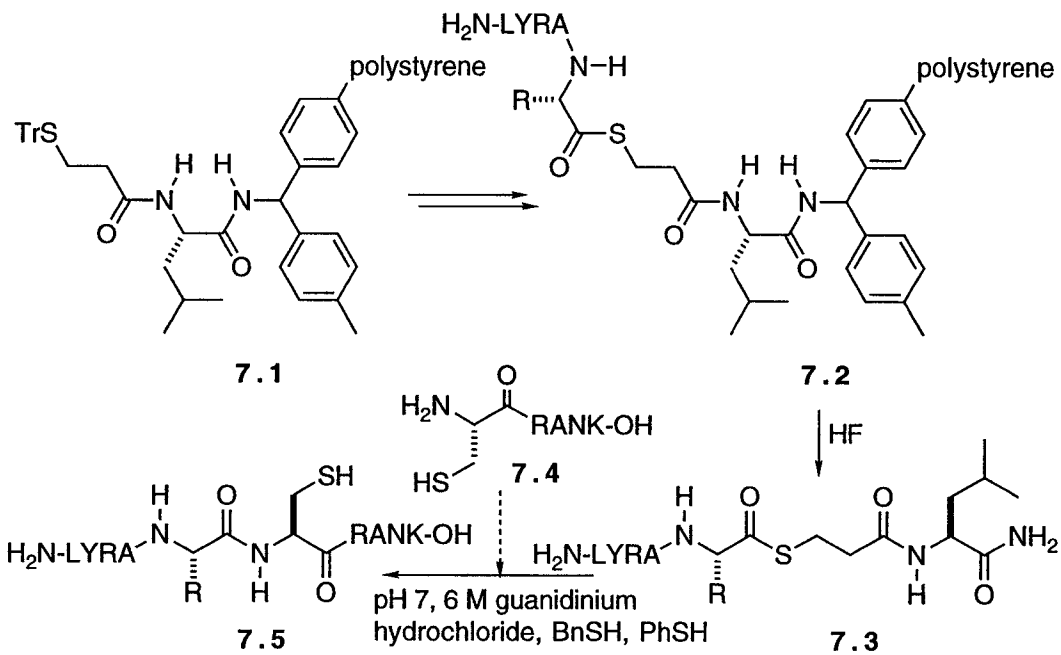
sequence (example #4).

## Control of reactivity of thioesters

The reactivity of the thioester can be altered *in situ*[11] since peptide α-thioesters undergo transthioesterification[4] when exposed to thiols. Thus, peptides containing a benzyl α-thioester can be converted into the more reactive phenyl α-thioester by addition of thiophenol to the ligation mixture.[4,11] In a test case,[4] synthetic peptides corresponding to barnase(1-48)$^{\alpha}$COSBn and the analog sequence [$Cys^{49}$,$His^{80}$,$Ala^{102}$]barnase(49-110) were ligated in the presence of either BnSH or PhSH. After 7 h the reaction involving PhSH was essentially complete, but with BnSH the process was only 25% complete. Peptides corresponding to barnase(1-48)$^{\alpha}$COSBn and the analog sequence [$Cys^{49}$]barnase(49-110) were also ligated in the presence of PhSH.[4] Formation of [$Cys^{49}$]barnase was essentially complete after 4.5 h at pH 7.5.

**Preparation of thioesters and effect of varying the thioester terminus**

In order to facilitate the preparation of thioesters, a resin and linker system (see **7.1** and **7.2**) was designed that is compatible with the standard conditions used for Boc-chemistry solid phase peptide synthesis.[18] After cleavage from the resin, the resulting thioester **7.3** can be used directly for native chemical ligation (**7.3** → **7.5**). A variety of peptide thioesters $H_2N$-LYRAX$^{\alpha}$COSR, where X$^{\alpha}$COSR represents the thioester of any amino acid, were prepared and ligated with $H_2N$-CRANK-OH (**7.4**, Scheme 7) to yield $H_2N$-LYRAXCRANK-OH (**7.5**).



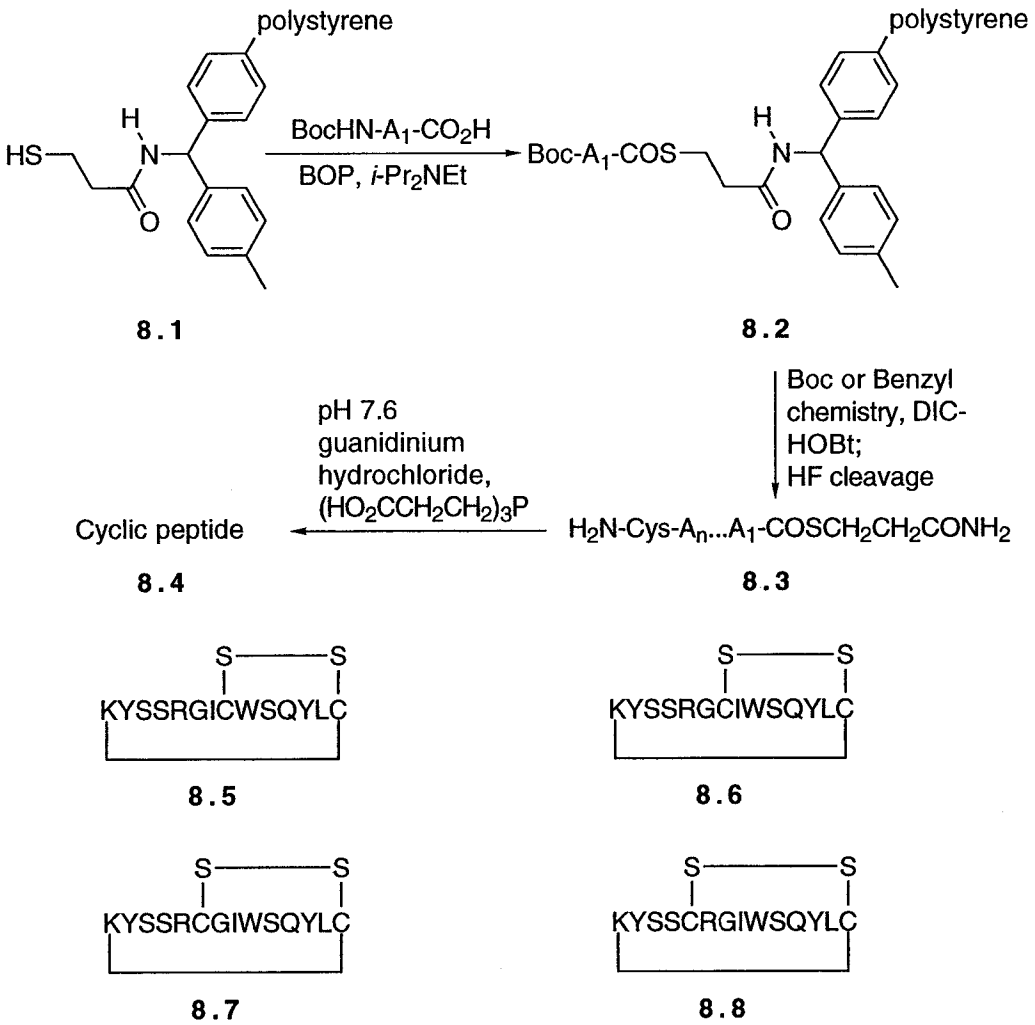
**Scheme 7**

It was found[18] that ligation occurred when X represented any of the 20 natural amino acids, although when X = Pro,

Ile, and Val ligation was slow, with the ligation-acyl transfer sequence being less than 75% complete after 48 h. Interestingly, when X = His or Cys, reaction is as fast as with Gly, the least hindered amino acid. It is possible that the side chains of His and Cys participate in catalysis of the rate-limiting step – the transthioesterification. Racemization of amino acid X at the X-Cys ligation site was examined for the case of X = His, and found to be less than 2%.[18]

The approach of Scheme 7 has been used[27] to produce cyclic peptides by native chemical ligation, as summarized in Scheme 8. Linear peptides were made by solid phase synthesis, using the resin **8.1**. After attachment of the initial amino acid, standard stepwise assembly, using Boc- and benzyl-chemistry, followed by detachment from the resin, gave the required linear peptides. When these were subjected to standard conditions for native chemical ligation, intramolecular transthioesterification occurred, and then acyl transfer produced the final cyclic peptide. While internal Cys residues also underwent transthioesterification with the *C*-terminal thioester (see **8.3**), formation of such thiolactones is reversible and they are eventually converted into the productive *N*-terminal thiolactone that undergoes the $S \rightarrow N$ acyl transfer. The initial products were oxidized to cyclic disulfides using DMSO in an aqueous buffer at pH 5-6. In this way, cyclic peptides **8.5**-**8.8** were prepared.

Cyclizations can also be effected[27] before detachment



BOP = benzotriazol-1-yloxytris(dimethylamino)phosphonium hexafluorophosphate
DIC = diisopropylcarbodiimide
HOBt = 1-hydroxybenzotriazole

**Scheme 8**

from the resin, but in this case, a different thioester linker and resin were used. After deprotection of the resin-bound peptide, intramolecular transthioesterification served to release the peptide from the resin and set the stage for acyl transfer.

The peptide $H_2N$-CGGGEYFTLQIRGRERFEMFRELNEALELKDAQAGKEP-GG-COSR, made by solid phase peptide synthesis, using Boc-

chemistry, was cyclized[28] to give a catenane; this was possible because the peptide spontaneously folds and dimerizes *faster* than ligation. In this case, of course, the Cys residue of each component of the initial dimer ligates with the thioester terminus of the other component; only in this way can a catenane be formed.

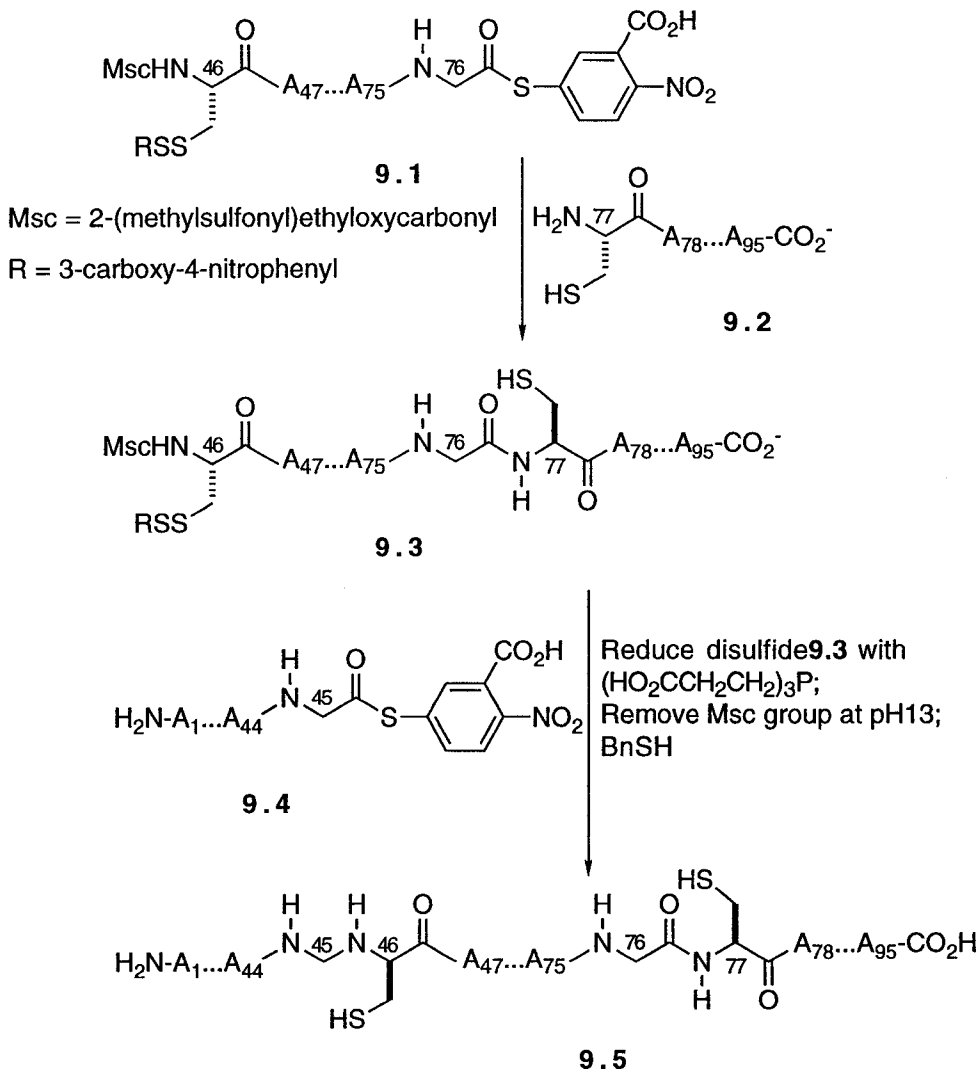
A number of other cyclic peptides[29,30,31,32] have been made by the general technique of subjecting $H_2N$-Cys-$A_1$...$A_n$-COSR to conditions for native chemical ligation.

Biosynthetic methods[33,34] have also been used to generate thioesters, but these routes are beyond the scope of this review.

**Multiple native chemical ligations and ligations on a solid phase**

Multiple native chemical ligations have been explored,[11] and in an early test of this process, an analog of a natural protein containing 95 amino acid residues was made. To accomplish this, two pairs of residues were changed from the wild type: $Ser^{45}$ and $Ser^{76}$ were both changed to Gly to improve the kinetics of the ligation steps, and $Lys^{46}$ and $Arg^{77}$ were both changed to Cys, as the presence of Cys is essential for the ligation. Three subunits **9.1**, **9.2**, and **9.4** were made by solid phase peptide synthesis.

In the first ligation and acyl transfer (**9.1** + **9.2** → **9.3**) the Cys terminus of **9.1** was protected on nitrogen by a base labile group, and the thiol was protected as a disulfide



**Scheme 9**

Hence only the desired ligation took place. In the final ligation BnSH was included in the reaction mixture to reverse unproductive reaction of the thiol of $Cys^{77}$. The successful synthesis of **9.5** suggested that multiple ligations could be used to make proteins with well in excess of 100 amino acid residues.

The 124-amino acid polypeptide chain of human secretory phospholipase $A_2$ ($hsPLA_2$) was synthesized as well as an analog

$H_2N$-$N^{1}$LVNFH(Dnp)RMIKLTTGKEAALSYGFYGCH$^{27}$(Dnp)-SR

Dnp = 2,4-dinitrophenyl

**Scheme 10**

in which $His^{47}$ was replaced by the isosteric β-thienylalanine (Bta).[18]

To make $hsPLA_2$, the four subunits **10.1-10.4** were prepared by solid phase methods using, in the case of **10.1-10.3**, the special resin (see Scheme 7) for producing thioesters. Subunits **10.3** and **10.4** were coupled and required 24 h at 37 °C for 90% ligation. After removal of the Msc group the resulting (59-124)-peptide was coupled with **10.2**, and with an analog (not show in Scheme 10) in which $His^{47}$ was replaced by $Bta^{47}$. These reactions with **10.2** involve Gly-Cys ligations and, accordingly, were complete in only 6 h. Again, after removal of the Msc group, the resulting materials were coupled with **10.1**. The reactions,

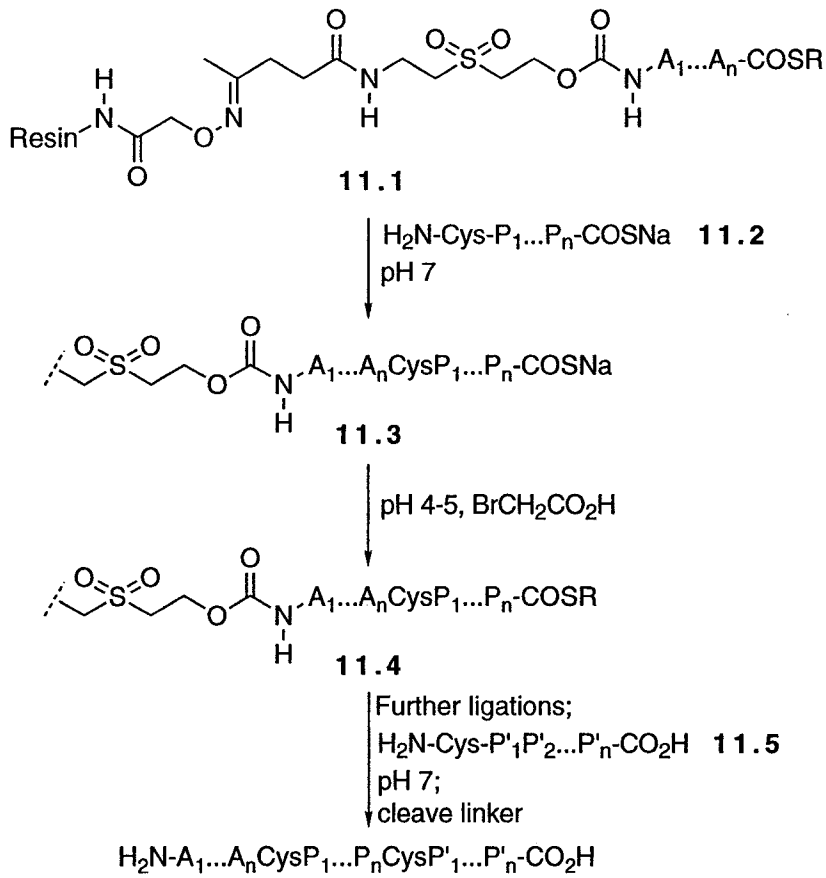
which generate a His(Dnp)-Cys ligation site were complete in 9 h. The Dnp groups were probably removed during the ligations, but this is not clearly stated in the publication.[18]

Typically, for native chemical ligation, each ligation affords the desired product in yields of 40-60% and, in order to improve the efficiency of multiple native chemical ligations by avoiding handling losses (HPLC purifications), ligations on a solid support have been studied[35,36,37] (Schemes 11[35] and 13[36]).

In one approach[35] the polypeptide can be assembled in either the *N* → *C* or the *C* → *N* direction. For *N* → *C* assembly, the middle segments were used in the form $H_2N$-Cys-(peptide)$^{\alpha}$COSNa because the thiocarboxylate – unlike the corresponding ester – is unreactive under ligation conditions so that the *N*-terminal Cys does not react with the *C*-terminal thiocarboxylate. For *C* → *N* assembly, the middle segments were used in the form $H_2N$-Cys(Acm)-(peptide)$^{\alpha}$COSR, the sulfur protecting group at the *N*-terminal Cys preventing premature ligation with the $^{\alpha}$COSR terminus. The segments were synthesized by standard, or previously-developed, methods on $^{\alpha}$COSH, $^{\alpha}$COSR, or PAM resins.

For construction in the *N* → *C* direction the *N*-terminal segment was attached to a water-compatible support (based on cellulose) by a cleavable linker (see **11.1**). The next peptide segment (**11.2**) was added under native chemical ligation conditions (pH 7, 1% PhSH). Once ligation was

complete, the pH was lowered to 4-5, and the terminal thiocarboxylate was allowed to react with $BrCH_2CO_2H$ so as to form a terminal thioester (**11.3** → **11.4**). The pH was then



**Scheme 11**

returned to 7 and the polymer-bound peptide thioester was then ready for the next ligation. This cycle was repeated and, after ligation of the final peptide segment the linker to the support was cleaved by brief treatment with NaOH, freeing the full-length peptide **11.6**.

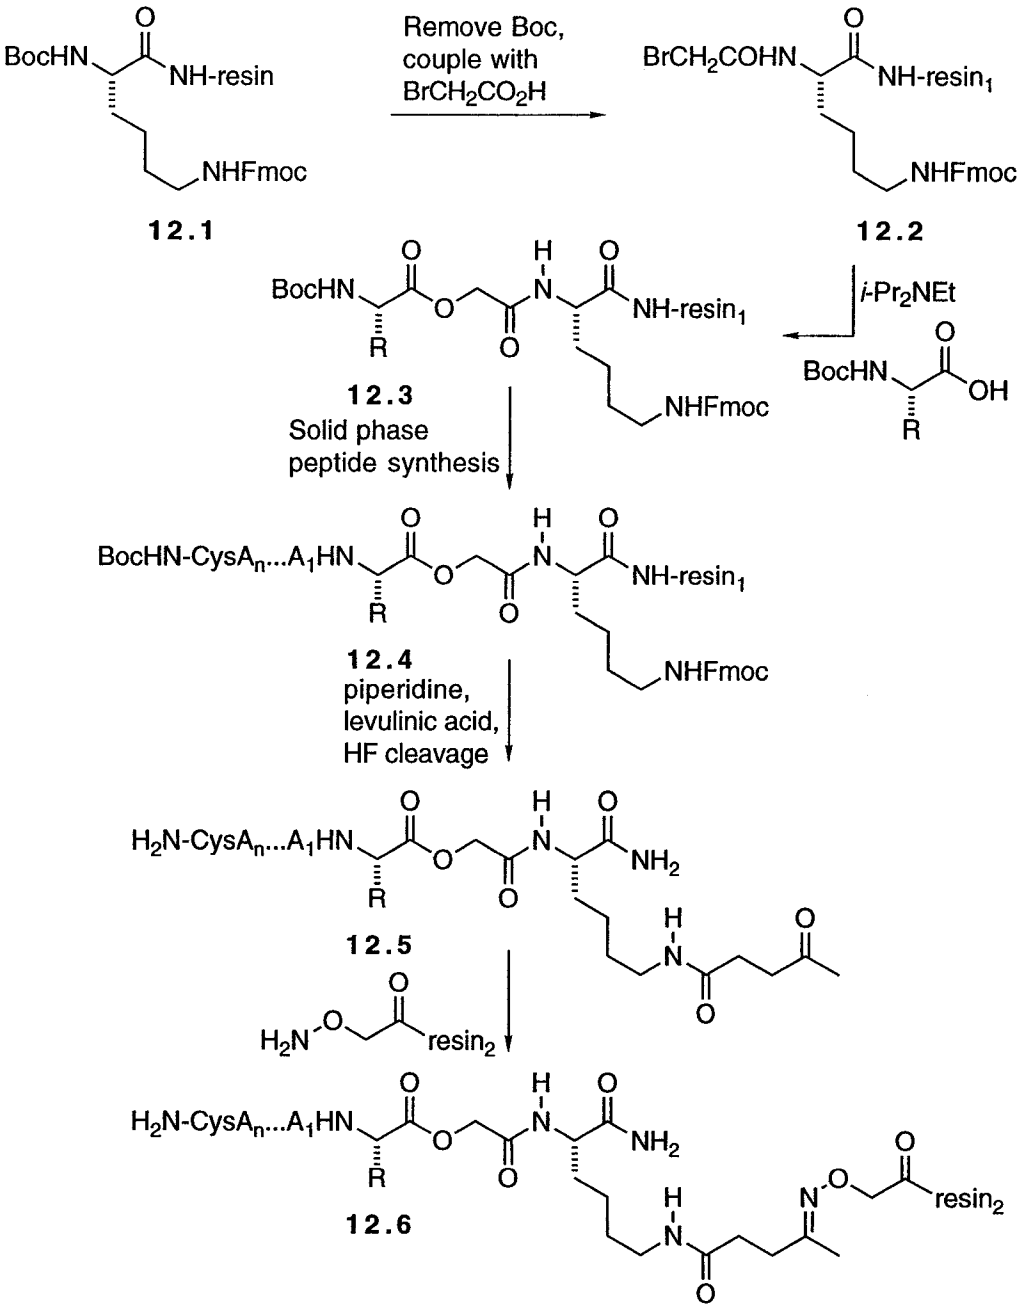
To illustrate the efficacy of the technique, several

polypeptides were made, each requiring two sequential ligation steps. First, three arbitrary peptide segments were coupled, these being $H_2N$-LTEGLHGFHVHEFGDNTAGCTSAGPHFNPL-SRKH$^{\alpha}$COSR at the *N*-terminus, $H_2N$-CGFRVREFGDNTAV$^{\alpha}$COSNa for the middle segment, and $H_2N$-CADPSEEWVQKYVSDLELSA-OH as the *C*-terminus, so as to produce a 68-residue peptide.

In the second example a 74-residue protein belonging to the human complement system[38] was made, using the three segments $H_2N$-TLQKKIEEAAKYKHSVVKK$^{\alpha}$COSR (*N*-terminus of 20 residues), $H_2N$-CCYDGACVNNDETCEQRAARISLGPK$^{\alpha}$COSNa (middle segment of 26 residues), and $H_2N$-CIKAFTECCVVASQLRANISHKDMQL-GR-OH (*C*-terminus of 28 residues). Finally, the 115-residue polypeptide of the protein macrophage migration inhibitor,[39] a mediator of inflammatory response, was constructed from the three segments $H_2N$-MPMFIVNTNVPRASVPDGFLSELTQQLAQATGKPPQYIA-VHVVPDQLMAFGGSSEPCAL$^{\alpha}$COSR (*N*-terminus of 59 residues), $H_2N$-CSLHSIGKIGGAQNRSYSKLL$^{\alpha}$COSNa (middle segment of 21 residues), and $H_2N$-CGLLAERLRISPDRVYINYYDMNAASVGWNNSTFA-OH (*C*-terminus of 35 residues).

Construction in the $C \rightarrow N$ direction is summarized in Scheme 12, where $resin_1$ is a polystyrene-based resin and $Resin_2$ is based on cellulose. The *C*-terminal peptide is built up on the first resin (Scheme 12), using the linker shown in **12.3**. This linking system, part of which is based on the carboxyamidomethyl protecting group for carboxylic acids, is compatible with Boc- and Fmoc-based solid phase peptide synthesis, and can be detached at the end of the

synthesis by mild base treatment. The linker also allows a water-compatible support to be joined (see **12.4** → **12.5** → **12.6**) to the lower Fmoc-protected arm, and the first resin can then be removed.



**Scheme 12**

The second peptide segment, bearing a protected *N*-terminal Cys and a *C*-terminal thioester, is then attached under native chemical ligation conditions (pH 7, 1% PhSH) to the first segment (i.e. to **12.6**), which is still attached to the water-compatible polymer (resin 2). The *N*-terminal Cys of each of these middle segments was protected on sulfur with an Acm group ($CH_2NHCOMe$). This group is stable to $CF_3CO_2H$, HF, nucleophiles (including thiols), and is readily removed with $Hg(OAc)_2$.

After ligation, the *N*-terminal Cys is deprotected, and the material is ready for a second ligation. This cycle is repeated and, after the final segment has been attached, the linker to the water-compatible polymer support is cleaved at pH 12-14 [to cleave the carboxyamidomethyl unit, $OCH_2C(O)NH$], releasing the unprotected polypeptide.

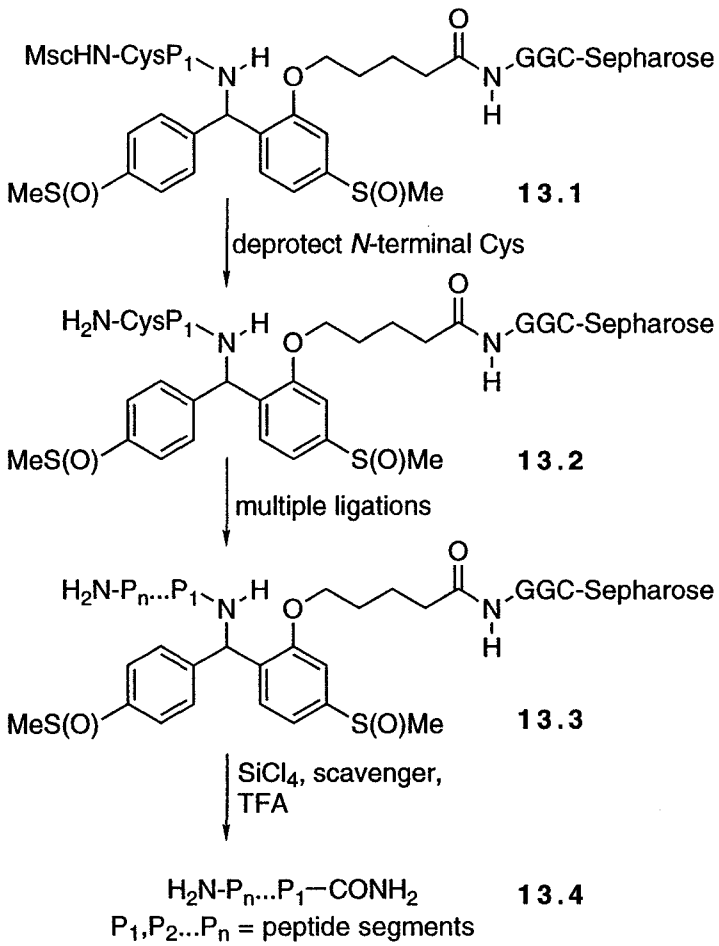
The *C* → *N* construction was tested by making the 27-residue peptide $H_2N$-ALTKYGFYGCYGRLEEKGCADRKNILA-OH from the appropriate segments $H_2N$-CADRKNILA-*O*-linker (cf. **12.4**), $H_2N$-C(Acm)YGRLEEKG$^{\alpha}$COSR, and $H_2N$-ALTKYGFYG$^{\alpha}$COSR.

The 118-residue protein human group V secretory phospholipase $A_2$ (GV-$PLA_2$)[40] was made to illustrate synthesis of a protein by solid phase *C* → *N* construction. The sequence was divided into four segments at suitably located Cys residues, using three native chemical ligations. The segments ranged in length from 25 to 33 amino acids and consisted of the sequences GV-$PLA_2$(88-118), GV-$PLA_2$(59-87), GV-$PLA_2$(26-58), and GV-$PLA_2$(1-25). All peptide solutions

ranged in concentrations from 11 to 14 mM, but evidence was obtained that using higher concentrations (27 - 50 mM, depending on the solubility of the segment) and shorter reaction times would allow the synthesis to be completed more quickly. The first ligation – that between $Leu^{87}$ and $Cys^{88}$ – was slower than the others, which were Gly-Cys ligations.

The method has been used to couple up to seven unprotected peptide segments.[41]

In related work,[36] the first peptide segment was connected to the solid support via the complicated linking

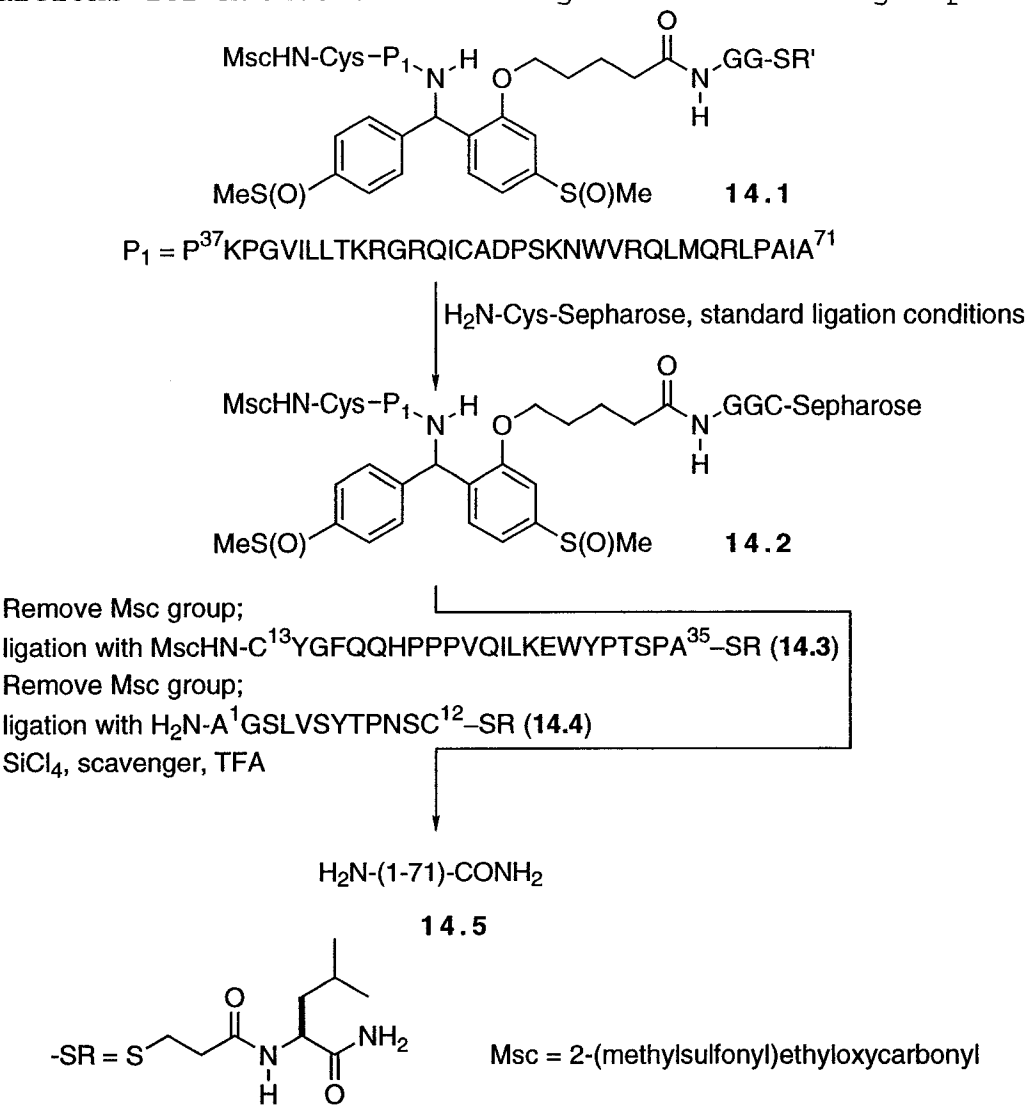


**Scheme 13**

unit shown in **13.1**. The best support was found to be Sepahrose (4% cross-linked agarose functionalized with primary amino groups). The actual attachment was by a native chemical ligation – hence the linking amino acid is a Cys residue attached to the resin (see **13.1**). The system is stable to the conditions used in Boc-chemistry and, of course, in native chemical ligation; cleavage of the final polypeptide from the linker is achieved by reduction ($SiCl_4$) of the sulfoxide groups, followed by exposure to $CF_3CO_2H$. The *N*-terminal Cys residues of all the middle segments (see Scheme 13, $P_1$, $P_2$, $P_3$...$P_{n-1}$) were protected either on *N* as 2-(methylsulfonyl)ethyloxycarbonyl derivatives [Msc] or on *S* as acetamidomethyl derivatives ($SCH_2NHCOMe$). The Msc group is removed by brief exposure to pH 13, and the Acm group by treatment with $Hg(OAc)_2$ at pH 4. The approach summarized in Scheme 13 affords a peptide with a *C*-terminal amide (see **13.4**).

In order to demonstrate the use of the solid phase method in protein synthesis a 71-amino acid chemokine [vMIP-I] was synthesized (Scheme 14).[36] This target was chosen because it contains all 20 natural amino acids. The route is summarized in Scheme 14. The *C*-terminal segment **14.1** was made on a thioester resin (see **14.1**; the group R in **14.1** was not specified in the original publication), the *N*-terminus of this segment being protected with an Msc group. This unit was attached to a Cys-Sepharose support using the standard

conditions for native chemical ligation. The Msc group was



**Scheme 14**

removed and the resulting peptide was ligated with the Msc-(13-35)COSR segment **14.3**. Finally, after deprotection of the terminal Cys, a third ligation was done with the $H_2N$-(1-12)COSR segment **14.4**. The resulting resin-bound 71-amino acid peptide was treated with $SiCl_4$ in the presence of several scavengers (thioanisole, *m*-cresol, ethanedithiol) in $CF_3CO_2H$ to release the protein **14.5**.

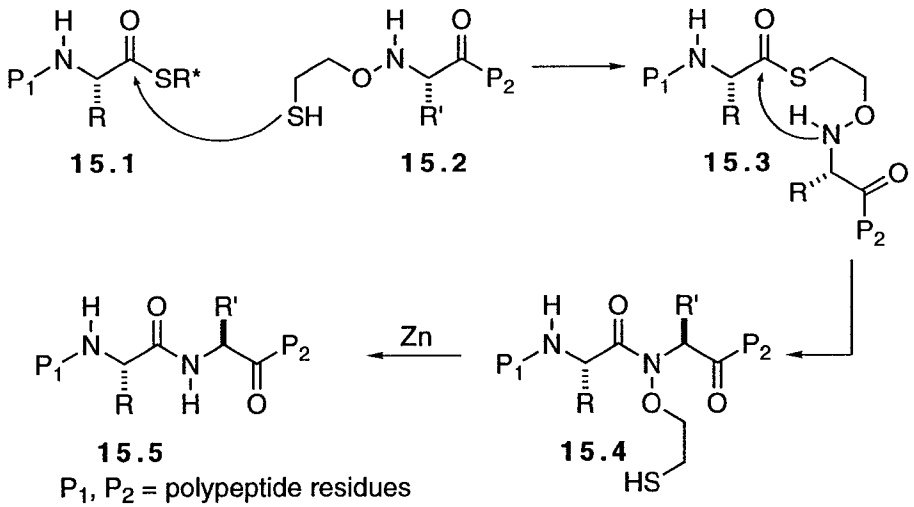
A second synthesis[36] was carried out using Cys($S^{\beta}$Acm) on the side chain thiol of the *N*-terminal Cys residues, simply to show that a choice of protection methods is available for Cys. The peptide thioesters and $H_2N$-$C^{36}$($S^{\beta}$Acm)PKPGVILLTKR-GRQICADPSKNWVRQLMQRLPAIA$^{71}$-SR, $H_2N$-$C^{13}$($S^{\beta}$Acm)YGFQQHPPPVQILKE-WYPTSPA$^{35}$-SR and $H_2N$-$A^{1}$GSLVSYTPNSC$^{12}$-SR (**14.4**) were assembled as before, except that the Acm (acetamidomethyl, $SCH_2NHCOMe$) groups were removed by treatment with $Hg(OAc)_2$ at pH 4. This procedure gave the protein **14.5** in quantitative yield and of similar purity to the synthesis using Msc protecting groups.

**Extension of the ligation site beyond cysteine**

Cys is an uncommon amino acid, comprising only 1.7% of the residues in proteins[19] (only Trp, Met, and His appear less frequently[42]) and so extension of the ligation site beyond Cys is an important aim.

*(a) Glycine left at the ligation site instead of cysteine*

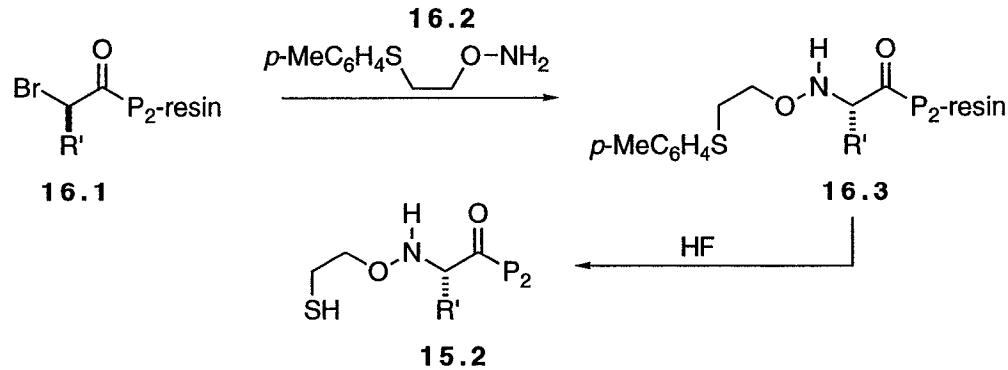
Some extension beyond Cys of the suitable residues at the ligation site was made by use of an oxyethyl linker.[43] The peptide α-thioester **15.1** reacts with the $N^{\alpha}$(oxyethanethiol) peptide **15.2** to form the ligation product **15.3**. This rearranges through a six-membered ring to the amide-linked product **15.4**. The $N^{\alpha}$(oxyethanethiol) subunit is stable to HF cleavage conditions but is removed by reduction with Zn (**15.4** → **15.5**).



**Scheme 15**

In implementing this approach[43] the peptide thioesters were generated from the corresponding thioacids, themselves made by established solid phase methods. Alkylation of the thioacids with BnBr or reaction with 5,5'-dithiobis(2-nitrobenzoic acid) gave the thioesters, both types being equally suitable for the subsequent ligation, with the benzyl thioesters reacting more slowly.

The oxyethanethiol peptides **15.2** were made by bromide



**Scheme 16**

displacement (with stereochemical inversion) along the lines summarized in Scheme 16. The starting bromo peptide **16.1** was made by acylation of the *N*-terminus using the symmetrical anhydride $(BrCHRCO)_2O$, and the halogen was then displaced with reagent **16.2**. Cleavage from the resin and deprotection, both done with HF, then gave peptide segment **15.2**.

Scheme 15 summarizes the principle of the method; a number of particular cases were examined, as summarized in Scheme 17.

| | Thioester 15.1 | Derivatized peptide 15.2 | Yield of 15.4 |
|---|---|---|---|
| 1 | $H_2N$-LYRAG-SNB | $HN^{\alpha}$(X)-GRNTATIMMQRGNFR$^{\alpha}CONH_2$ | 75% |
| 2 | $H_2N$-LYRAF-SBn | $HN^{\alpha}$(X)-GRNTATIMMQRGNFR$^{\alpha}CONH_2$ | 64% |
| 3 | $H_2N$-LYRAG-SBn | $HN^{\alpha}$(X)-AARHTVHQRHLHG-OH | 69% |
| 4 | $H_2N$-LYRAF-SBn | $HN^{\alpha}$(X)-AARHTVHQRHLHG-OH | 0% |

SNB = 3-carboxy-4-nitrophenyl thioester, X = $HSCH_2CH_2O$

**Scheme 17**

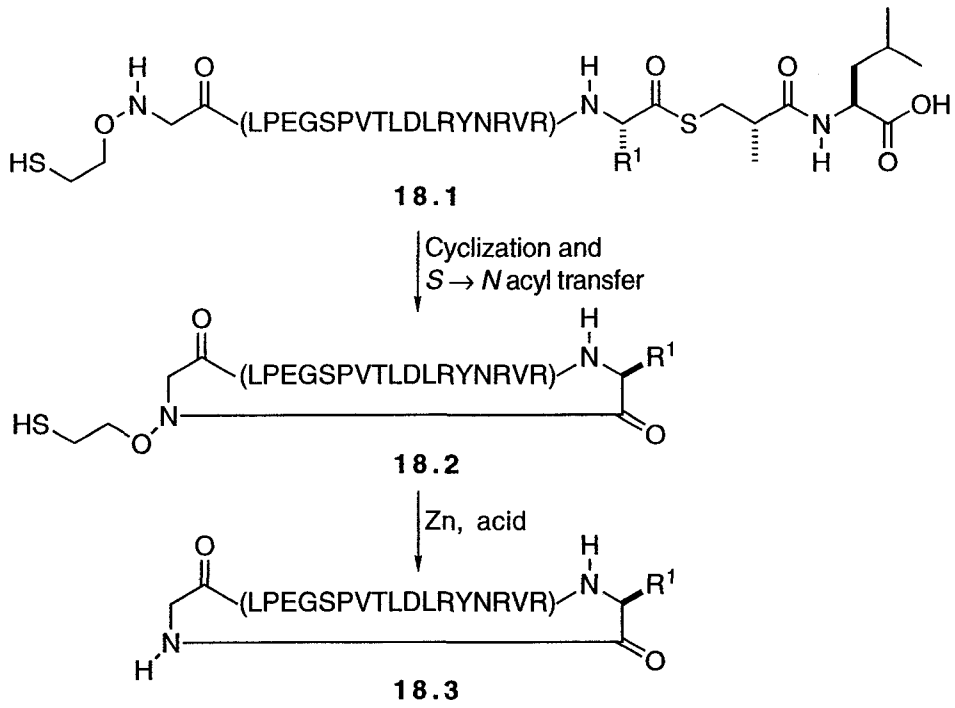
In the first ligation an overnight reaction period at 25 °C gave the rearranged product (cf. **15.4**) in 75% yield, and Zn reduction removed the auxiliary. The second ligation involves the thioester of a more hindered *C*-terminal amino acid (Phe versus Gly); reaction was slowed compared with he first ligation, but heating to 37 °C or lowering the pH to 4 after the initial ligation accelerated the acyl transfer. The rearrangement (cf. **15.3** → **15.4**) was also retarded, and the intermediate corresponding to **15.3** could be isolated. After 10 h at 37 °C at pH 4.5 rearrangement of the initial ligation product was complete.

Ligation #3 served to reveal the influence of steric hindrance adjacent to the *N*-modified amino acid **15.2** (Ala versus Gly). The rate was similar to that of ligation #2, and was also enhanced by heating at 37 °C. Again the initial ligation product could be isolated, but its rearrangement was not accelerated by lowering the pH to 4.5. After 2 days at 37 °C rearrangement was complete.

When sterically hindered amino acids are present on both sides of the intended ligation site – Phe versus Gly at the thioester terminus and Ala versus Gly adjacent to the *N*-modified amino acid – as in the last example, the initial ligation did occur, but there was no evidence for the rearrangement (cf. **15.3** → **15.4**). Evidently, the presence of side chains on both sides of the ligation site provided too much steric hindrance for rearrangement via a six-membered intermediate.

These results suggest that the method will prove suitable for ligations in which one of the amino acids flanking the ligation site is Gly, and this amino acid can be part of the thioester unit **15.1** or the other segment **15.2**; β-branched amino acids in both **15.1** and **15.2** cause the method to fail. The rearrangement in the present approach involves a six-membered transition state, and was found to be appreciably slower than the corresponding rearrangement of the original native chemical ligation, which involves a five-membered transition state.

The procedure has also been applied to the synthesis of



**18.1**

**18.2**

**18.3**

**Scheme 18**

cyclic peptides (Scheme 18).[44]

The linear peptides **18.1** ($R^1$ = H, Me, $PhCH_2$) were prepared, using established methods,[43] and subjected to conditions for ligation and acyl transfer (6M guanidine hydrochloride, pH 7.5 buffer, PhSH). Reduction of the resulting cyclized products **18.2** served to remove the $HSCH_2CH_2O$-group and gave the desired cyclic peptides **18.3** with a native backbone structure.

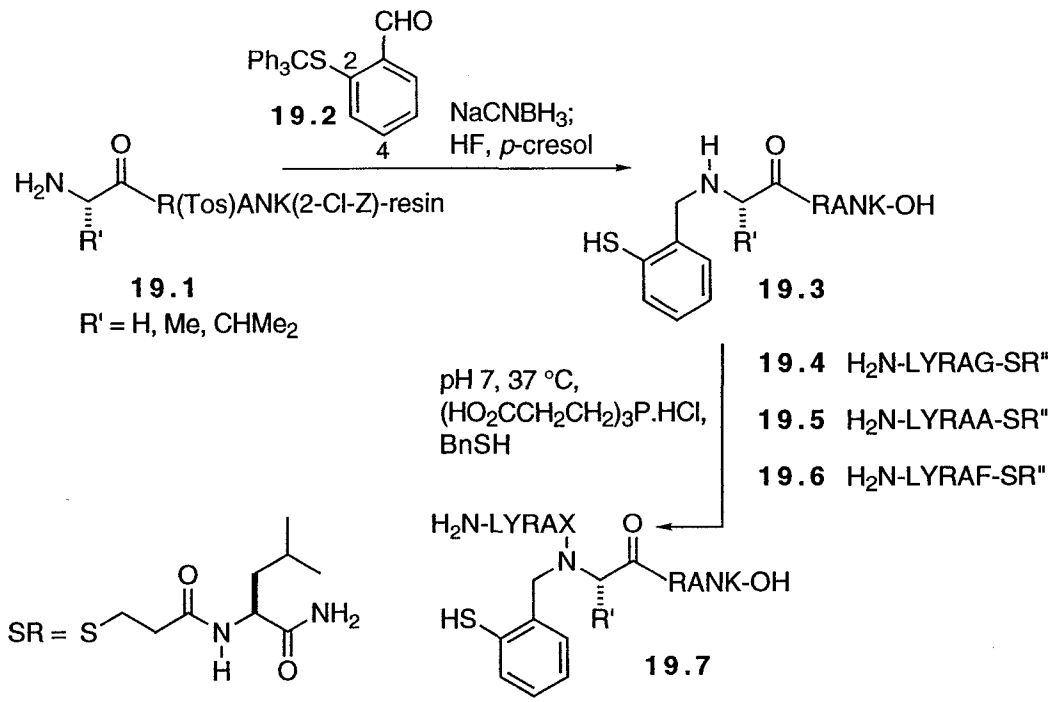
The rate of ligation depended on the nature of the amino acid residues being linked: for a Gly-Gly ligation (**18.1**, $R^1$ = H) the process was complete in 16 h. For Gly-Ala (**18.1**, $R^1$ = Me) and Gly-Phe (**18.1**, $R^1$ = $CH_2Ph$) ligations two products – presumed to correspond to the amide and the intermediate thioester – were detected after 12 h. Only lowering the pH

from 7.5 to 4.5 was effective in driving the reaction to completion (in 48 h).

For **18.1** ($R^1$ = $PhCH_2$) no detectable (i.e. <5%) racemization was observed. This was established by using also D-Phe in the synthesis and examining the product from the natural series for the presence of cyclic peptide containing the unnatural phenylalanine diastereoisomer.

*(b) Attempts to develop a general auxiliary that allows any amino acid at the ligation site*[45]

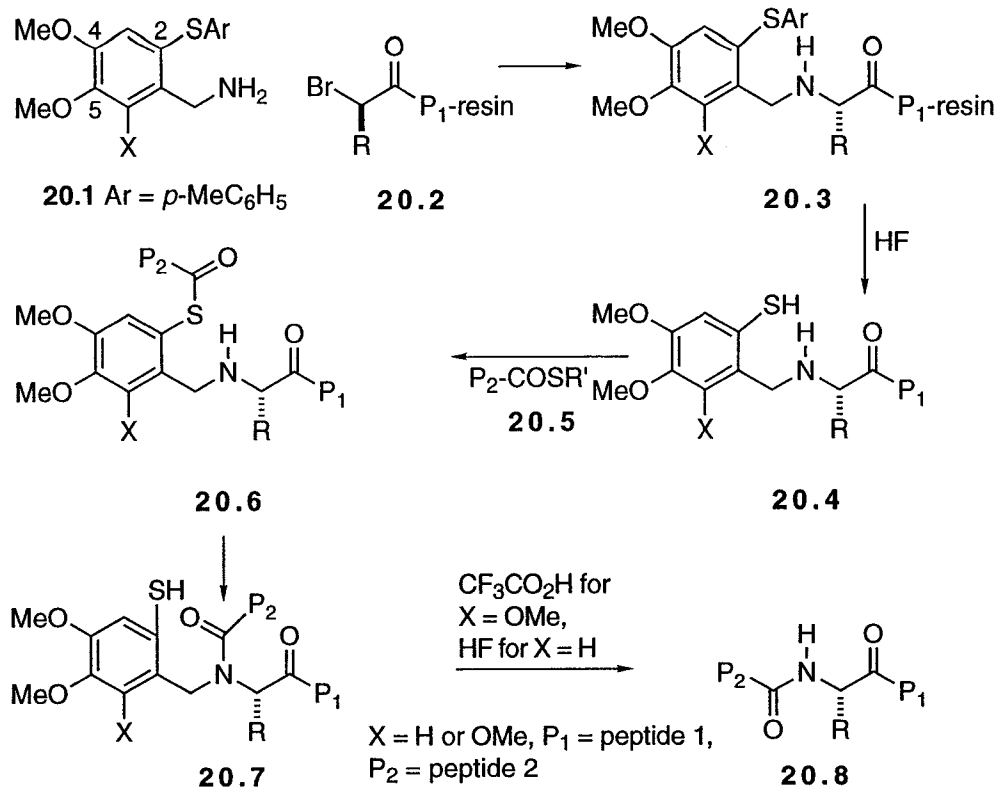
The resin bound protected peptide **19.1** was treated with aldehyde **19.2**, and the resulting imine was reduced. Cleavage from the resin gave pentapeptide **19.3**. The value of R' was varied (R' = H, Me, $CHMe_2$) in different experiments, and the individual pentapeptides **19.3** were then ligated with (depending on the case) **19.4**, **19.5**, or **19.6**. Half-lives were measured for production of the decapeptides **19.7**, and varied from 0.5 h to 48 h. In the case of **19.3** (R' = $CHMe_2$) ligation with **19.4** (other thioesters were not tested) reaction was less than 5% complete after 24 h. The experiments established that ligations involving Gly at either side of the ligation site go to completion in under 24 h, provided β-branched amino acids (e.g. Val) or proline are absent from the other side. In this work the auxiliary was not removed from the coupled peptide. When a nitro group was placed at C(4) in **19.2** the peptide corresponding to **19.3** did not undergo ligations, as the sulfur was no longer



**Scheme 19**

nucleophilic enough.

A more advanced version of the approach summarized in Scheme 19 is shown in Scheme 20.[46] In this case, a di- or trimethoxybenzyl unit was used. This unit bears a protected sulfur *ortho* to the benzylic carbon (see **20.1**). Bromide displacement, with stereochemical inversion (**20.1** → **20.3**), gives a resin-bound peptide carrying the specially derivatized *N*-terminal amino acid. No epimerization (<2%) of the *N*-terminal amino acid was observed with small model peptides using this preparative method. Deprotection of the sulfur and cleavage from the resin (both done with HF), ligation with peptide thioesters **20.5**, and acyl transfer (**20.3** → **20.4** → **20.6** → **20.7**) sets the stage for removal of the auxiliary and release of the native peptide. When X = H,



**Scheme 20**

the auxiliary is removed (**20.7** → **20.8**) with HF but, for the trimethoxy series (X = OMe) $CF_3CO_2H$ containing *i*-$Pr_3SiH$ is adequate. The methoxy group at C(5) increases the efficiency of the thioester exchange – which is usually, the rate-limiting step.

In order to demonstrate the effectiveness of the methodology, the 62-amino acid SH3 domain of α-spectrin was synthesized[46] by ligation at a Lys-Gly site. This site was chosen as representing a typical ligation site in a protein, it being already established[18,43,47] that the rate of ligation is sensitive to the nature of the *C*-terminal amino acid thioester: the rate is high with Gly and His thioesters and

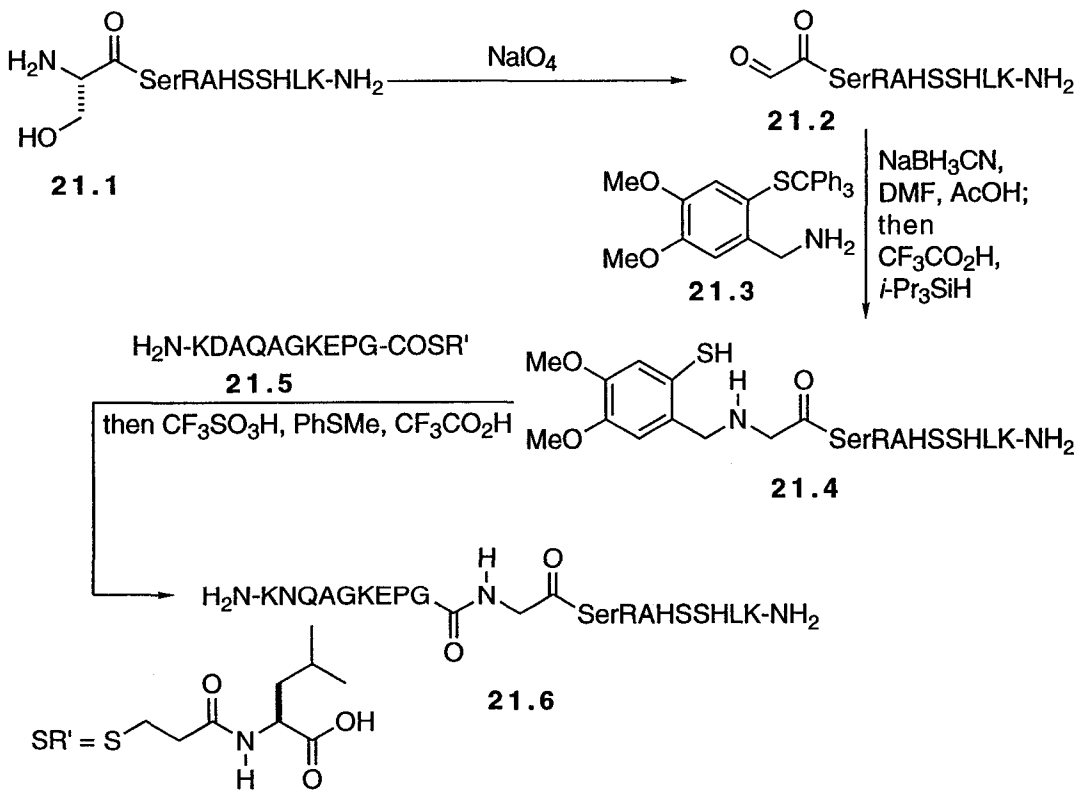
low for thioesters of β-branched amino acids. These extreme cases are not regarded[46] as being representative of the ligation properties of the majority of amino acids such as Leu and Lys.

In order to synthesize the protein, the segment α-spectrin[1-27] thioester, i.e. $H_2N$- MDETGKELVLALYDYQEKSPREVT-MKK-$SC_6H_5$ and Dmb-α-spectrin[28-62], i.e. HN(dimethoxy auxiliary)-GDILTLLNSTNKDWWKVEVNDRQGFVPAAYVKKLD-OH (cf. **20.4**), were added to an aqueous solution of 6 M guanidine hydrochloride containing a phosphate buffer initially at pH 8.5. The mixture had pH 7 after addition of the peptides, and the coupled product was isolated in 66% yield.

The scope of the procedure was investigated further by attempting ligations at three additional sites in α-spectrin-like peptides, involving ligation of a Gly-thioester and a derivatized *N*-terminal Gly, a Gly-thioester and a derivatized *N*-terminal Ala, and an Ala-thioester and a derivatized *N*-terminal Ala. For these experiments segments of similar length to those used initially in the synthesis of the SH3 domain of α-spectrin were again used. The Gly-$SC_6H_5$/(Auxiliary)Gly coupling (with the dimethoxy auxiliary) was rapid (half-life 0.2 h); the Gly-$SC_6H_5$/(Auxiliary)Ala coupling had a half-life of 5 h (dimethoxy auxiliary); no reaction was observed on attempting a Ala-$SC_6H_5$/(Auxiliary)Ala ligation. Lys-$SC_6H_5$/(Auxiliary)Gly couplings with either the di- or trimethoxy auxiliaries had $t_{1/2}$ of 2 h. The fact that Lys-$SC_6H_5$/(Auxiliary)Gly couplings are slower than Gly-

$SC_6H_5$/(Auxiliary)Gly couplings is consistent with ester exchange being the rate-limiting step, while the large rate decrease between derivatized Gly ligations and derivatized Ala ligations with Gly thioesters suggests that the rate-limiting step is acyl transfer in these two cases. The experiments with **20.1** (X = H or OMe) suggest that these auxiliaries are very useful for ligations at Gly-Gly sites.

The auxiliary of type **20.1** (X = H) can be introduced in a different way[48] from that shown in Scheme 20. Periodate oxidation of peptide segment **21.1** (Scheme 21) carrying an *N*-terminal serine affords the corresponding segment with an *N*-terminal glyoxyloyl group (**21.2**), and this can be subjected to reductive amination with amine **21.3**. Deprotection of the

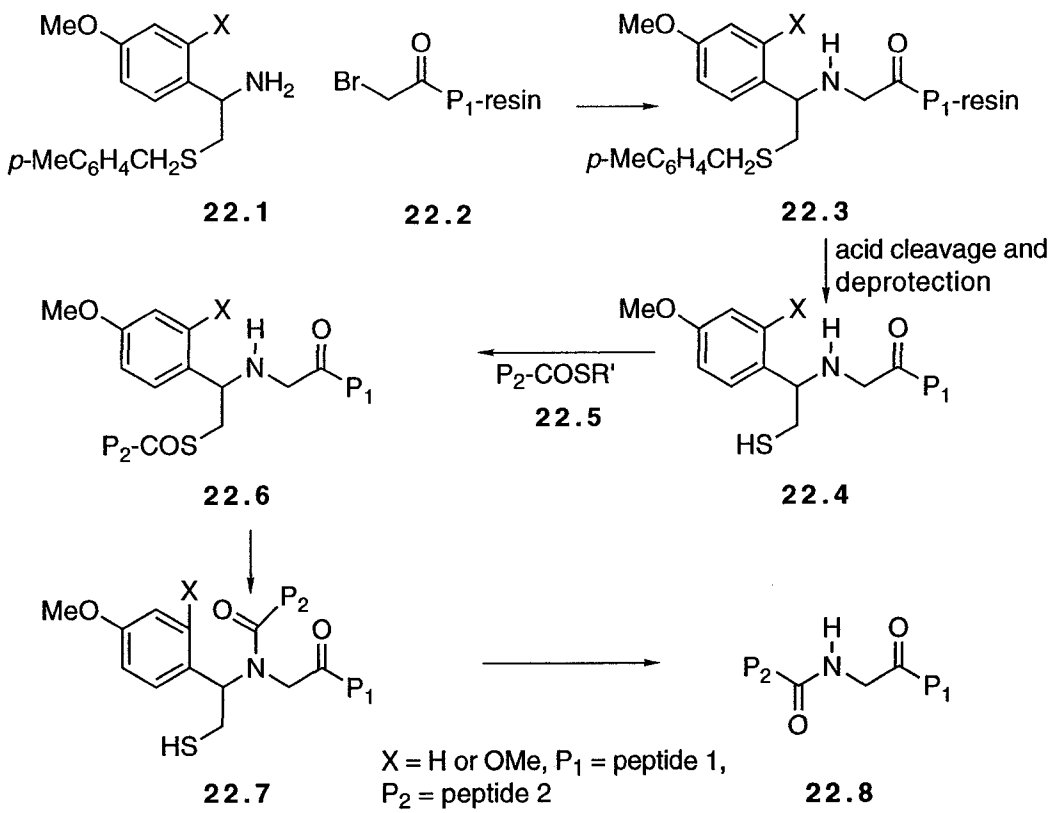


**Scheme 21**

sulfur ($CF_3CO_2H$, *i*-$Pr_2SiH$) then affords a peptide with an *N*-terminus correctly constituted for ligation with a peptide thioester (**21.5**) and acyl transfer under standard conditions (aqueous guanidine hydrochloride, pH 7.2, PhSH). Finally, removal of the substituted benzyl unit with acid gives the native peptide **21.6**, having Gly at the site of ligation (**21.4** → **21.6**).

Another approach to allow ligation at a non-cysteine residue, by means of an auxiliary, is based on the amines **22.1** (X = H or OMe) (Scheme 22).[47] The auxiliaries have the essential property of resisting cleavage under the acidic conditions used in peptide synthesis as long as they are attached to an *amine* nitrogen; however, after ligation and acyl transfer, the attachment is to an *amide* nitrogen (see **22.7**), and each auxiliary is now easily cleaved by acid.

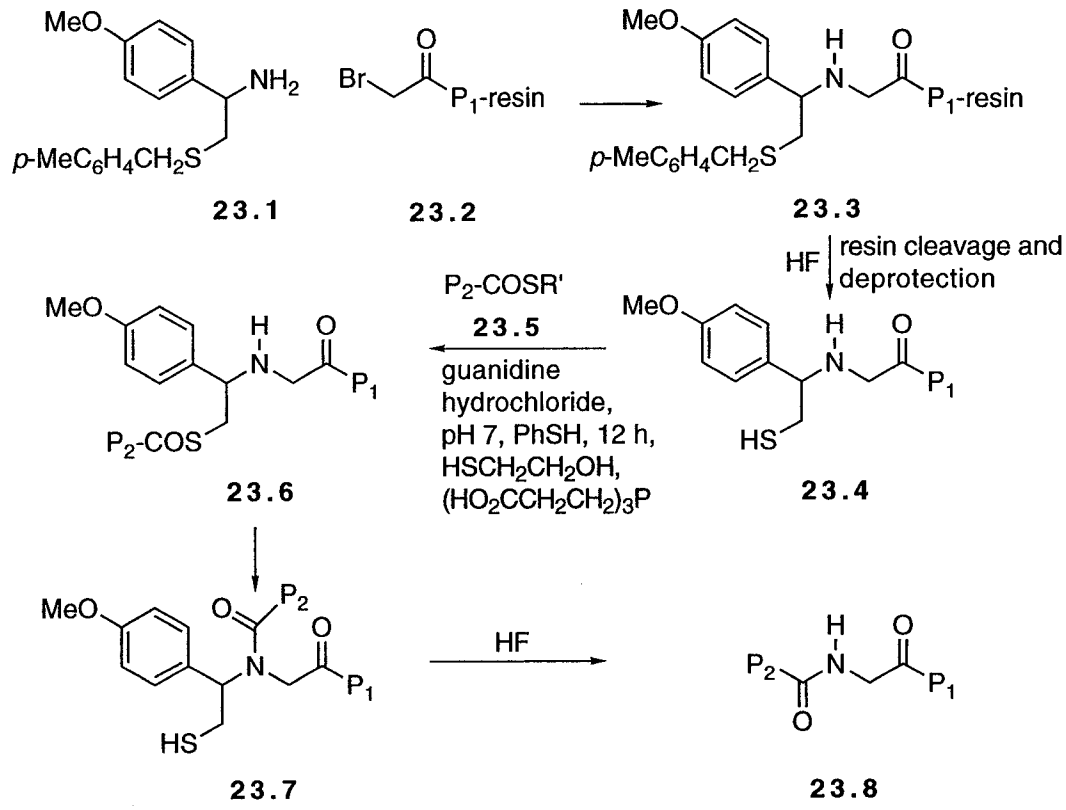
The auxiliaries are attached to a resin-bound peptide (prepared by Boc-chemistry) via bromide displacement, as shown in Scheme 22 (**22.1** + **22.2** → **22.3**).[47] After deprotection and resin cleavage (**22.3** → **22.4**), reaction with a peptide (**22.5**) whose carboxyl terminus is in the form of a thioester results in ligation and acyl transfer (**22.4** → **22.6** → **22.7**). Finally, the auxiliary is removed, giving the native peptide **22.8**. When X = H, 95% HF and 5% *p*-cresol or $CF_3CO_2H$-$Me_3SiBr$ are used to remove the auxiliary; when X = OMe the reagent system is 95% $CF_3CO_2H$, 2.5% $Et_3SiH$ and 2.5% water.



**Scheme 22**

The approach was tested by the ligations of HN(Auxiliary)-Gly-Ser-Tyr-Arg-Phe-Leu-OH with thioesters of peptides containing 3, 31, 35 and 67 residues, the *C*-terminal thioester being Gly, Ala, Lys, and His, respectively. Ligation and acyl transfer involving Gly- or His-derived thioesters required 16 h, but with Ala- and Lys-derived thioesters 40 h were needed for comparable yields. In the case of the Ala-derived thioester, results were better when X = H than when X = OMe, but the difference was small (92% yield versus 85%).

The monomethoxy auxiliary has been used in the synthesis of cytochrome b562, which contains 106 amino acid residues



$P_2$ = HN-A[1]DLEDNXETLNDNLKVIEKADNAAQVKDALTKMRAAALDAQKATPPKL-EDKSPDSPEMKDFRH[63], X = Met or SeMet

$P_1$ = HN-F[65]DILVGQIDDALKLANEGKVKEAQAAAEQLKTTRNAYHQKYR[106]-OH

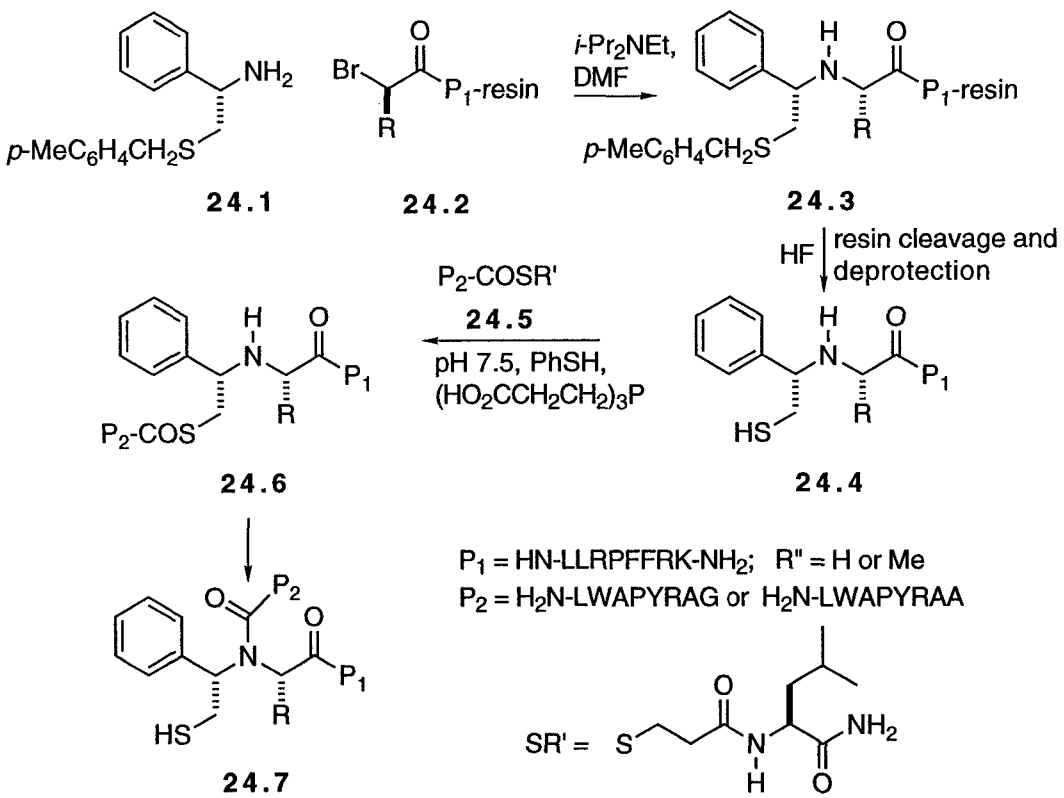
**Scheme 23**

and has no Cys (Scheme 23).[42]

The thioester segment **23.5** was made by solid phase peptide synthesis using Boc-chemistry on a thioester-generating resin, and the other segment (**23.2**) was also made on a resin. Nucleophilic displacement then served to attach the auxiliary (**23.2** → **23.3**). Following deprotection and cleavage from the resin the two segments were used for ligation and acyl transfer, and the auxiliary was removed with HF. The corresponding [SeMet[7]]cytb562 was also made.

The use of benzylamine auxiliaries introduces a new

asymmetric center on the modified *N*-terminus, and the effectiveness of both isomers has been examined.[49] The auxiliary **24.1** and its enantiomer were each incorporated as the *N*-terminus of a polypeptide on a solid support by bromide displacement with inversion to produce, in the case of enantiomer **24.1**, the *N*-protected peptide **24.3**. Deprotection and cleavage from the resin gave **24.4**, which was subjected to



**Scheme 24**

transthioesterification with **24.5** under standard conditions for acyl transfer. The residual auxiliary on the product (**24.7**) is not removable. Two auxiliary-modified *N*-terminal amino acids were studied – Gly (R = H in **24.3**) and Ala (R = Me in **24.3**), and for each one both enantiomers of the

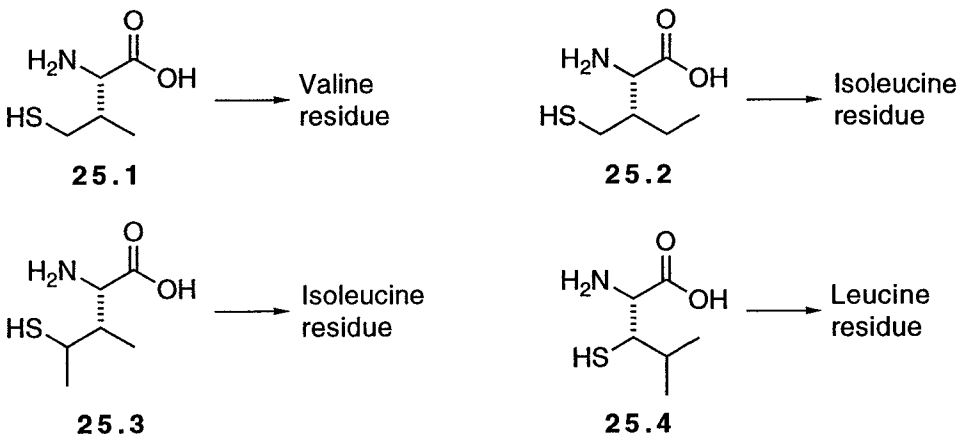
auxiliary were tested. For a derivatized Gly terminus the ligation and acyl transfer rate is independent of the stereochemistry of the auxiliary, at least for reaction with a Gly thioester or Ala thioester. However, when the auxiliary (either enantiomer) was attached to an Ala residue (R = Me in **24.4**), only the initial ligation occurred with a Gly thioester and an Ala thioester, but not the acyl transfer. The effect of pH and solvent was not investigated, however.

Other studies have shown[18] that as far as the thioester component is concerned, only the β-branched amino acids and Pro have ligation rates significantly slower than Ala. In the reactions of Scheme 24 the acyl transfer is rate-determining, and addition of PhSH, commonly added to activate thioesters for ligation, had no effect.

*(c) Conversion of Cys at the ligation site into Ala*[50]

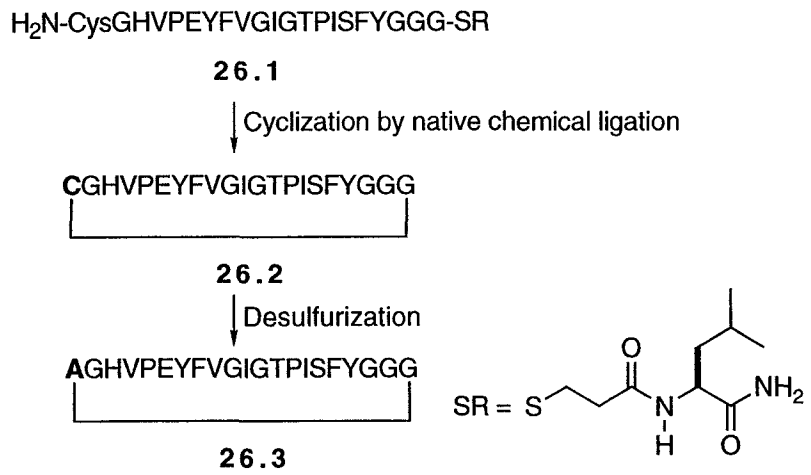
The utility of the standard native chemical ligation has been extended by the conceptually simple method of desulfurizing the Cys after ligation, so as to generate an Ala residue. It should be noted that Ala is one of the most abundant amino acid residues in proteins.[50] The desulfurization was best effected with Raney nickel. Of course, other Cys residues (even Acm-protected Cys) cannot be present in the target peptide (they would also be desulfurized), and care must be exercised to control the reaction time when Met is present, as this residue is itself

slowly desulfurized. Unnatural sulfhydryl amino acids, such as **25.1-25.4**, can be used, since these afford natural amino acids at the site of ligation on desulfurization. This possibility was demonstrated by coupling AcHN-$M^{1}$TYKLILNGKTLKGETTTEAVDA$^{23}$-SR with HomoCys-AYGGFL-$NH_2$; desulfurization of the product gave AcHN-$M^{1}$TYKLILNGKTLKGET-TTEAVDA-Abu-AYGGFL-$NH_2$ (Abu = α-aminobutyric acid residue). As indicated in Scheme 25, unnatural amino acids **25.1-25.4** would lead to Val, Leu, or Ile residues at the ligation site instead of Cys.



**Scheme 25**

The method was first demonstrated by synthesis of microcin J25 (**26.3**), a small cyclic peptide containing 21 amino acid residues. It contains one Ala but no Cys. A linear analog of microcin J25 was made that had a *C*-terminal thioester and an *N*-terminal Cys in place of the natural Ala. Native chemical ligation gave a cyclic analog and desulfurization afforded the natural material (Scheme 26).



**Scheme 26**

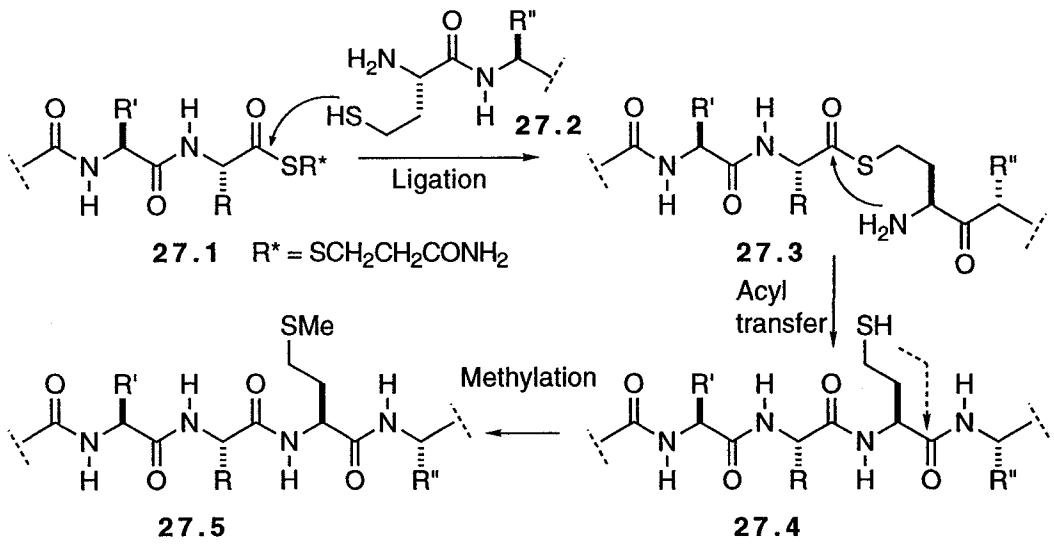
Peptide **26.1** was made by solid phase methods. When exposed to the standard conditions of native chemical ligation the cyclized peptide **26.2** was formed (50% isolated yield). Treatment with $Pd/Al_2O_3$ in 20% aqueous AcOH served to convert the Cys into an Ala, giving the natural peptide **26.3** (52%).

The above method was applied to a linear peptide called PGB1. This is a 56-amino acid immunoglobulin binding domain from *Streptococcus*. It contains six Ala residues but no Cys.[51] The *N*-terminal thioester segment used corresponds to residues 1-23 [AcHN-$M^1$TYKLILNGKTLKGETTTEAVDA$^{23}$-SR] and the *C*-terminal segment corresponds to residues 24-56, in which $Ala^{24}$ was replaced by Cys in order to permit ligation. The ligated product $N^{\alpha}$-Ac[$Cys^{24}$]PGB1 was subjected to desulfurization with $Pd/Al_2O_3$ in a buffer, affording $N^{\alpha}$-Ac-PGB1 in 80% yield. The desulfurization was selective, and the methionine of $N^{\alpha}$-Ac-PGB1 did not react. Similarly, [$Cys^{49}$]barnase,[4] an analog of

the natural peptide, was converted into [Ala$^{49}$]barnase by desulfurization with $Pd/Al_2O_3$. These experiments showed that desulfurization is compatible with all the natural amino acids.

*(d) Conversion of homocysteine at the ligation site into Met*

The above desulfurization method is related to earlier work[52] in which ligation was effected using homocysteine (Hcy) instead of Cys, and the resulting thiol at the ligation site was methylated so that a Met was ultimately present at the ligation site (Scheme 27).



**Scheme 27**

Typically, the ligation is done at pH 7.6 in the presence of an excess of $(HO_2CCH_2CH_2)_3P$, which prevents disulfide formation and which also accelerates the reaction. Transthioesterification and acyl migration were usually complete within 4 h. A number of model peptides were made

from the thioesters and *N*-terminal Hcy peptides, as shown in Scheme 28. The peptides were made by solid phase methods, using Boc-chemistry for the thioesters (thioesters are attacked by the nucleophiles used repetitively to remove Fmoc groups) and either Boc- or Fmoc-chemistry for the *N*-terminal Hcy peptides.

| **Thioesters** | ***N*-Terminal Homocysteinyl peptides** |
|---|---|
| $H_2N$-KLYG-SR | $H_2N$-Hcy-KLQDV-OH |
| $H_2N$-KLYG-SR | $H_2N$-Hcy-ARVELKKLQDV-OH |

R = $SCH_2CH_2CONH_2$

**Scheme 28**

In addition, two *N*-terminal Hcy peptide thioesters, $H_2N$-Hcy-KYGGFL-SR and $H_2N$-Hcy-SVSEIQLMHNLGGKHLNS-SR, were subjected to the ligation conditions and were found to undergo cyclization.

Several side reactions were observed, but can be minimized by proper attention to the experimental procedure. It should be noted that the initial products are susceptible to degradation caused by attack of the Hcy sulfhydryl group on the adjacent carbonyl via a five-membered transition state (see **27.4**, dotted arrow).

The products from these ligations were methylated on sulfur, using methyl *p*-nitrobenzenesulfonate, reaction being stopped before methylation of lysine ε-amino groups or of imidazole rings occurred.

*(e) Conversion of Cys at the ligation site (and elsewhere) into dehydroalanine*[53]

A number of peptides – mainly cyclic – containing from 5-14 amino acids were made by native chemical ligation (Scheme 29) and all the Cys residues were then converted into dehydroalanine residues. The conversion was effected by *S*-cyanation (-SH → -S-CN) with 1-cyano-4-dimethyl-aminopyridinium tetrafluoroborate, followed by elimination by treatment with *i*-$Pr_2NEt$. Alternatively, each thiol group was methylated and then oxidized to a sulfoxide, which underwent elimination on treatment with DBU. The fact that Cys not at the ligation site is also changed is a limitation of this method.

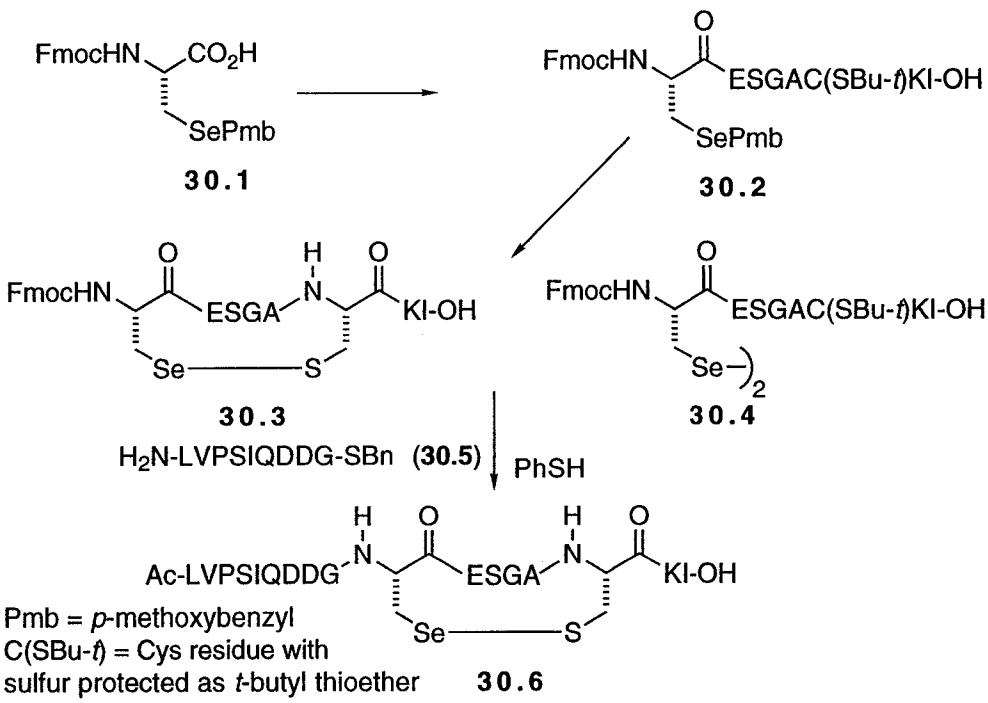
**Scheme 29**

*(f) Selenocysteine at the ligation site*

Several studies have been reported on the use of

selenocysteine instead of Cys. The protected selenocysteine **30.1** has been incorporated as the *N*-terminus of a short peptide (see **30.2**).[54] Oxidative deprotection of the selenium, using iodine, gave a mixture of **30.3** and **30.4**, and both of these underwent ligation and acyl transfer when treated with the thioester **30.5** in the presence

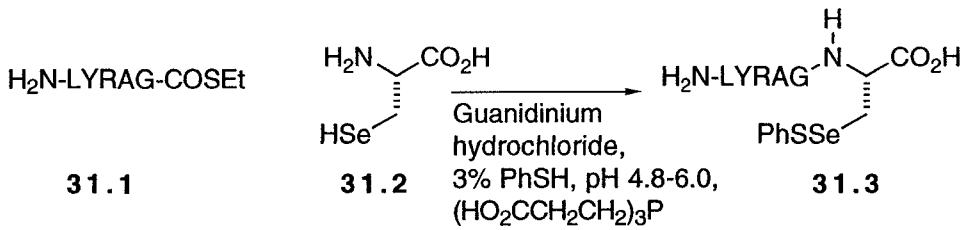


**Scheme 30**

of PhSH, which generates the free selenol from either **30.3** or **30.4**. The reactions took 24 h under the conditions used; and, given the greater acidity of a selenol compared with a thiol, the more nucleophilic nature of a selenolate, and the fact that aminolysis of selenoesters is much faster than of thioesters,[55] it is surprising that the ligations were not faster. Possibly, the rate-limiting step is formation of the

free selenol from **30.3** or **30.4**. The use of selenocysteine might offer some opportunities for further modification of the final products by deselenation (to generate an Ala residue), but this does not appear to have been examined.

A more advanced study of selenocysteine-mediated native chemical ligation has also been reported.[55]

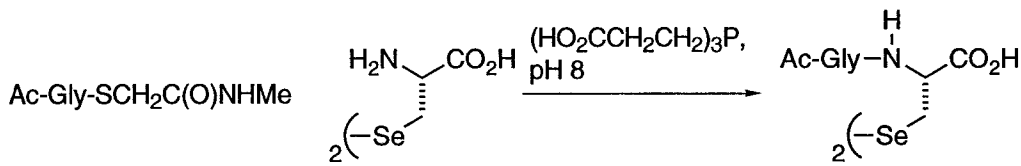


**Scheme 31**

The pentapeptide thioester **31.1** underwent smooth ligation and acyl transfer with selenocysteine (**31.2**), generated *in situ* from selenocystine by reaction with $(HO_2CCH_2CH_2)_3P$, giving **31.3** (Scheme 31).[55] The corresponding reaction with Cys went at about the same speed. Selenocysteine-mediated native chemical ligation was then used[55] to make a selenocysteinyl derivative of bovine pancreatic trypsin inhibitor, a 58-amino acid polypeptide that is an inhibitor of serine proteases whose natural form had previously been made by standard native chemical ligation.[25] Conventional[56] Fmoc solid-phase peptide synthesis on a Pam resin, followed by cleavage from the resin by treatment with $Me_3Al$ and EtSH, gave the required 37-amino acid thioester segment $H_2N$-$R^1$PDFCLEPPYTGPCKARIIRYFYNAKAG-LCQTFVYGG$^{37}$-COSEt. The other segment ($H_2N$-U$^{38}$RAKRNNFKSAEDCM-

RTCGGA$^{58}$-OH; U = selenocysteine) was synthesized on a Wang resin, using *p*-methoxybenzyl protection for the selenium during assembly of the peptide. The material was obtained as a mixed selenosulfide formed between Sec$^{58}$ (Sec = selenocysteine) and either Cys$^{51}$ or Cys$^{55}$. The ligation was effected under similar conditions to those used for the model study summarized in Scheme 31.

Another advanced study on the use of Sec$^{57}$ in place of Cys led to the synthesis of a peptide with 124 amino acid residues.



**32.1** **32.2** **32.3**

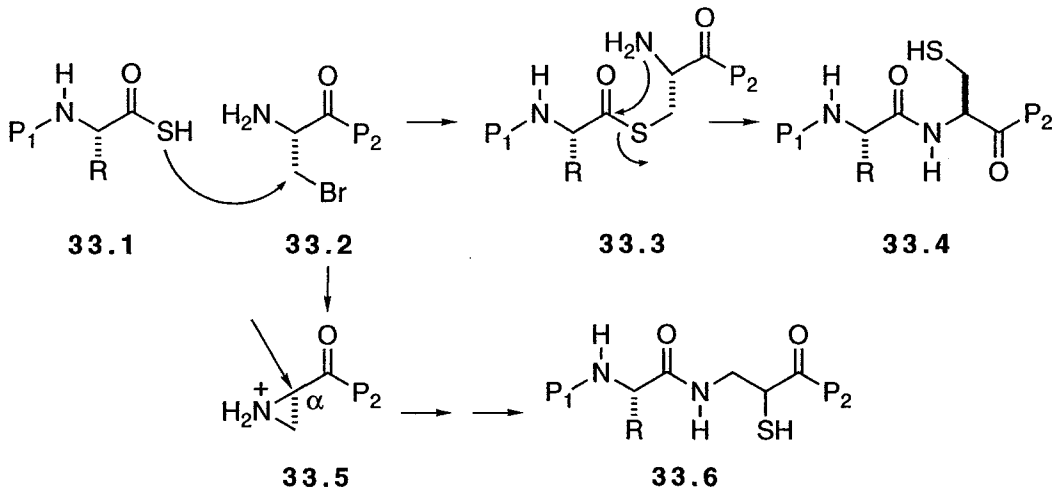
**Scheme 32**

First, the simple model ligation shown in Scheme 32 was performed, and worked without incident. In a related model, the ligation was $10^3$ faster with Sec than with Cys at pH 5, as expected from the greater nucleophilicity of $RSe^-$ compared with $RS^-$, the lower $pK_a$ of RSeH than RSH, and faster aminolysis of selenoesters than thioesters. Next, a selenium analog of ribonuclease A was made. A fragment corresponding to residues 1-109 with a *C*-terminal thioester was made by recombinant DNA technology, and standard solid phase methods were used to synthesize a peptide corresponding to residues 110-124, but with Sec at position 110. The two segments were

ligated, and the resulting protein was folded to material that had the same activity as wild-type ribonuclease A.

**Variations of the native chemical ligation that still afford a native peptide backbone**

*(a) use of an N-terminal β-bromoalanine*



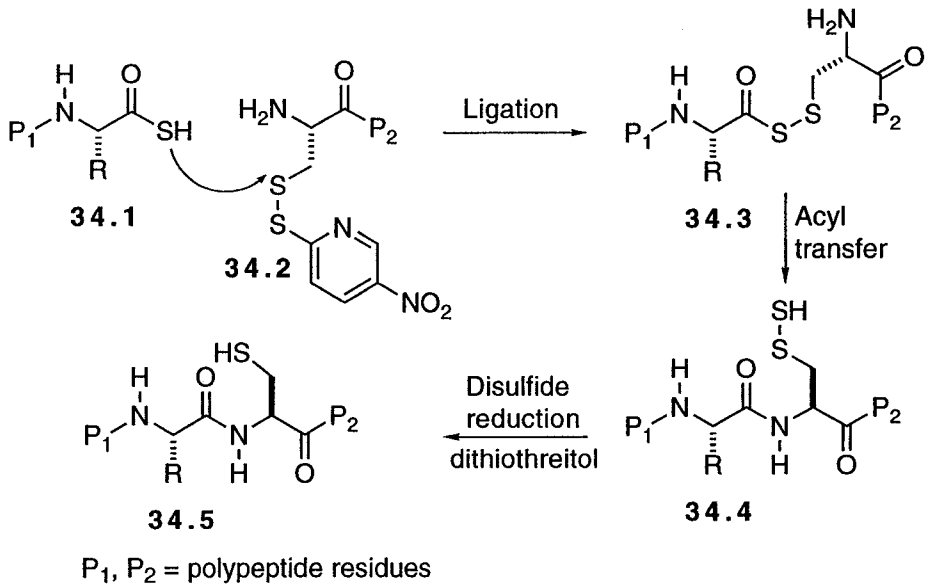
**Scheme 33**

Another method that accomplishes the same overall result as linking an *N*-terminal Cys with a *C*-terminal thioester is summarized in Scheme 33.[23] Here a thioacid (**33.1**) is used to displace bromine from an *N*-terminal β-bromoalanine (**33.2**). The resulting intermediate, which is identical to that obtained by the thioester-Cys approach, rearranges to the native peptide **33.4**. Some of the undesired ligation-rearrangement product **33.6** was also formed by initial attack on the aziridinium ion **33.5** at $C^{\alpha}$. This pathway was suppressed at low pH (3% at pH 4.7, 40% at pH 6.2) in the

case of coupling the single amino acids Leu-SH and BrAla. The β-bromoalanine method was used to couple SAKL$^{\alpha}$COSH with BrAlaPGGNAC(Acm)V-OH, the coupled product being obtained in 85% yield.

(b) *Use of acyl disulfides*

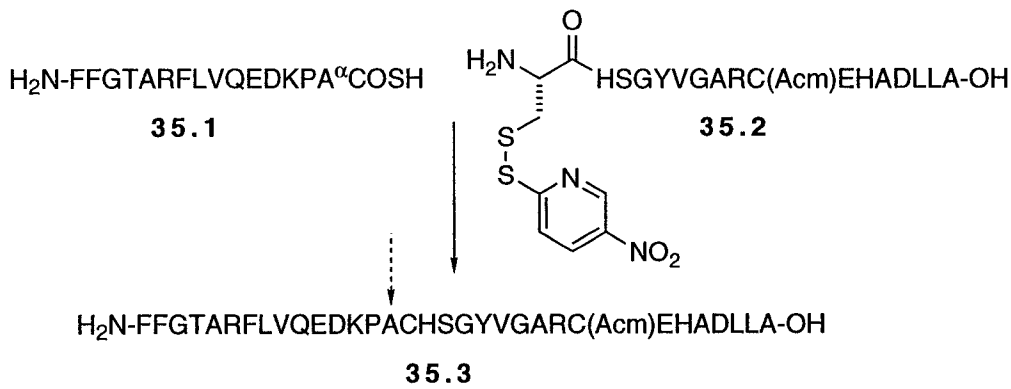
An alternative way of ligating two peptide segments is summarized in Scheme 34.[58]



**Scheme 34**

In this approach the $^{\alpha}$COSH reacts with a derivatized *N*-terminal Cys to form an acyl disulfide **34.3**. This undergoes intramolecular rearrangement via a six-membered transition state (**34.3** → **34.4**). Finally, reduction of the disulfide link in **34.4**, using dithiothreitol, releases the native peptide with a Cys at the ligation site. The method was tested by synthesis of a 32-residue model peptide (Scheme

35).

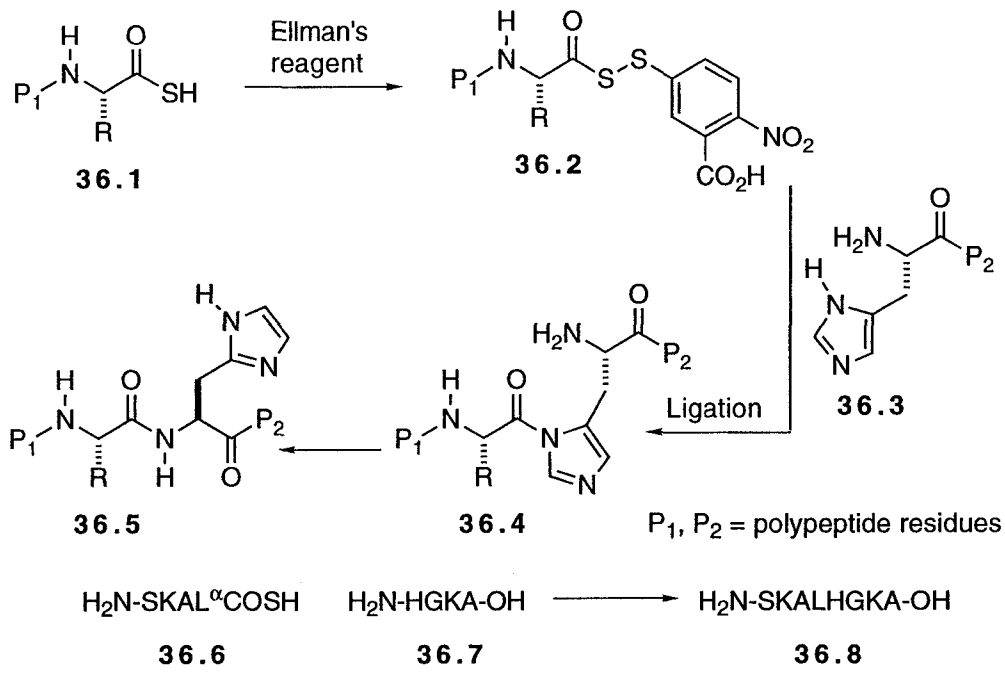


**Scheme 35**

The individual peptides were made by solid phase methods and the thiopyridyl unit was attached to the *N*-terminal Cys by reaction with 2,2'-dithiobis(5-nitropyridine). When solutions of **35.1** and **35.2** were mixed in aqueous MeCN at pH 2, the initial ligation occurred immediately. The pH was then adjusted to pH 6 and, after a further 10 min reduction with dithiothreitol gave the final product **35.3**. The whole process is reported to be efficient, but no yield was given. The site of ligation in **35.3** is marked by an arrow.

Acyl disulfides related to **34.2**, but lacking the nitro substituent have also been used [59] Two peptide thioacids $H_2N$-YSAELV-SH and $H_2N$-YSAELG-SH were coupled with $H_2N$-C($\beta$S-pyridyl)YSELA-$NH_2$ in good yield (>75%) within 20 min.[59]

A different method of using acyl disulfides was also examined,[60] but in this case the acyl terminus was activated and the other segment carried a His residue at its *N*-terminus instead of Cys (Scheme 36).



**36.1** **36.2** **36.3** **36.4** **36.5**

$H_2N$-SKAL$^{\alpha}$COSH + $H_2N$-HGKA-OH ⟶ $H_2N$-SKALHGKA-OH

**36.6** **36.7** **36.8**

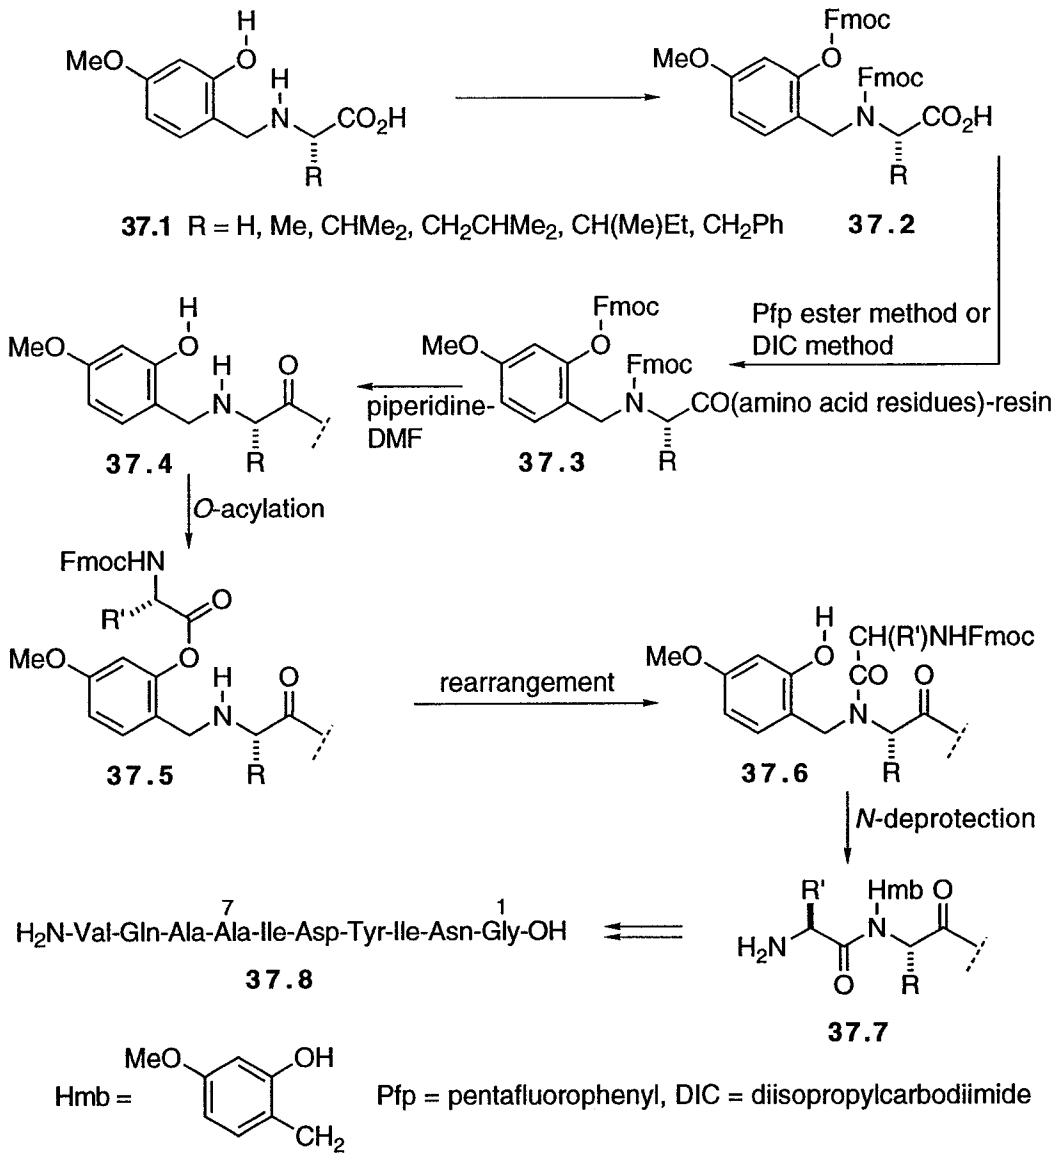
**Scheme 36**

Both segments **36.1** and **36.3** were made by standard solid phase synthesis. No significant coupling took place when the segments were mixed together, but addition of Ellman's reagent [5,5'-dithiobis(2-nitrobenzoic acid)] led to the coupled native peptide. The mechanism shown in Scheme 36 has been suggested, but there is disagreement[61] about the nature of the species formed from the thioacid (**36.1**) and Ellman's reagent. The scheme was tested with simple models: coupling of **36.6** and **36.7** was performed at pH 5.7 in 1:1 water-DMF and gave the expected product **36.8** in 75% yield. In the simple model studies, **36.2** reacted selectively with $N^{\alpha}$-amines rather than with the $N^{\varepsilon}$-group of lysine. A 25-residue peptide was made by this method, this time in 60% yield, by coupling **36.6** with $H_2N$-HLSSMERVEWLRKKLQDVHNF-OH. It should be noted

that an internal His is compatible with this methodology, as demonstrated by the last example.

*(c) Use of amide nitrogen backbone protection*

Studies aimed at facilitating the synthesis of so-called[62] "difficult sequences" by solid phase peptide synthesis have examined the effect of preventing hydrogen bonding of N-H bonds by alkylating the amide nitrogen.[63] Introduction of tertiary amide bonds in peptides is most logically achieved by using precursor amino acids in which the nitrogen carries a removable alkyl group. However, for amino acids other than glycine, this type of substitution usually causes serious steric hindrance to subsequent peptide bond formation.[63] Sheppard and co-workers[63,64,65] have developed an *N*-modifying group (Scheme 37) in which the effects of steric hindrance are offset by a mechanism of acyl capture and *O* → *N* acyl transfer (**37.4** → **37.5** → **37.6**). Thus, the *N*-alkyl-substituted amino acid **37.2**[63,66] was coupled with the *N*-terminus of a resin-bound peptide so as to form **37.3**. The coupling was done with diisopropyl-carbodiimide or by use of the pentafluorophenyl ester of **37.2**. Removal of the Fmoc protecting groups and *O*-acylation gave the intermediate **37.5**, which underwent *O* → *N* acyl transfer to **37.6**. Removal of the Fmoc group and acylation of the *N*-terminus in the usual way, followed by removal of the 2-hydroxy-4-methoxybenzyl group (with $CF_3CO_2H$[66]) and resin cleavage then releases the peptide. The value of the

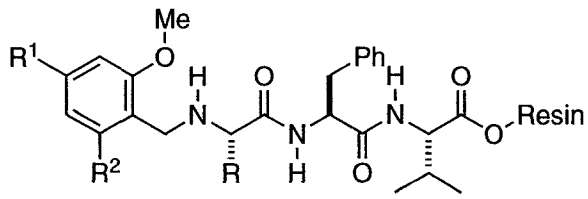


**Scheme 37**

approach summarized in Scheme 37 was shown by synthesis of the well-known "difficult sequence" acyl carrier protein 65-74 decapeptide **37.8**. This sequence undergoes strong inter-chain association after addition of the penultimate Gln residue; addition of the final Val is strongly hindered and is invariably 10-15% incomplete under standard conditions (pentafluorophenyl ester-HOBT couplings, 45 min in DMF).

Insertion of the *N*-substituted Ala derivative **37.1** (R = Me) at residue 7, enabled the final Val (residue 10) to be coupled completely under the standard conditions. The long-range effect of *N*-substitution confers flexibility in the choice of residue to be replaced. However, since *O*-acylation is intrinsically slower than *N*-acylation, the sequence of *O*-acylation followed by *O* → *N* migration will inevitably be slower than direct *unhindered N*-acylation, and it would be unwise to choose unnecessarily an intrinsically hindered site containing β-branched residues. The possible steric constraints were examined by studying the acylation of **37.4** (R = H, Me, $CHMe_2$, $CH_2CHMe_2$, CH(Me)Et, $CH_2Ph$) with a range of Fmoc-amino acid anhydrides. When R = H in **37.4**, acylation was fast (complete within 1 h) with a variety of residues including Val, Ile, and *O-tert*-butylthreonine, and so any of the common amino acids (as symmetrical anhydrides) can be used.[63,64] In the case of **37.4** [R = CH(Me)Et] 20 h were required for complete acylation with unhindered residues (Gly, Ala, *tert*-butyl glutamate), and acylation with Leu, $N^{\varepsilon}$-Boc-lysine, and *O-tert*-butyl serine was still incomplete after 20 h. *O-tert*-butyl threonine (as its symmetrical anhydride) failed to react appreciably; compound **37.4** (R = $CHMe_2$) behaved similarly. These observations indicate that Val, Ile, and probably *O-tert*-butylthreonine should not be chosen for *N*-substitution with the auxiliary unless the next residue to be coupled is unhindered. Residues with substituents of intermediate size (**37.4**, $CH_2CHMe_2$) may

require extended reaction times for addition of amino acids other than Gly, and so should not be chosen if the following residue has a β-branched structure. Pentafluorophenyl esters can also be used for coupling to the derivatized *N*-terminus.[64]



**38.1**

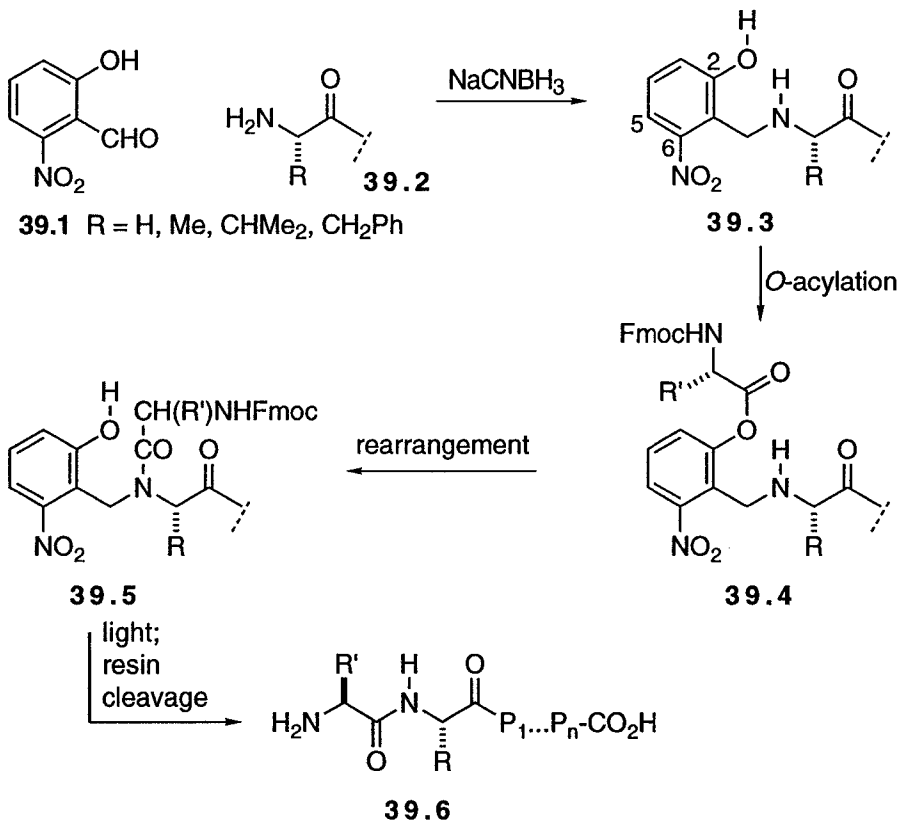
**Scheme 38**

In the above work, several observations were made about the effect of substituents $R^1$ and $R^2$ in compounds of type **38.1** (see Scheme 38). The trimethoxy species **38.1** ($R^1$ = $R^2$ = OMe) was more rapidly acylated than the less hindered **38.1** ($R^1$ = OMe, $R^2$ = H). Possibly, *ortho* methoxy substitution produces steric factors that result in a conformation that is more favorable for acylation or ensures that there is intramolecular hydrogen bonding with the adjacent N-H. However, how these possibilities enhance the rate of acylation is not clear.

The methoxy-substituted auxiliary (see **37.1**) is too acid-labile[67] for use in Boc- and benzyl-based methods but, in the *absence* of the methoxy group, the backbone protection is suitable for Boc- and benzyl protocols because the acid stability of the protecting group is now greater.[67] The desmethoxy protecting group can be removed with $CF_3SO_2H$, but

the coupling rate is lower.[67]

With the 2-hydroxy-4-methoxybenzyl auxiliary (see **37.1**), the *O* → *N* acyl transfer can be slow when hindered residues are involved[68, 69] and, as implied above there is a need for a new auxiliary with superior acyl transfer efficiency if the full potential of amide-backbone substitution is to be realized. An improved version has been developed by judicious placement of a nitro group on the benzene ring (Scheme 39).



**Scheme 39**

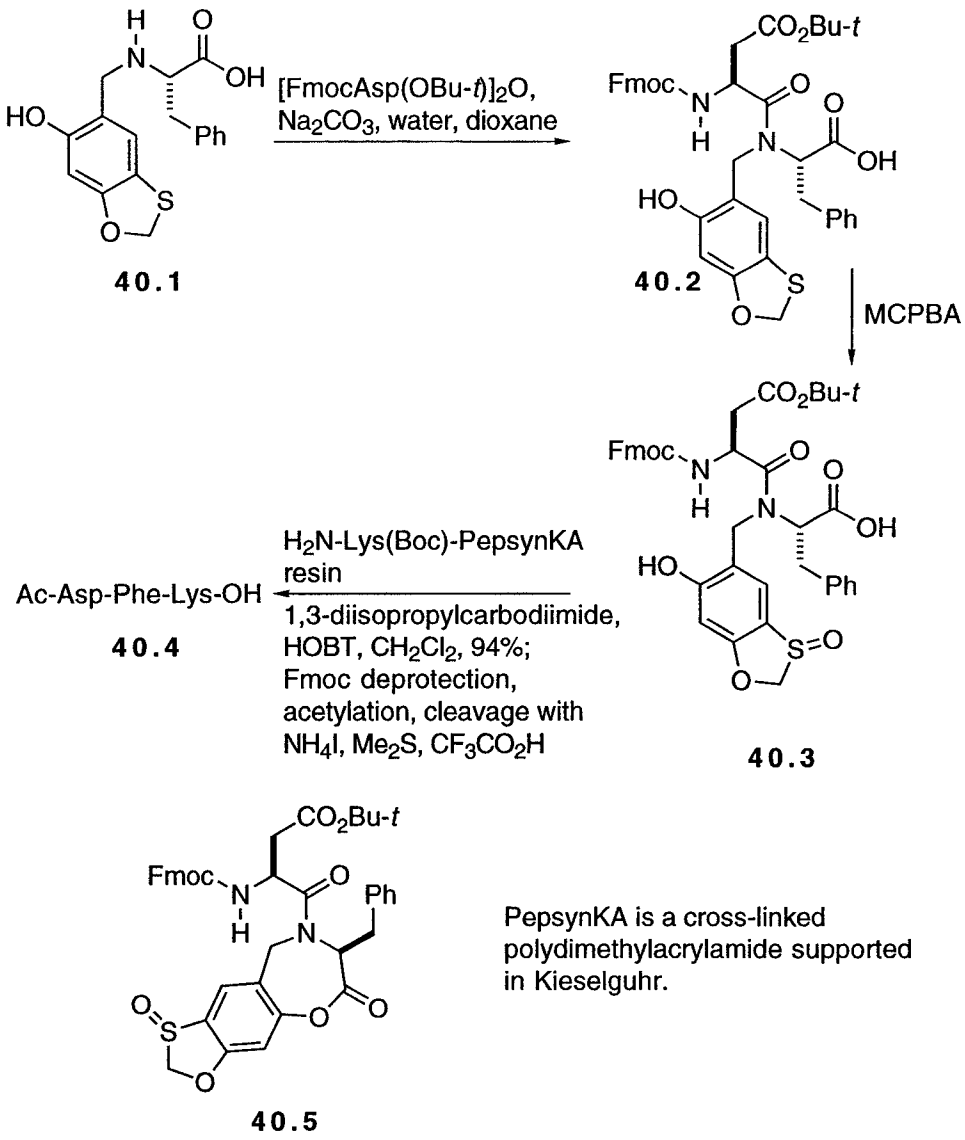
The function of the auxiliary is threefold: *O*-acylation is first required, and then *O* → *N* acyl transfer must occur,

and both steps must be efficient, irrespective of the nature of the amino acids involved. Finally, the auxiliary must be removable. The 6-nitro-2-hydroxybenzyl group (Hnb; see **39.3**) was found to be the best of several that were examined; the corresponding 5-nitro analog satisfied the first two requirements, but not the last. The 6-nitro-2-hydroxybenzyl group is attached to the *N*-terminus of a resin-bound peptide by reductive alkylation (**39.1** → **39.3**). *O*-acylation with amino acids, using the HBTU-mediated method,[70] proceeds rapidly (less than 1 min for HBTU-activated Ala and Phe, and 10 min for more than 95% acylation with the Val HBTU derivative). Subsequent *O* → *N* acyl transfer is also rapid. The Hnb group is removed by photolysis at 366 nm in MeOH in the presence of amine scavengers, such as Lys.

The effectiveness of the Hnb auxiliary in facilitating the assembly of "difficult" sequences was demonstrated by comparing the stepwise assembly of TGYIKTELISV, using standard Fmoc and *tert*-butyl solid phase methods – a process that gave an unacceptable average acylation yield of 83% – with assembly involving incorporation of the Hnb group on the third residue (Ile) from the resin linker. The average acylation yield for the preparation of TGYIKTELI(Hnb)SV was then 99.6%. Photochemical removal of the auxiliary was accomplished in 76% yield. Use of the 2-hydroxy-4-methoxy-benzyl (Hmb) auxiliary was much less successful, as coupling of Leu to the Hmb-derivitized Ile terminus (during synthesis of TGYIKTELISV) was only 21% complete in 24 h, while the

corresponding coupling using the Hnb auxiliary was quantitative. The Hnb auxiliary has also been used to facilitate cyclization of linear peptides.[71]

As described above, the method developed by Sheppard and co-workers, applies to the sequential addition of single amino acids, but backbone protection has also been used for assembly of protected peptide segments.[5] However, when the 2-hydroxy-4-methoxybenzyl group is used to protect the *C*-terminal amide bond of a fully protected segment, the rate of coupling of that *C*-terminus to the *N*-terminus of the other segment is low. This is due to formation of a 4,5-dihydro-8-methoxy-1,4-benzoxazepin-2(3*H*)-one species (cf. **40.5**) between the activated carboxyl group and the phenolic hydroxyl of the *N*-substituent; the benzoxazepinone is not a powerful acylating agent. In order to overcome this problem, an electron-withdrawing group has been placed *para* to the phenolic hydroxyl. The approach was tested in the following way. The *N*-alkylated amino acid **40.1** was coupled in the usual way with the anhydride made from FmocAsp(OBu-*t*)OH, and the product (**40.2**) was oxidized on sulfur (**40.2** → **40.3**). Coupling of this dipeptide (94%) with a resin-supported (PepsynKA is a cross-linked polyacrylamide supported on Kieselguhr[63]) Lys, followed by deprotection and cleavage, gave **40.4**. The deprotection sequence involved reduction of the (electron-withdrawing) sulfoxide to a sulfide, in order to confer acid lability. Very little (<0.25%) epimerization was observed (at the Phe site) in the coupling of the peptide



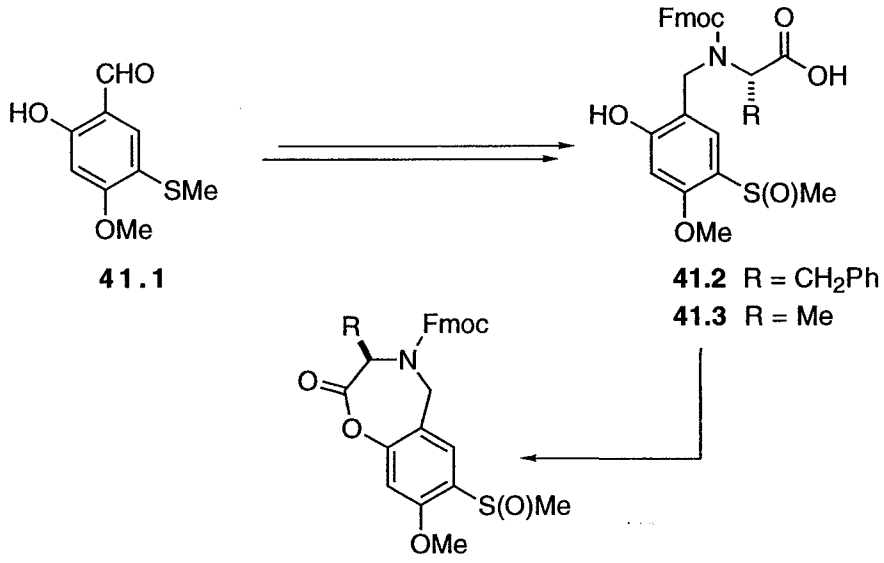
PepsynKA is a cross-linked polydimethylacrylamide supported in Kieselguhr.

**Scheme 40**

segment **40.3** with the Lys.[5] The experiment serves as a model for coupling of peptide segments without the traditional danger of epimerization at the *C*-terminus.

More recently, a related auxiliary (Scheme 41) was reported in which the sulfoxide is not part of a ring.[72] In this modification the derivatized amino acids **41.2** and **41.3** are easily prepared (by a process involving reductive

amination of aldehyde **41.1**), and they couple quantitatively through standard uronium activation, via an intermediate benzoxapin-2(3*H*)-one (**41.4**). Intermediate **41.4** is a better acylating agent than the corresponding species with H instead of S(O)Me.



**41.1**

**41.2** R = $CH_2Ph$

**41.3** R = Me

**41.4**

**41.5** $H_2N$-Tyr-Phe-Phe*-Gly-Leu-OH

**41.6** $H_2N$-Val-Gln-Ala-Ala*$^{68}$-Ile$^{69}$-Asp-Tyr-Ile-Asn-Gly-OH

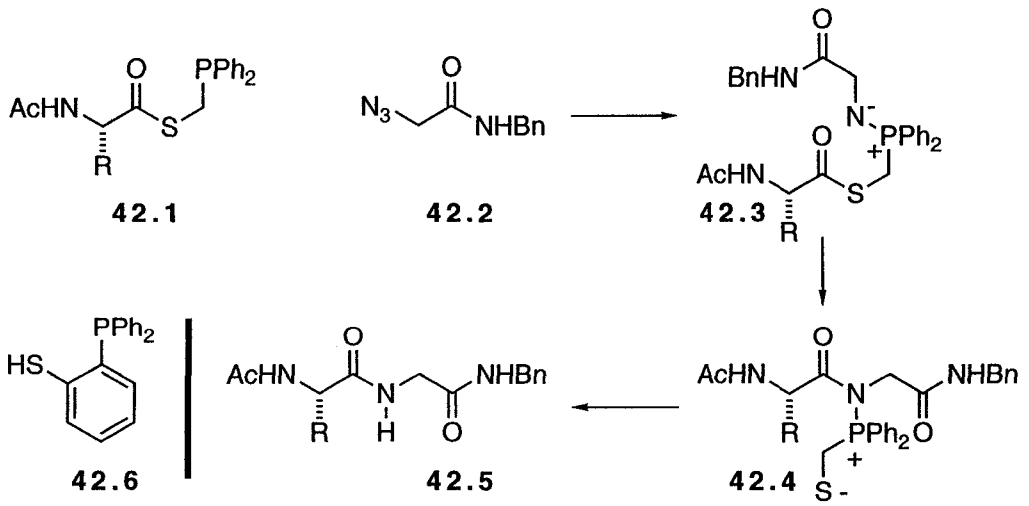
**Scheme 41**

The system was tested by use of **41.2** in the solid phase stepwise synthesis of **41.5**, and **41.3** was used in the synthesis of **41.6** (the derivatized amino acids are indicated by asterisks). In the former case, coupling of Phe onto the derivatized terminus was achieved using pentafluorophenyl ester chemistry and a reaction time of 45 min. Comparable coupling of Phe to **37.4** (see Scheme 37, R = Bn) required 24 h

with symmetrical anhydrides. The synthesis of **41.6** illustrated the application to a well-known difficult sequence (residues 65-74) from acyl carrier protein. Here, **41.3** was added after $Ile^{69}$ via BOP/HOBt/NMM activation (45 min). Removal of the Fmoc group was followed by *N*-acylation using Fmoc-Ala-$OC_6F_5$/HOBt in a standard 45-min coupling. Continuation of the sequence gave the desired decapepetide, with no detectable level of the des-Val nonapeptide.

*(d) Use of Staudinger ligation*

The thioesters **42.1** (R = H, Ph) reacted in aqueous THF at room temperature with azide **42.2** by the normal mechanism of the Staudinger reaction to give, presumably, the ylide **42.3**.[73] This underwent spontaneous rearrangement through a five-membered transition state to **42.4**, and hydrolysis then released the peptide **42.5** (80% for R =H, 92% for R = Ph). The efficiency of the reaction, using thioesters derived from



**Scheme 42**

$HSCH_2PPh_2$ was much higher than with those derived from **42.6**; in the later case the acyl transfer is by way of a six-membered ring. Thioesters **42.1** also have an intrinsic advantage over those derived from **42.6**[74]; aliphatic thioesters are more resistant to hydrolysis in aqueous solution, and such hydrolysis is likely to be a competing side reaction. The Staudinger ligation has also been examined with azides derived from Phe, Asp, and Ser without detectable epimerization.[75] These amino acids have a moderate (Phe) to high (Asp, Ser) propensity for epimerization in standard peptide couplings.[75]

The above type of ligation has yet to be tested in synthesis of large peptides.

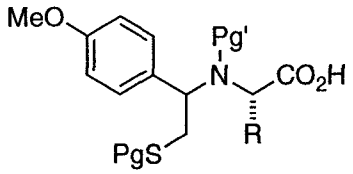
## DISCUSSION OF RESEARCH RESULTS

### Studies on the design of a general auxiliary

Our aim was to prepare compounds of type **1.1** for each of the common amino acids, as such derivatives might be useful



**1.1**

**Scheme 1**

in a general ligation and acyl transfer approach to the synthesis of proteins. If an amino acid residue derived from **1.1** could be installed as the *N*-terminus of a peptide segment then removal of the nitrogen and sulfur protecting groups and reaction with another peptide segment having a *C*-terminal thioester should result in thioester exchange, followed by *S* → *N* acyl transfer. Removal of the auxiliary would then give the native peptide. We hoped that ligation would be possible by this scheme for any value of R in **1.1**.

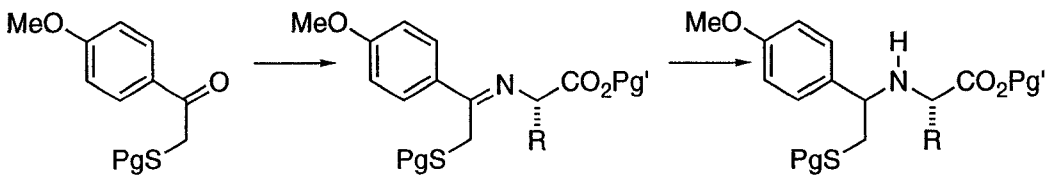
A number of approaches to **1.1** were examined and, eventually, a synthetic route was developed and applied to three amino acids. Many exploratory experiments were carried out before a successful route was found; these preliminary experiments are not described in the Experimental Section, and often full characterization data were not obtained. However, the route that was ultimately successful is reported

in detail in the Experimental Section.

**Approaches to compounds of type 1.1**

**Imine approach**

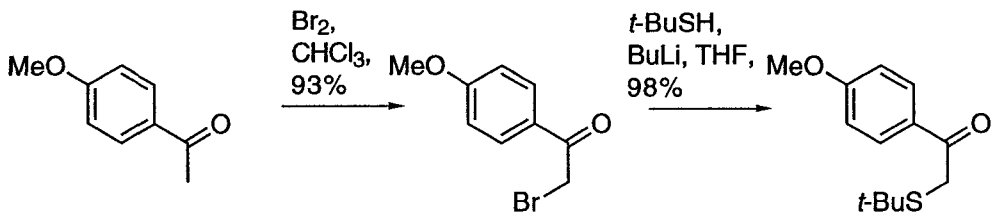
We started with the idea of reducing an imine along the lines shown in Scheme 2. An appropriate ketone (**3.3**) was made by the straightforward method summarized in Scheme 3, and proceeded without incident.



**2.1** **2.2** **1.1**

**Scheme 2**

Bromo ketone **3.2** is a known compound,[1] and was prepared by addition of $Br_2$ to a solution of ketone **3.1**; displacement with *t*-BuSLi gave the desired thio ketone **3.3**.

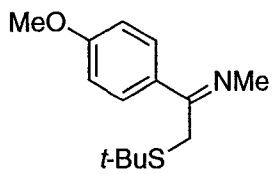


**3.1** **3.2** **3.3**

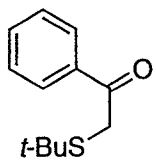
**Scheme 3**

Ketone **3.3** did not form an imine with $H_2NCH_2CO_2Me$ in the presence of either 4Å molecular sieves or of $HC(OMe)_3$, nor did it form an imine with $BnNH_2$ (also in presence of 4Å

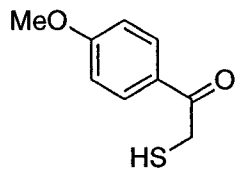
molecular sieves). A number of other attempts were made to generate imines. For example, we tried to prepare the simple imine **4.1**, using $TiCl_4$.[2] Our hope was that imine **4.1** would be more reactive than ketone **3.3** towards amines, and that any equilibrium would be driven to completion by expulsion of $MeNH_2$. Unfortunately, we were unable to prepare **4.1**.



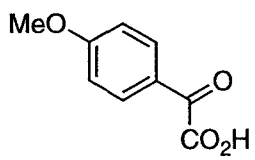
**4.1**



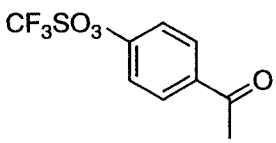
**4.2**



**4.3**



**4.4**

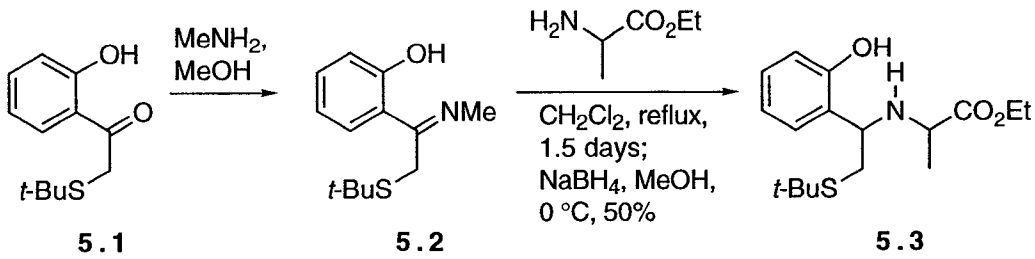


**4.5**

**Scheme 4**

The possible effect of the methoxy group was then examined by attempting to form an imine between **4.2** and $H_2NCH_2CO_2Et$ (in the presence of 4Å molecular sieves); no reaction was observed. The related ketones **4.3**, **4.4**, and **4.5** were examined next. Ketone **4.3** did not react with $MeNH_2$ in MeOH, **4.4** did not react with $H_2NCH_2CO_2Et$ (4Å molecular sieves, $ClCH_2CH_2Cl$, MeOH, heat). Likewise, **4.5** failed to react with $H_2NCH_2CO_2Et$ ($MgSO_4$, $CH_2Cl_2$).

Finally, the *ortho*-hydroxy ketone **5.1** was examined, based on the fact that salicylaldehyde forms imines readily. Indeed, phenolic ketone **5.1** did form an imine with $MeNH_2$ (in



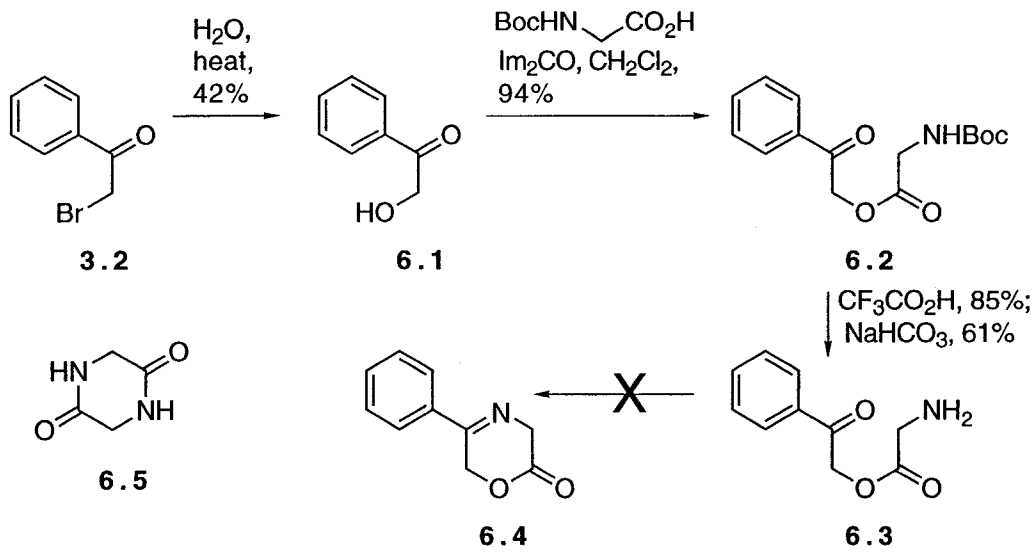
**5.1** **5.2** **5.3**

**Scheme 5**

MeOH)[3] although, under the same conditions, (±)-$H_2NCHMeCO_2Et$ did not seem to react. Condensation with (±)-$H_2NCHMeCO_2Et$ was also tried in the presence of either 4Å molecular sieves ($CH_2Cl_2$ or $ClCH_2CH_2Cl$) or of a mixture of $MgSO_4$ and $Yb(OSO_2CF_3)_3$.[4] Imine **5.2** did react, although slowly (1.5 days in refluxing $CH_2Cl_2$), with (±)-$H_2NCHMeCO_2Et$ to give a new imine which was not isolated, but was reduced *in situ* ($NaBH_4$, MeOH). The phenolic amines **5.3** were isolated in 55% yield as a mixture of isomers. Our attempt to methylate the phenolic hydroxyl selectively (MeI, $K_2CO_3$, DMF) was not successful. We were, however, able to prepare the *O*-triflate, but could not remove the oxygen under standard conditions [$Pd(OAc)_2$, $Ph_3P$, $Et_3N$, $HCO_2H$, DMF).[5]

$B_{10}H_{14}$ is reported to catalyze both imine formation and subsequent reduction.[6] Unfortunately for us, it appears to be against US Federal Law to export even small research quantities and we were not able to obtain a sample, although, admittedly, we did not make extensive enquiries.

We turned next to explore the possibility of forming an imine by an intramolecular condensation.



**Scheme 6**

Bromo ketone **3.2** was converted into the known hydroxy ketone **6.1**,[7] and this was coupled with $BocHNCH_2CO_2H$ to afford **6.2** in high yield (94%). Deprotection of the nitrogen and liberation of the resulting amine from the acid salt gave **6.3**. When this was heated in MeOH, **6.4** was not formed and, instead, the diketopiperazine **6.5** was isolated.

**Aza-Wittig approach**

We sought next to generate an aza-Wittig reagent by using the Staudinger reaction, in the hope that aza-Wittig reaction would afford an imine with ketone **3.3**. For this purpose, azide **7.2** was made from the corresponding amine by treatment with $CF_3SO_2N_3$.[8] Although the yield was very low (7%) in the single experiment carried out, we obtained enough material to generate the aza-Wittig reagent, by exposure of the azide to $Ph_3P$. This was done in the presence of ketone

**3.3**. However, no imine was formed. In a control experiment, $Ph_3P$ was added to a mixture of acetophenone and $PhCH_2CH_2N_3$.

**7.1** **7.2**

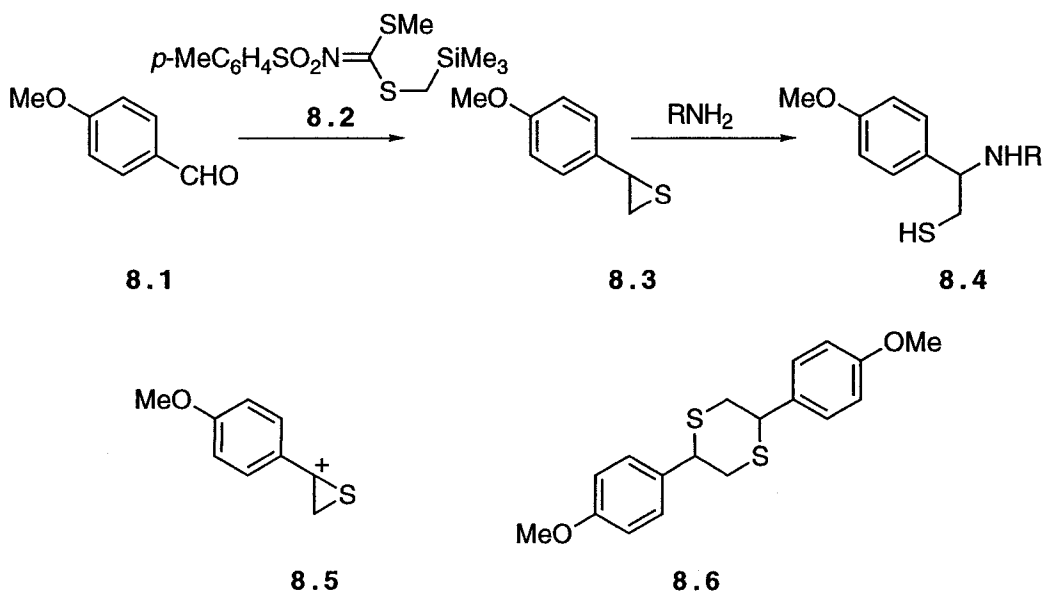
**Scheme 7**

The expected imine was not formed, and an unidentified product was isolated.

We also attempted to generate aza-Wittig reagents directly from $H_2NCH_2CO_2Et$ by treatment with $Ph_3PBr_2$ or with $Ph_2MePCl_2$,[9] but in neither case was the expected imine detected, and this approach was abandoned.

**Approaches based on opening of episulfides**

We considered that an episulfide such as **8.3** might react at the (activated) benzylic position with an amine (**8.3** →



**8.1** **8.3** **8.4**

**8.5** **8.6**

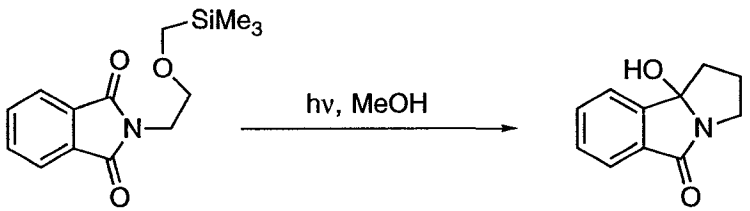
**Scheme 8**

**8.4**). Episulfide **8.3** is a known compound,[10] and was made from *p*-methoxybenzaldehyde (**8.1**) by treatment with **8.2**, as described in the literature. Treatment of **8.3** with $BnNH_2$, with or without the addition of $Hg(OCOCF_3)_2$ or $Et_3B$, caused destruction of the episulfide. When DDQ was used as the additive, in the hope of generating the species **8.5**, which would be captured by a primary amine, only the dimer **8.6** was isolated.

An attempt to alkylate episulfide **8.3** with BnBr gave no bromo sulfide, and treatment of **8.3** with $H_2NCH_2CO_2Me$ (DMF, room temperature) led to recovery of the episulfide.

**Approaches based on photocyclization of an imine**

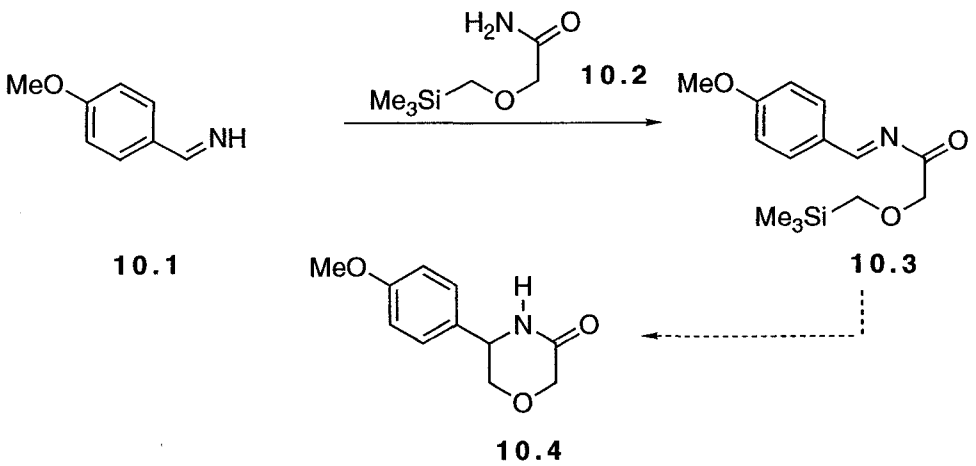
The report[11] that silane **9.1** undergoes photocyclization to **9.2** prompted us to attempt the cyclization of **10.3** to **10.4**.



**9.1** **9.2**

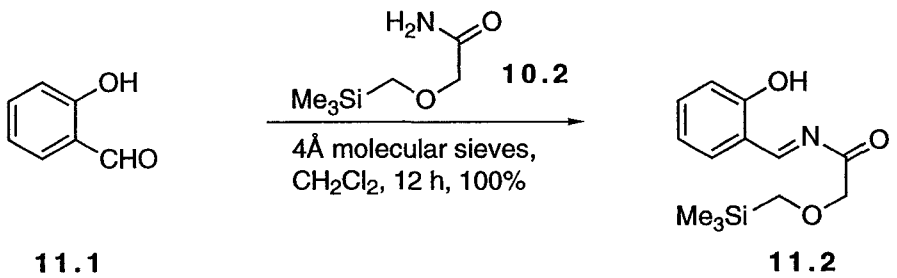
**Scheme 9**

Treatment of *p*-methoxybenzaldehyde with $NH_3$ in PhH, according to the literature procedure,[12] gave imine **10.1**. Condensation with **10.2**[13] in $CH_2Cl_2$ in the presence of 4Å molecular sieves then produced **10.3**, but this compound was unstable and was not examined further. The corresponding



**Scheme 10**

salicylaldehyde derivative **11.2**, was easily made (Scheme 11), but was inert to irradiation at 254 nm (medium pressure mercury lamp). Treatment of **11.2** with CsF in MeCN or with $Bu_4NF$ in THF – in an attempt to effect ionic ring closure – gave none of the desired product, and only complex mixtures were obtained.

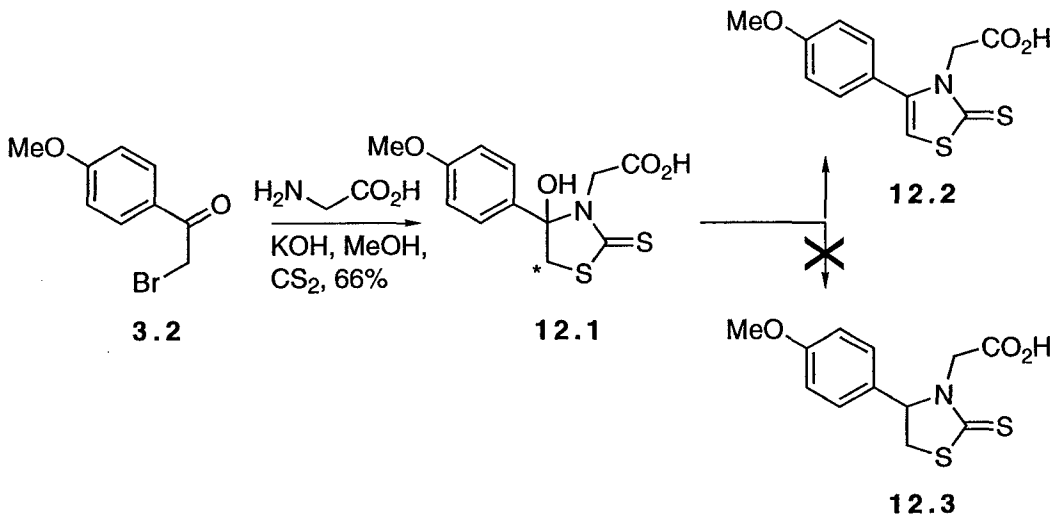


**Scheme 11**

**Dithiocarbamate approach**

Following a general procedure reported for other bromo ketones,[15] **3.2** was converted into **12.1** by successive treatment with glycine, KOH and $CS_2$, but attempt to

reductively remove the hydroxyl (**12.1** → **12.3**) ($NaBH_4$, MeOH or $BF_3.OEt_2$, $Et_3SiH$) gave instead the unsaturated compound **12.2** which, itself, was not reduced by diimide or by heating with $HCO_2H$-$Et_3SiH$. A way to avoid

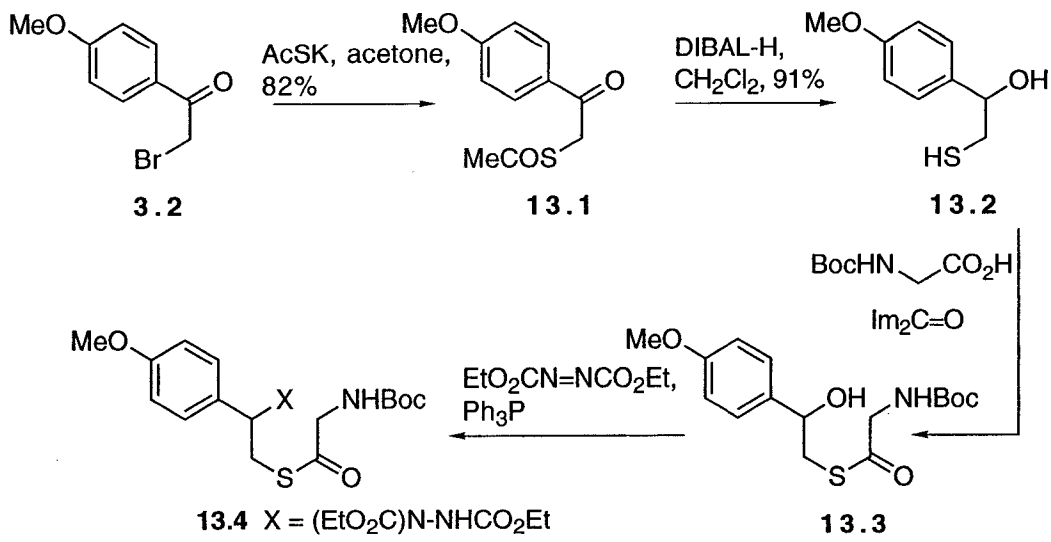


**Scheme 12**

formation of the double bond would be to prepare an analog of **12.1** in which the starred atom carries two methyl groups, but our later experiments (see page 223) showed that the heterocyclic system cannot be opened under sufficiently mild conditions that a stereogenic center on the amino acid would not be epimerized.

**Intramolecular Mitsunobu approach**

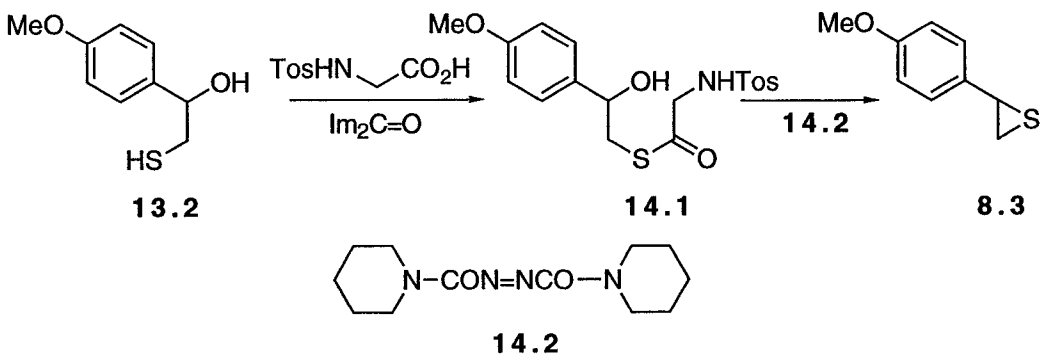
The hydroxy thiol **13.2**, readily made from the known ketone **13.1**,[16] as shown in Scheme 13, was acylated with $BocHNCH_2CO_2H$ to afford **13.3**. Under the conditions of the Mitsunobu reaction, the nitrogen failed to close onto the



**Scheme 13**

benzylic carbon and, instead, the adduct **13.4** was obtained.

When we tried the corresponding experiment with the *N*-tosyl thioester **14.1**, using a modified version of the Mitsunobu process,[17] episulfide **8.3** was obtained and again there was no cyclization through nitrogen.

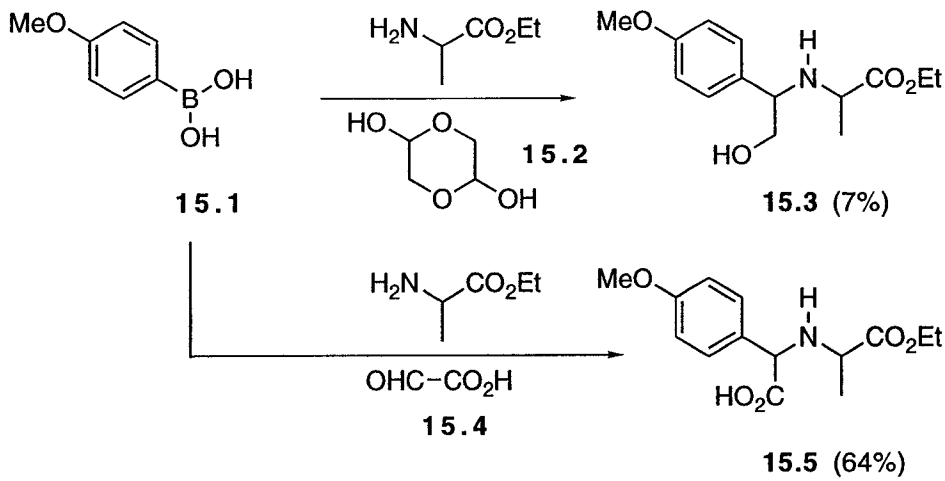


**Scheme 14**

**Boronic acid approach**

Boronic acids have been reported[18] to react with α-hydroxy- or α-carboxy aldehydes in the presence of amines to

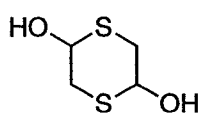
generate β-amino alcohols, and we attempted to apply this methodology to our own problem. To this end, boronic acid **15.1**



**Scheme 15**

was treated with glycol aldehyde dimer (**15.2**) and (±)-$H_2NCHMeCO_2Et$. The expected product **15.3** was indeed obtained, but only in 7% yield. When glyoxylic acid (**15.4**) was used instead, **15.5** was obtained in 64% yield. However, an attempt to reduce the carbonyl selectively, using $BH_3.SMe_2$, AcOH, $I_2$, MeOH,[19] did not give the required alcohol.

An attempt to make the known compound **16.1**[20] was



**16.1**

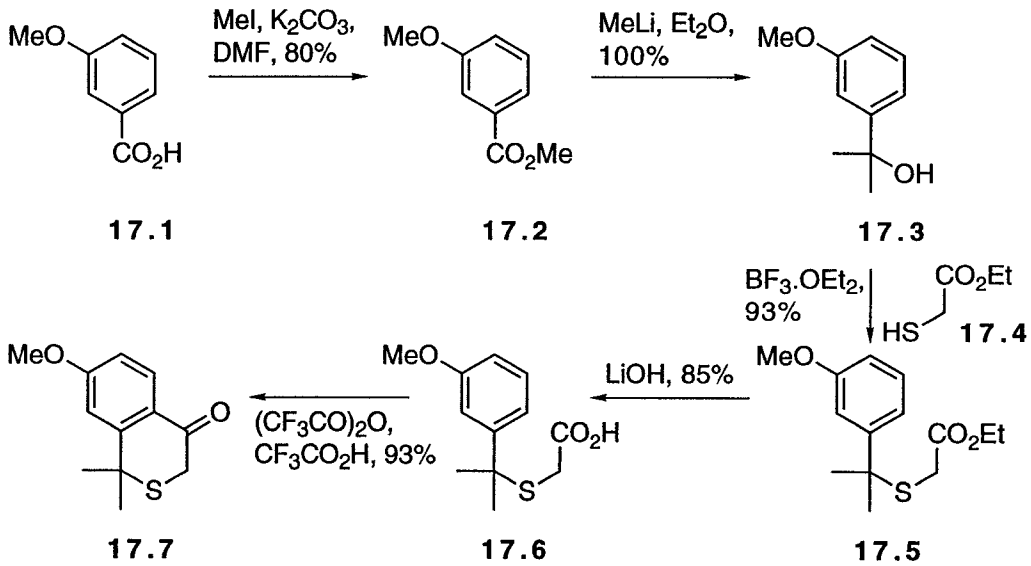
**Scheme 16**

unsuccessful; had we obtained it, we would have used it with

boronic acid **15.1** in place of **15.2** (see Scheme 15). Before we had an opportunity to identify what had caused the preparation of **16.1** to fail in our hands, a successful route to compounds of type **1.1** was identified and so no further work was done with boronic acids.

**Cyclic sulfide approach**

Some of the problems we had encountered might have been caused by steric factors introduced by the *t*-BuS group, and we next sought to avoid such difficulties by incorporating the sulfur into a ring, as in **17.7** (Scheme 17).

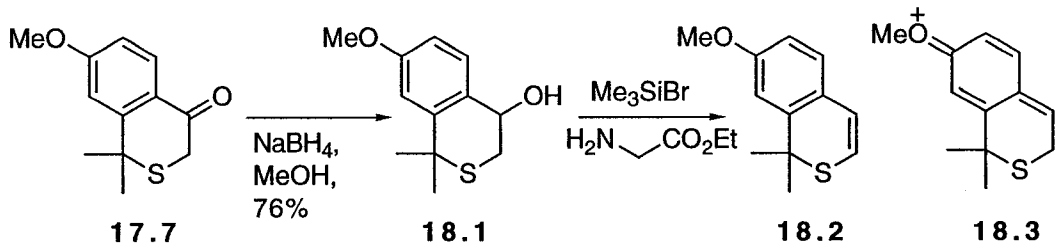


**Scheme 17**

*m*-Methoxybenzoic acid (**17.1**) was methylated (Scheme 17) and the resulting ester was converted into the tertiary alcohol **17.3** by the action of MeLi. Condensation with thiol ester **17.4**,[21] mediated by $BF_3.OEt_2$, gave the sulfide **17.5**,

from which point ester hydrolysis and cyclization afforded the desired ketone **17.7**. All the yields in this sequence were high.

With ketone **17.7** in hand, we tried to form an imine with (±)-$H_2NCHMeCO_2Et$ (PhH, $TsOH.H_2O$, heat), but no reaction occurred.

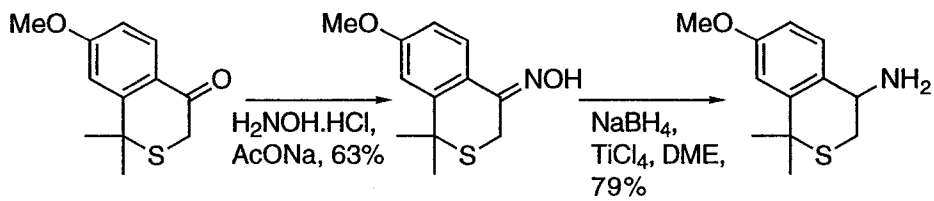


**17.7** **18.1** **18.2** **18.3**

**Scheme 18**

Reduction of ketone **17.7** ($NaBH_4$, MeOH, 76%) gave alcohol **18.1**. This was treated with $Me_3SiBr$ and $H_2NCH_2CO_2Et$ with the intention of generating the corresponding bromide or a quinone methide intermediate (see **18.3**); either species would then be trapped by the amine. In the event, however, the experiment gave **18.2**.

Ketone **17.7** was readily converted into oxime **19.1**, and reduction with $NaBH_4$-$TiCl_4$[22] gave amine **19.2**, which we planned to use for displacement of halogen from chiral α-

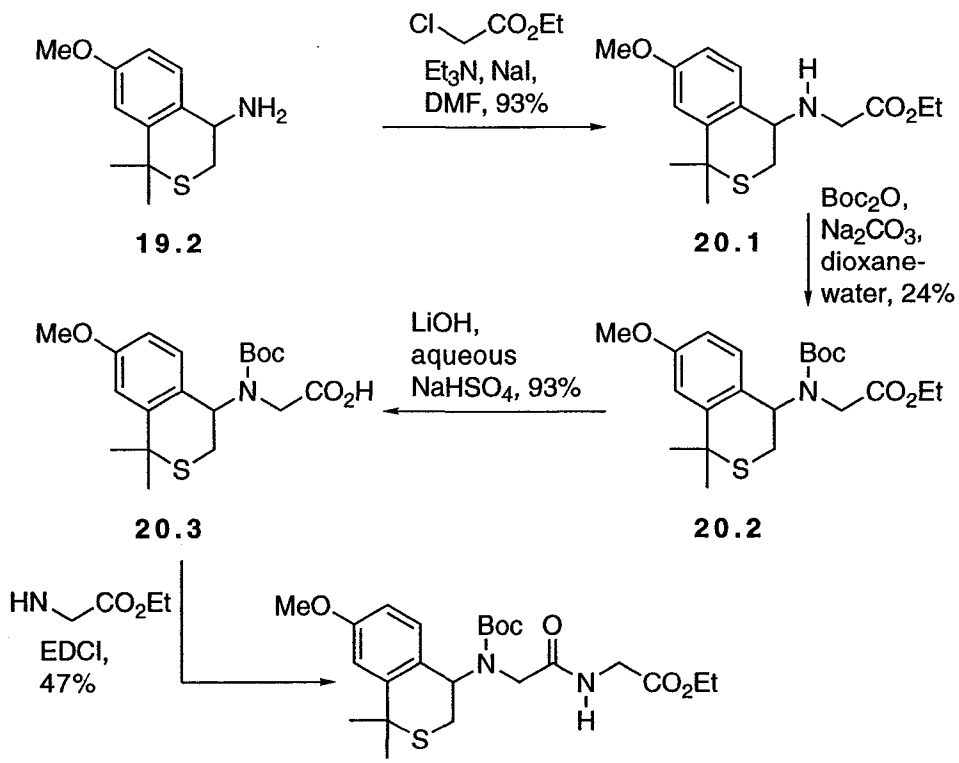


**17.7** **19.1** **19.2**

**Scheme 19**

bromo esters – a process closely related to Kent's approach.[23]

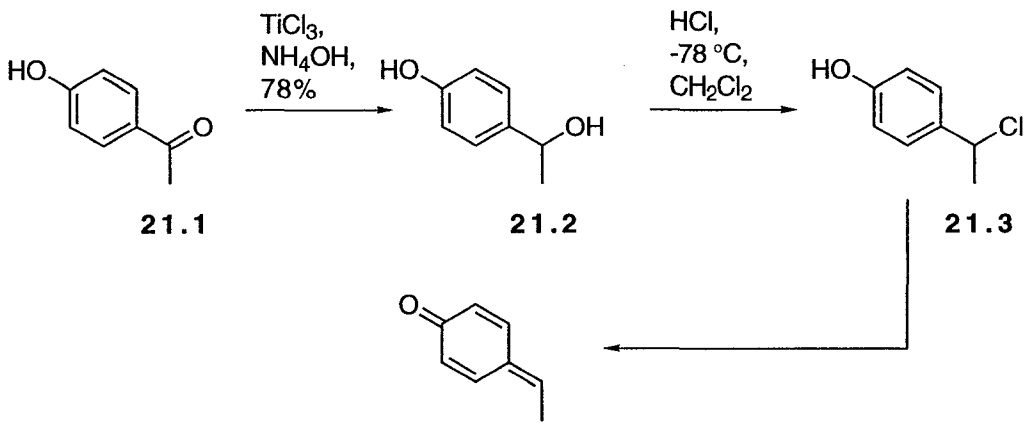
Amine **19.2** reacted readily with $ClCH_2CO_2Et$ to give **20.1** (Scheme 20). Protection of the nitrogen as a carbamate and selective hydrolysis of the ethyl ester took the route to **20.3**, at which point we coupled the acid with $H_2NCH_2CO_2Et$. The next task was to release a thiol group in **20.4**. This step was tried with the simple model **20.1**. Surprisingly, the compound was stable to the standard conditions [$Hg(OAc)_2$, $CF_3CO_2H$] even with a prolonged reaction time (2 days). Consequently, this route was abandoned.



**Scheme 20**

**Quinone methide and related approaches – a successful route**

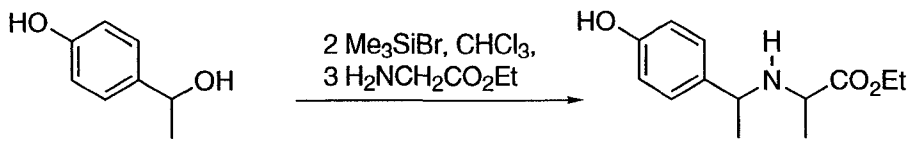
We decided at this point to investigate the possibility of adding an amine (as in $H_2NCH_2CO_2R$) to a quinone methide and, in the event, this approach led to an acceptable route to our target compounds of type **1.1**.



**21.1** **21.2** **21.3** **21.4**

**Scheme 21**

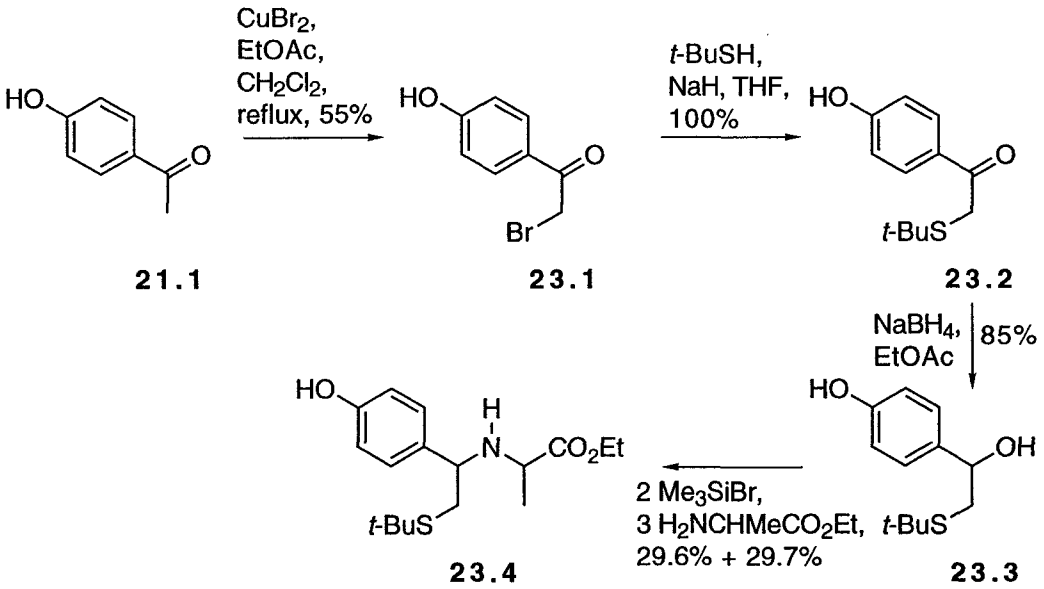
The quinone methide **21.4** has been prepared, but not isolated from its solution.[24] We reduced ketone **21.1** to alcohol **21.2** using $TiCl_3$ in $NH_4OH$-MeOH.[25] Use of $NaBH_4$ failed to give **21.2**. With **21.2** in hand, treatment with HCl and then with $Et_3N$, as reported in the literature,[24] gave a solution of **21.4**, but removal of the solvent resulted in decomposition. Accordingly, we decided to generate the quinone methide *in situ*. It was more convenient for us to make the bromide corresponding to **21.3** (by using $Me_3SiBr$[26]), and we also decided to employ an excess of amine[27] to effect elimination of HBr. Treatment of **21.2** in dry $CHCl_3$ with 2



**21.2** **22.1**

**Scheme 22**

equivalents of $Me_3SiBr$ (there are 2 hydroxyl groups in **21.2**), followed by addition of 3 equivalents[28] of (±)-$H_2NCHMeCO_2Et$ gave **22.1**. Based on this promising result, we then set out to try a similar reaction with a protected sulfur unit in place.



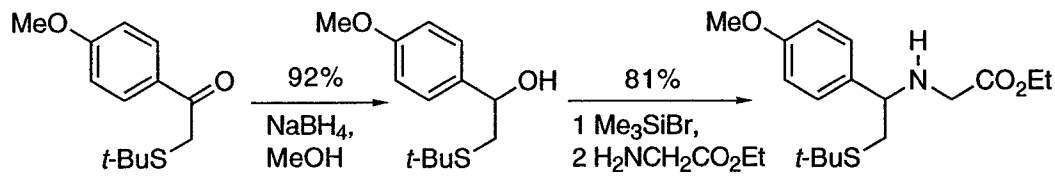
**21.1** **23.1** **23.2** **23.3** **23.4**

**Scheme 23**

Phenolic ketone **21.1** was converted into bromide **23.1**[29] by the action of $CuBr_2$, as described in the literature (Scheme 23). Displacement of bromide with *t*-BuSNa and reduction ($NaBH_4$) gave the required alcohol **23.3**. When this was treated with 2 equivalents of $Me_3SiBr$ and 3 equivalents

of (±)-$H_2NCHMeCO_2Et$ the desired amine **23.4** was obtained as a separable mixture of diastereoisomers.

During the optimization of this reaction it was noticed that the use of only 1 equivalent of $Me_3SiBr$ and 2 equivalents of (±)-$H_2NCHMeCO_2Et$ was just as effective as the use of 2 and 3 equivalents, respectively. This suggested that the reaction might not occur through a quinone methide (which would require 3 equivalents of amine), and for this reason, we examined the methoxy series, as summarized in Scheme 24. When only 1 equivalent of



**3.3** **24.1** **24.2**

**Scheme 24**

$H_2NCH_2CO_2Et$ was used, together with 1 equivalent of a sacrificial base (*i*-$Pr_2NEt$), a lower yield (ca 37%) of **24.2** was obtained.

Surprisingly, in the reactions with $Me_3SiBr$ neighboring group participation by the sulfur with loss of the *t*-butyl group does not occur.

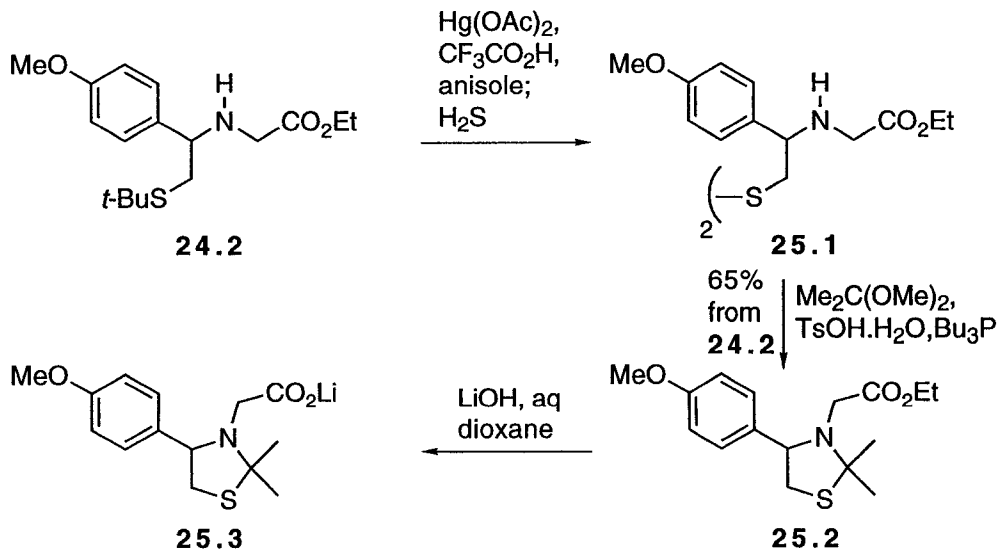
With a method for making compounds of type **24.2** in hand, we considered a number of procedures for protection of the nitrogen and sulfur atoms and the carboxyl group.

**Studies on nitrogen and sulfur protection**

We first investigated the possibility of protecting the nitrogen and sulfur in such a way that *both* heteroatoms could be deprotected in a single step, after our derivatized amino acid (cf. **1.1**) had been incorporated as the *N*-terminus of a peptide segment.

**Thiazolidine route for simultaneous protection of nitrogen and sulfur**

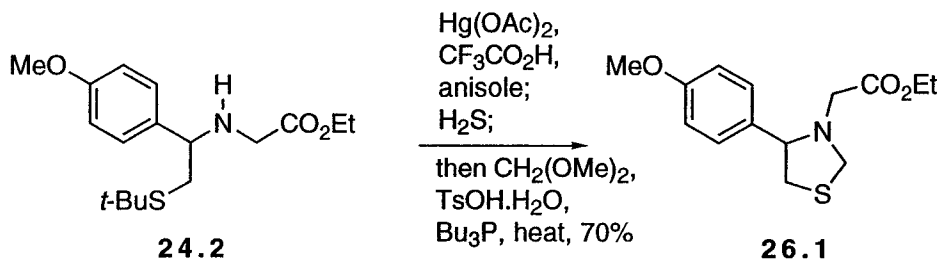
Treatment of **24.2** with $Hg(OAc)_2$ in $CF_3CO_2H$ containing $7.5^{v}/_{v}\%$ anisole, followed by addition of $H_2S$, and exposure to air gave **25.1**. This was converted into the thiazolidine **25.2** by heating in $Me_2C(OMe)_2$ in the presence of $TsOH.H_2O$ and $Bu_3P$ – the latter added in order to reduce the disulfide. Hydrolysis of the ester group with LiOH produced the lithium salt **25.3**, but he free carboxylic acid could not be obtained



**Scheme 25**

by acidification to pH 2-3, and we gained the impression that in the carboxylic acid form the heterocycle is very acid-sensitive.

The lithium salt did not form an amide on attempted coupling with $BnNH_2$ in the presence of EDCI.[30] When the lithium salt was quenched with 1 equivalent of HCl, treatment with $BnNH_2$ and EDCI again failed to give the coupled amide. We therefore examined an unsubstituted thiazolidine in the expectation that it would be more acid-stable. Accordingly, the



**24.2** **26.1**

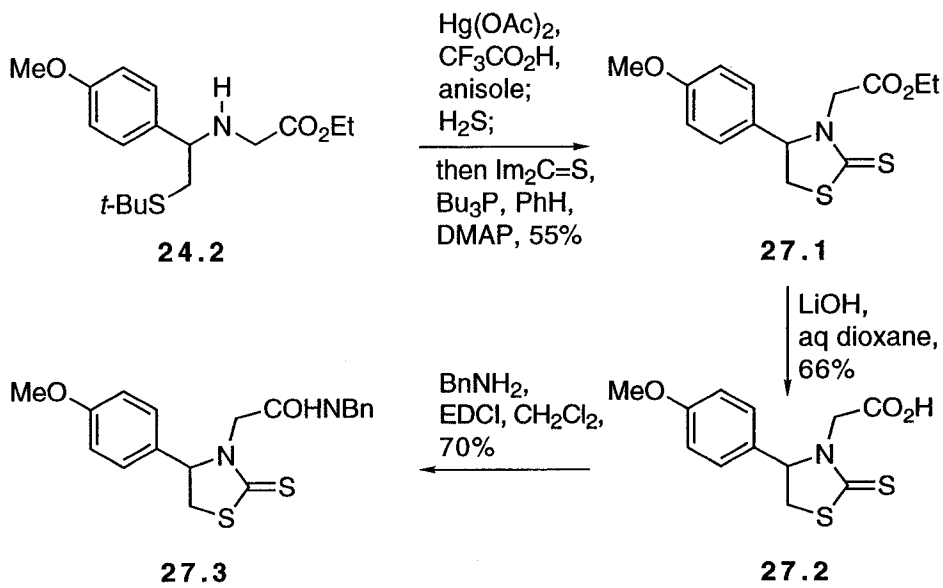
**Scheme 26**

*t*-butyl group of **24.2** was removed in the usual way and the crude product was converted into the thiazolidine **26.1** by using $CH_2(OMe)_2$ under conditions of acid catalysis. Hydrolysis of the ester with LiOH in aqueous dioxane resulted in opening of the heterocycle, even without acidification.

**Thiocarbamate route for simultaneous protection of nitrogen and sulfur**

Deprotection of sulfur in **24.2** and reaction with $Im_2C=S$ gave the thiocarbamate **27.1** in 55% yield. Hydrolysis of the

ester and coupling with $BnNH_2$ (EDCI) gave **27.3**. At this point we were not able to deprotect the nitrogen and sulfur. Treatment with $Hg(OAc)_2$ in aqueous MeCN led to recovery of

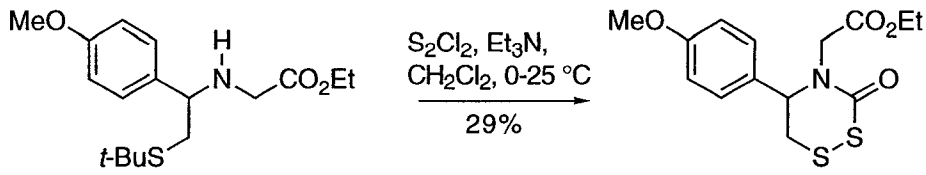


**Scheme 27**

starting material, and use of $Hg(OAc)_2$ in $CF_3CO_2H$ gave a product that was not properly characterized, but which is probably the C=O analog of **27.3** ([C=O instead of C=S), based on slight chemical shift differences between **27.3** and the new compound.

**Dithiocarbamoyl route for simultaneous protection of nitrogen and sulfur**

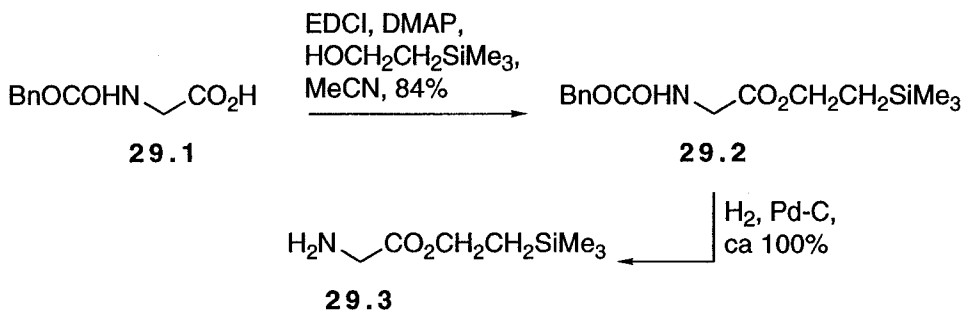
Compound **24.2** reacted with $S_2Cl_2$ to give **28.1** (Scheme 28), but exposure to LiOH produced a complex mixture. Clearly, **28.1** is too sensitive to base, and so we prepared the corresponding β-(trimethylsilyl)ethyl ester with the



**24.2** **28.1**

**Scheme 28**

intention of removing the ester group by the action of fluoride ion.[31]

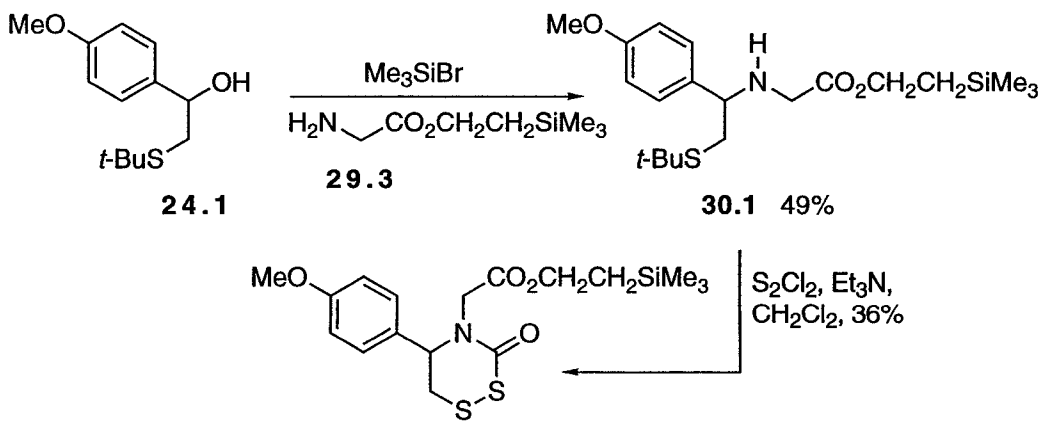


**29.1** **29.2**

**29.3**

**Scheme 29**

The requisite ester **29.3**[32] was made in the straightforward way summarized in Scheme 29 by coupling



**24.1** **29.3** **30.1** 49%

**30.2**

**Scheme 30**

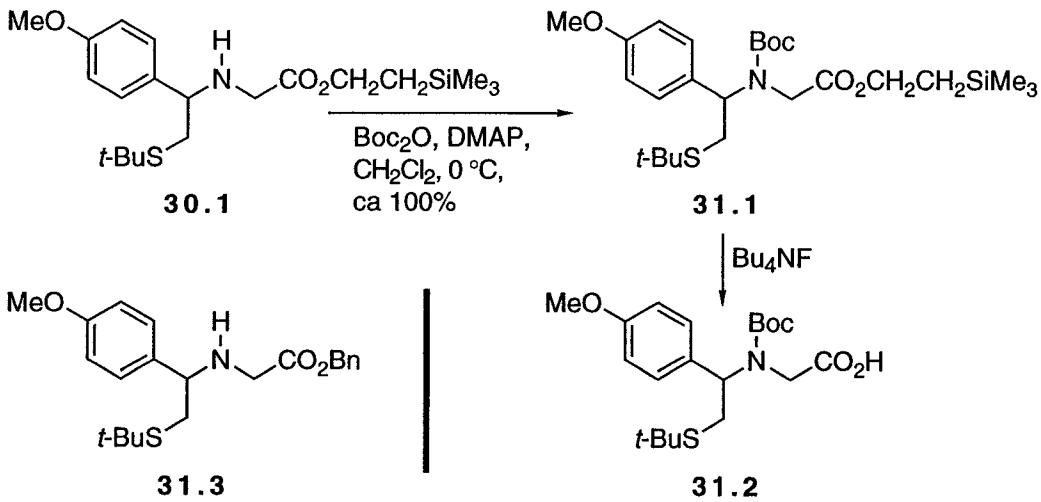
$BnOCOHNCH_2CO_2H$[33] with $HOCH_2CH_2SiMe_3$,[21] and deprotecting the nitrogen. The compound dimerizes even when stored at -20 °C and so freshly prepared material must be used.

Alcohol **24.2** was then treated with $Me_3SiBr$ (1 equivalent) and 2 equivalents of **29.3** to obtain **30.1** (49%). Reaction with $S_2Cl_2$ gave **30.2**, but this produced a complex mixture when treated with $Bu_4NF$.

At this stage attempts to protect both nitrogen and sulfur simultaneously were abandoned.

**Carboxyl protection as a β-(trimethylsilyl)ethyl ester**

Ester **30.1** was protected on nitrogen, using $Boc_2O$ to form **31.2** (Scheme 31) in almost quantitative yield.

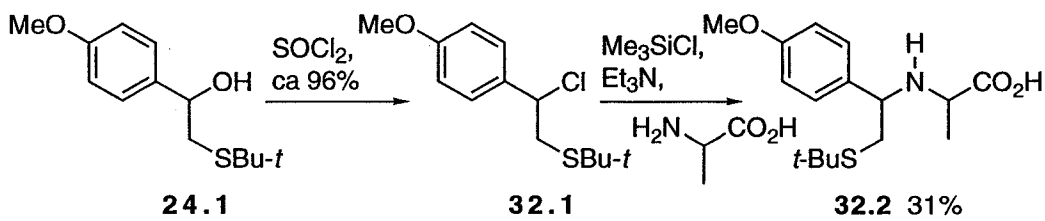


**Scheme 31**

Treatment with $Bu_4NF$ appeared ($^1H$ NMR) to give the desired acid **31.2**, but the material decomposed on attempted chromatography.

The benzyl ester **31.3** (made in the same way as **30.1**) was recovered unchanged on attempted hydrogenolysis ($H_2$, Pd-C or Pd-$BaSO_4$, EtOH), and so we decided to examine the trichloroethyl ester series. However, **24.1** did not afford the desired amine when treated with $Me_3SiBr$ and $H_2NCH_2CO_2CH_2CCl_3$.[34]

We eventually settled on the ethyl ester for glycine and the *t*-butyl ester for alanine and serine – the three amino acids we investigated in our work. Use of a base with esters other than glycine might cause epimerization; *t*-butyl esters can be hydrolyzed under acidic conditions and are resistant to nucleophilic attack. We did, however, examine briefly the possibility of avoiding carboxyl protection altogether (Scheme 32). To this end, alcohol **24.1** was converted into its chloride, which was then treated with the silyl ester formed by refluxing a chloroform solution of $Me_3SiCl$, (±)-alanine, and $Et_3N$.[35] This procedure gave **32.2**, after aqueous acidic workup. Although we do obtain the desired product we decided not to use this route because of the long reaction time in the presence of the organic base; this might compromise the stereochemical integrity of the amino acid – a feature that was not examined in this experiment.



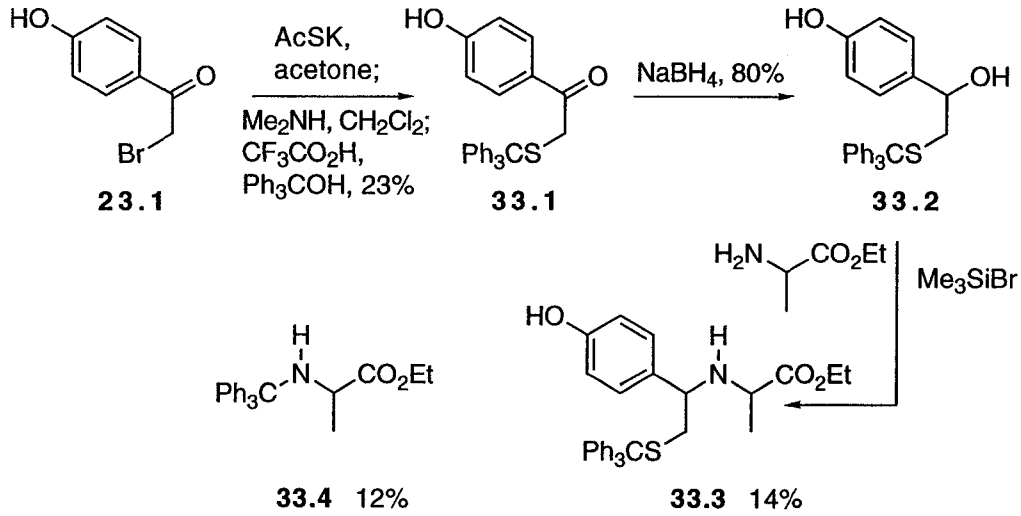
**24.1** **32.1** **32.2** 31%

**Scheme 32**

**Sulfur protection**

Besides the *t*-butyl group, we also examined two other methods for protecting the sulfur.

Before we had settled on methoxy substitution of the benzene ring, the *S*-trityl series shown in Scheme 33 was examined. Bromide **23.1** was converted by the standard reactions shown into the *S*-trityl ketone **33.1**. Reduction gave alcohol **33.2**, and this was coupled by our $Me_3SiBr$ method with (±)-$H_2NCHMeCO_2Et$. Although he desired trityl-protected derivative **33.3** was obtained, the yield was low; there was appreciable transfer of the trityl group to nitrogen, and



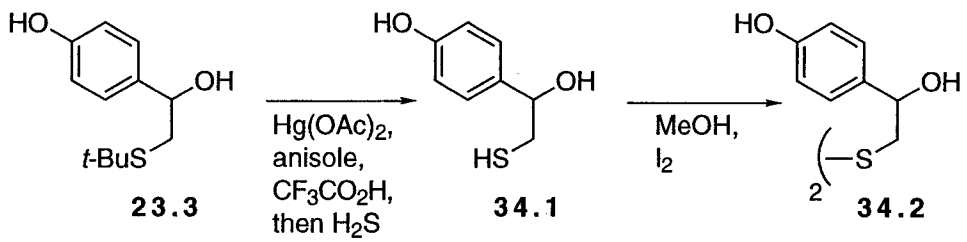
**Scheme 33**

compound **33.4** was isolated in 12% yield.

We also took alcohol **23.3**, removed the *t*-butyl group (**23.3** → **34.1**) and oxidized the product to its disulfide **34.2**, but this substance failed to undergo coupling with (±)-$H_2NCHMeCO_2Et$ in the presence of $Me_3SiBr$.

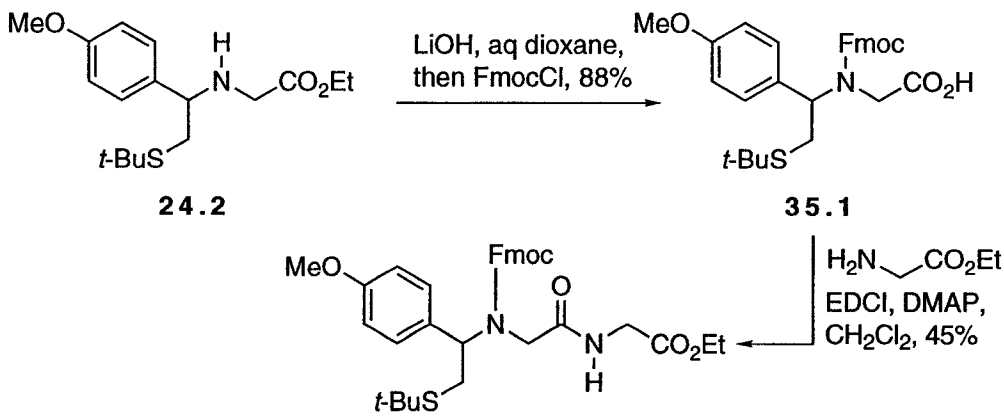
**Nitrogen protection**

The derivatized amino acid **24.2** was hydrolyzed with LiOH in aqueous dioxane and the mixture was quenched by addition



**Scheme 34**

of FmocCl to obtain **35.1** in 88% yield. The acid was then coupled with $H_2NCH_2CO_2Et$, but an attempt to remove the Fmoc group from the product (**35.2**) by treatment with $Et_2NH$ gave

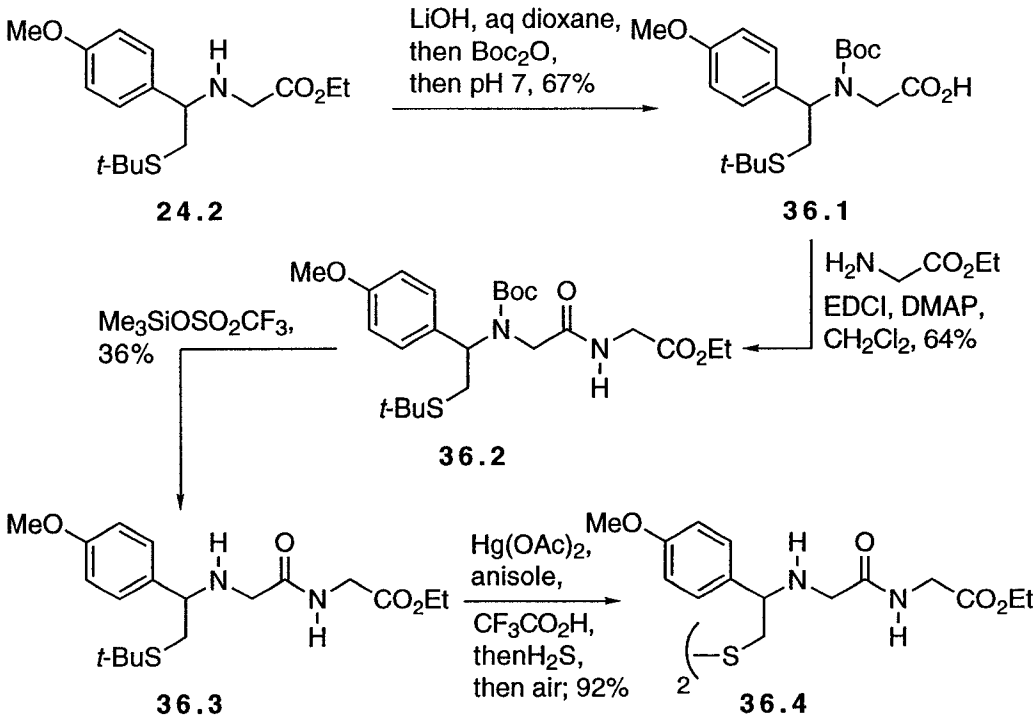


**Scheme 35**

unidentified products. A similar sequence was performed using $Boc_2O$ instead of FmocCl (Scheme 36).

The *N*-Boc acid **36.1**, could not be purified by flash chromatography, although a cyclohexylamine salt could be

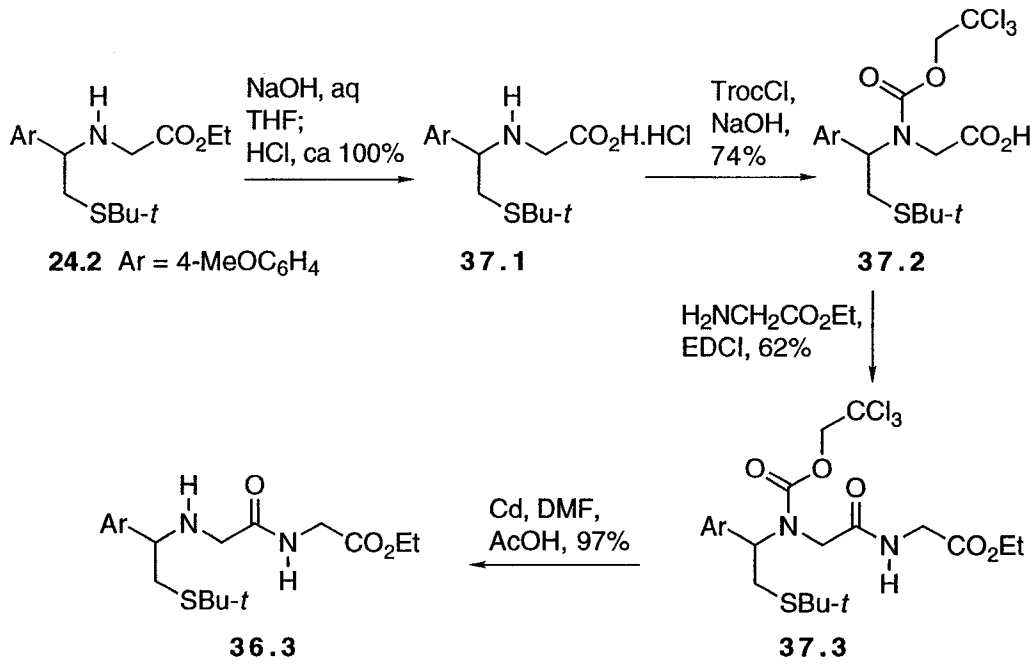
made. Coupling with $H_2NCH_2CO_2Et$ gave **36.2**. Removal of the *N*-Boc group required extensive experimentation,[36] until we tried $Me_3SiOSO_2CF_3$, an experiment that gave the expected amine



**Scheme 36**

**36.3**. Removal of the *S*-protecting group and oxidation, best done by exposure to air rather than by use of $I_2$-MeOH, gave disulfide **36.4**. Because of the low yield in the removal of the Boc group we subsequently used Troc [trichloroethyl carbamate, $Cl_3CCH_2OC(O)$] protection (Scheme 37).

Ester **24.2** was hydrolyzed with aqueous base, and the nitrogen was protected as its Troc carbamate under standard conditions.[37] Coupling with $H_2NCH_2CO_2Et$ gave **37.3** and the Troc group was removed with Cd in DMF-AcOH.[38] As described above (Scheme 36), the sulfur protecting group of compound

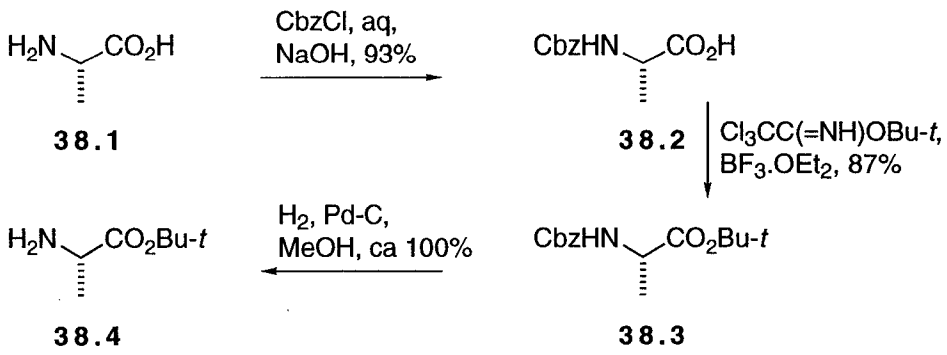


**Scheme 37**

**36.3** can be removed efficiently. The yields in this sequence were acceptable and the route represents our optimized version of making a specially derivatized glycine of the type **1.1**. Coupling of **37.2** with $H_2NCH_2CO_2Et$ was done in order to show that deprotection of both nitrogen and sulfur could be accomplished in a situation that resembles the one that would be present when the derivatized amino acid is the *N*-terminus of a peptide.

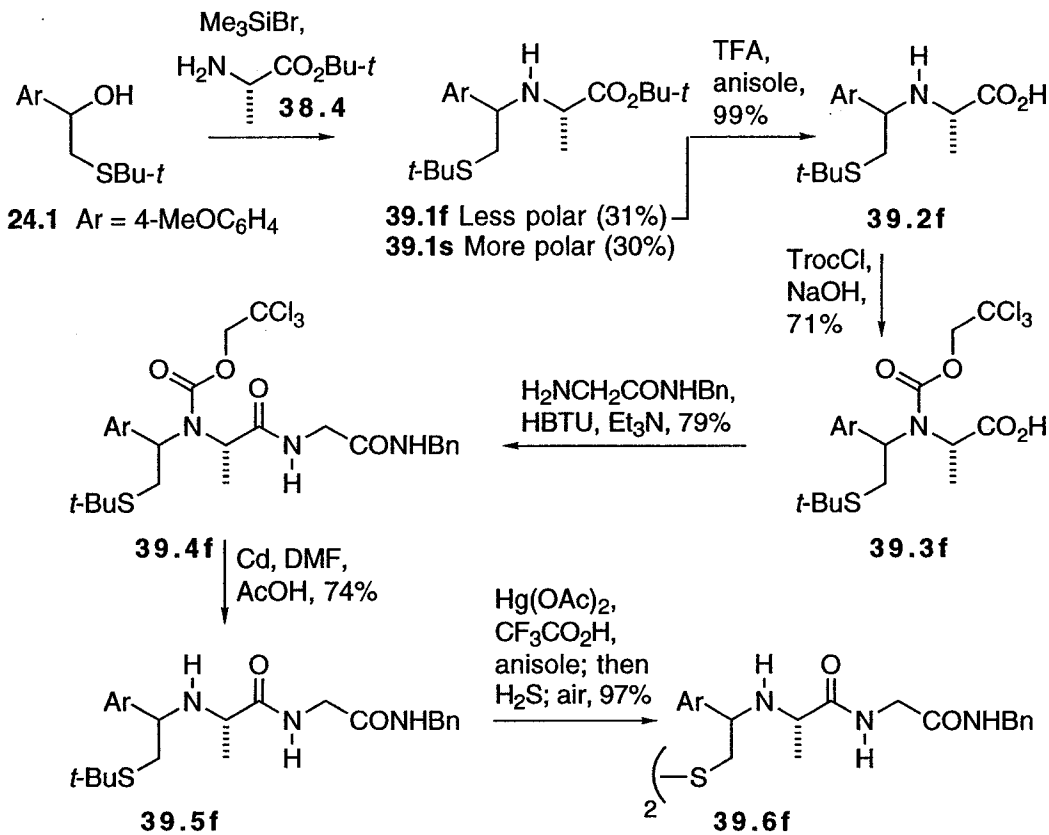
We next repeated the sequence using L-alanine, for which we needed L-alanine *t*-butyl ester (**38.4**). The preparation of this known ester[39,40] was initially troublesome, but we eventually found a route that gives the product without epimerization (Scheme 38).

L-Alanine was protected as its Cbz carbamate (**38.2**),[33]



**Scheme 38**

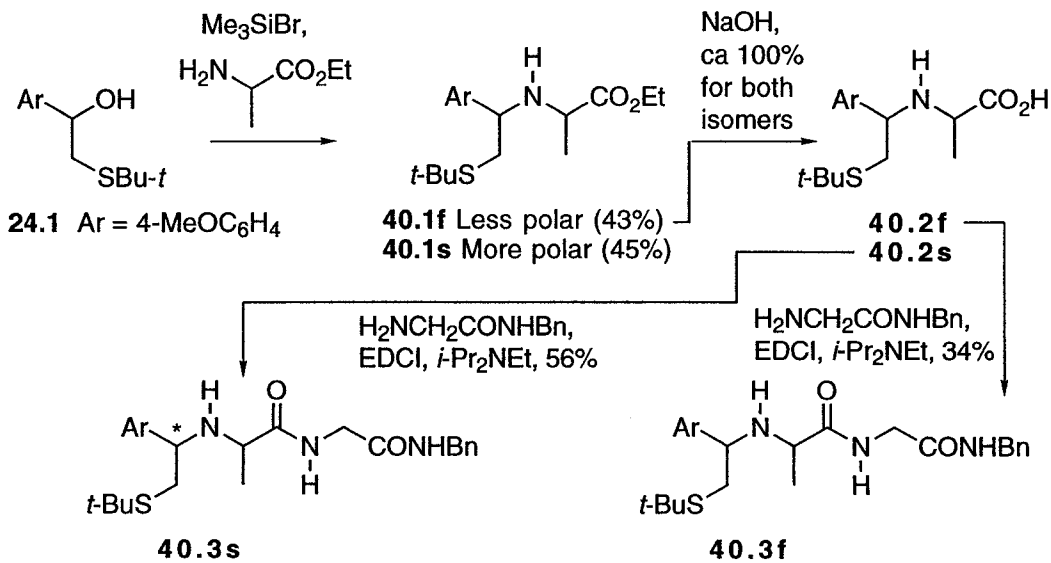
and the *t*-butyl ester **38.3** was prepared using the *t*-butyl trichloroacetimidate reagent.[41] Hydrogenolysis then gave L-alanine *t*-butyl ester (**38.4**). The Mosher amide was prepared and found to give a single peak in the $^{19}F$ NMR spectrum. In



**Scheme 39**

this case we did not examine the Mosher amides of racemic material but we did so later on when we investigated the serine series.

Alcohol **24.1** was coupled with the L-alanine *t*-butyl ester **38.4** under our optimized conditions to afford a separable mixture of the less polar (**39.1f**, 31%) and more polar (**39.1s**, 30%) adducts, respectively. The less polar isomer was hydrolyzed and protected by treatment with TrocCl (71%) and then coupled with $H_2NCH_2CONHBn$. Removal of the Troc protecting group (Cd, DMF, AcOH, 74%) and deprotection of the sulfur [$Hg(OAc)_2$, $CF_3CO_2H$, anisole, $H_2S$), followed by aerial oxidation, gave the expected disulfide **39.6f**. Compound **39.5f** has been sent to Boehringer Ingelheim (Laval) together with a sample made from racemic alanine for examination on a chiral column. We hope that the chromatographic tests will show that **39.5f** is a single enantiomer. The material made

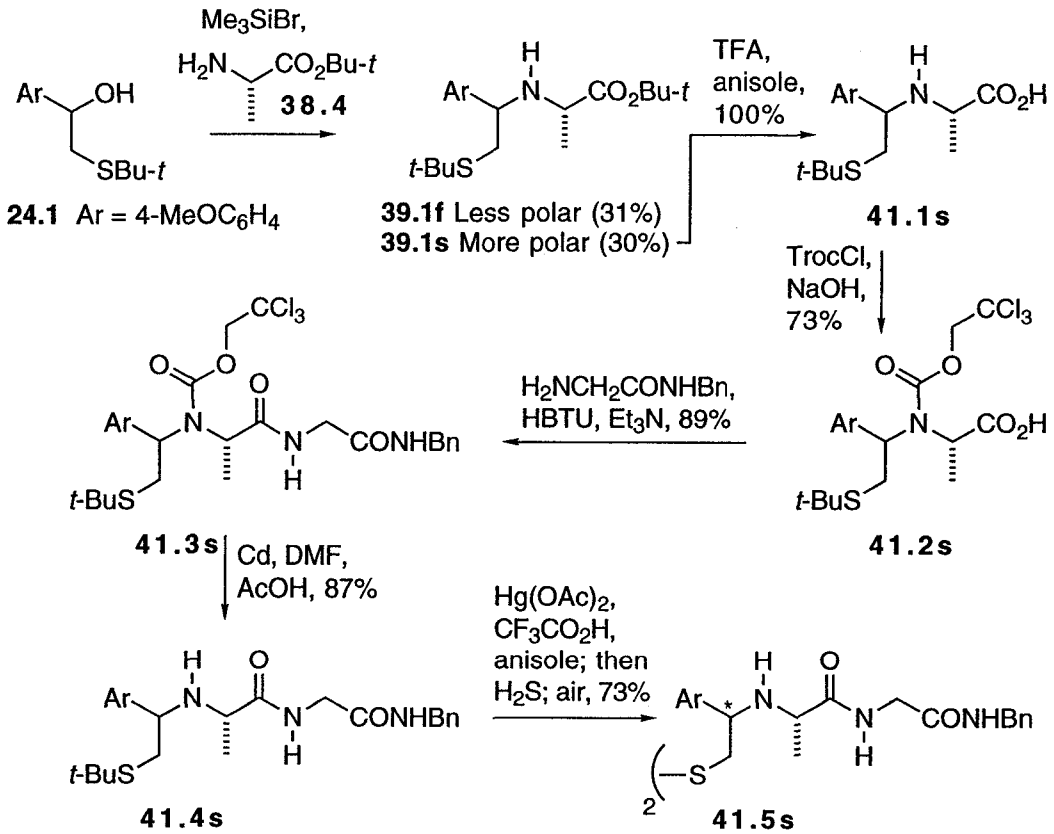


**Scheme 40**

from racemic alanine was prepared as summarized in Scheme 40. Again a more polar (**40.3s**) and a less polar (**40.3f**) isomer were obtained, differing in stereochemistry at the starred atom.

It should be noted that in the above sequence the nitrogen was not protected as a carbamate; evidently, the bulky benzylic substituent served as a protecting group. However, if the reactions were to be repeated with optically active alanine ethyl ester, carbamate protection would probably be necessary in order to prevent epimerization.

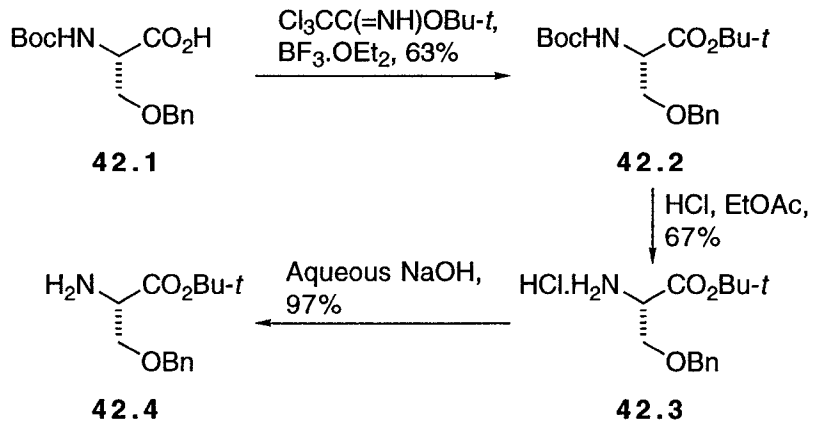
The same series of reactions used with the less polar isomer **39.1f** was carried out with the more polar isomer



**Scheme 41**

**39.1s** to give a final product (**41.5s**) that should differ from **39.6f** only in the stereochemistry at the starred atom.

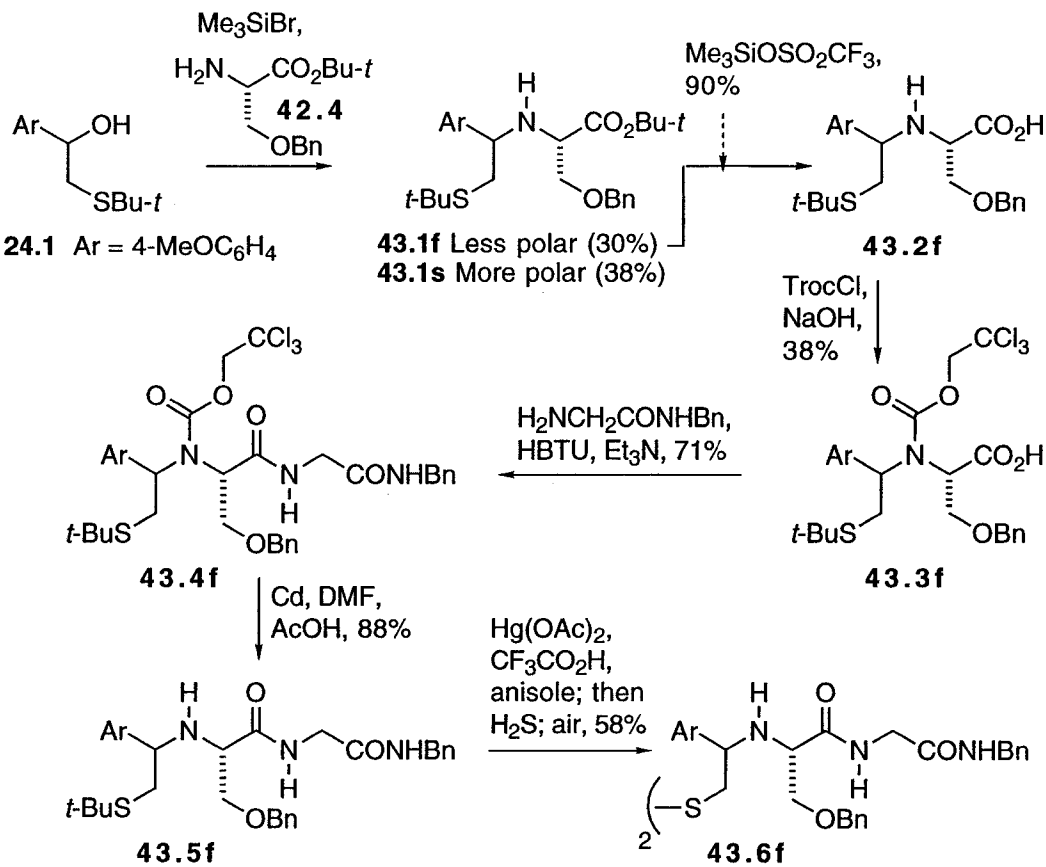
Finally, we decided to study an example of an amino acid with a functionalized side chain, and we chose L-serine as a suitable representative of this class. The required starting material was *O*-benzyl L-serine *t*-butyl ester (**42.4**). Although this is a known compound,[40] several of the literature methods we examined for making it caused extensive epimerization in the step in which the acid was converted[42] into its *t*-butyl ester. We eventually found that the route shown in Scheme 42 is satisfactory.



**Scheme 42**

*N*-Boc *O*-benzyl L-serine[43] could be converted into its *t*-butyl ester **42.2** by the action of *t*-butyl trichloroacetimidate[41] Removal of the Boc group with HCl in EtOAc took place without disturbing the ester, and the free amine (**42.4**) was obtained from the hydrochloride salt by treatment with NaOH. However, the HCl treatment should not be extended beyond 14 h; material obtained at that time (30%)

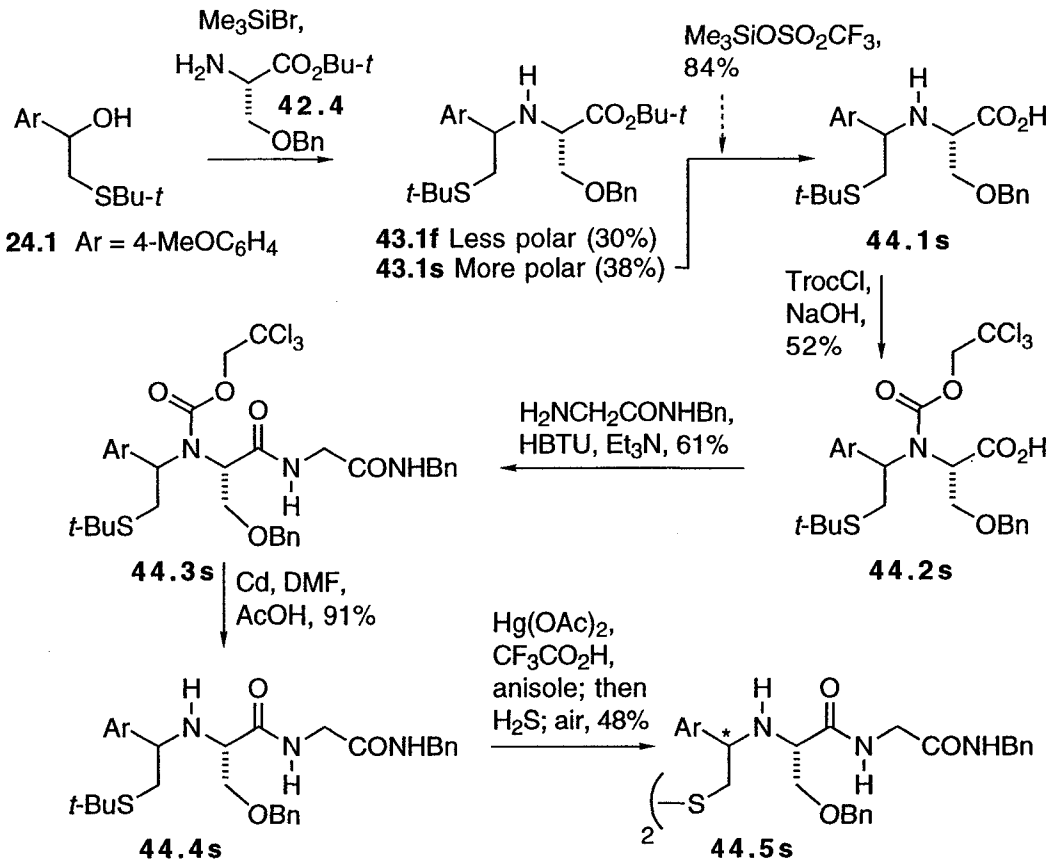
has an ee of 97%, as judged by $^{19}F$ NMR measurements on the derived Mosher amide. An additional crop obtained after 36 h (23%) had an ee of 57%. Of course, we used the higher quality batch for subsequent experiments.



**Scheme 43**

The serine derivative **42.4** was subjected to the series of reactions shown in Scheme 43 and Scheme 44; the reactions are identical to those used for L-alanine, except for the fact that the *t*-butyl ester unit was deprotected with $Me_3SiOSO_2CF_3$, since $CF_3CO_2H$ caused cleavage of the benzylic C-N bond. We have not submitted any of the compounds in this serine series for examination by chiral HPLC.

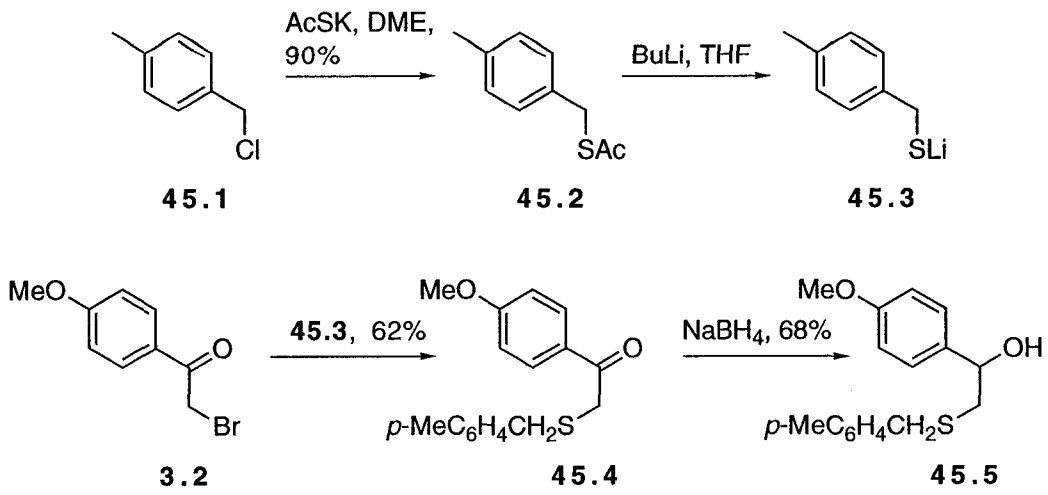
In order to show additional generality of our method we decided to make compound **46.5**, which has the same sulfur protecting group that was used by Kent[23] and by Dawson[44] in their bromide displacement method.[23] *p*-Methyl benzyl chloride



**Scheme 44**

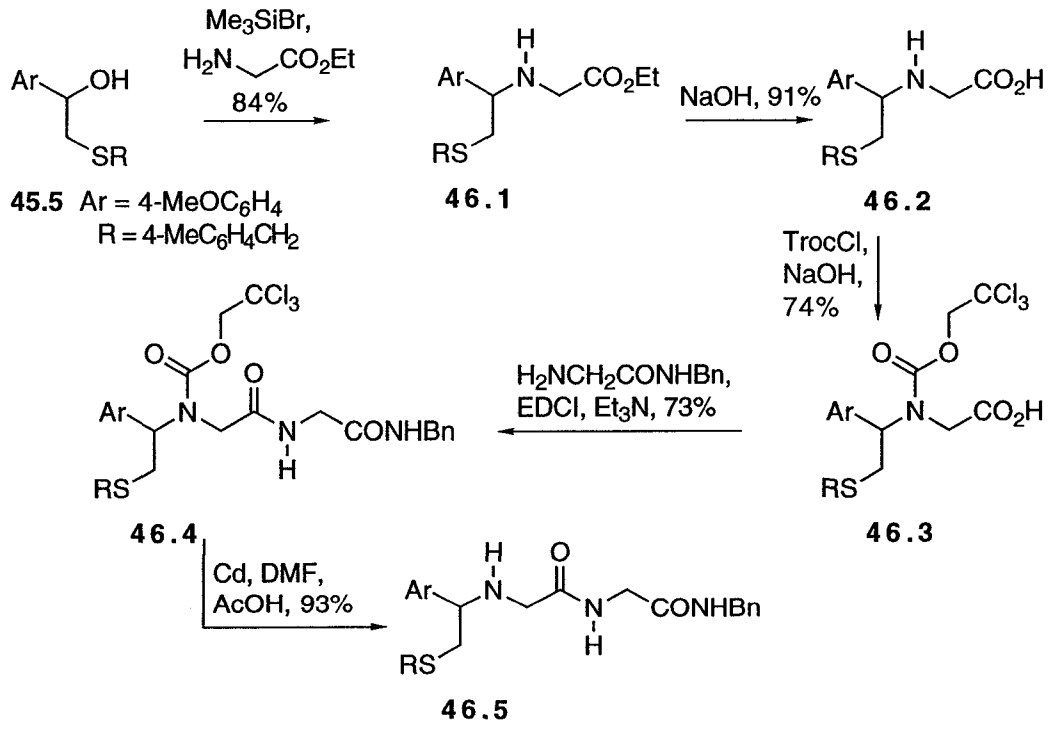
(**45.1**) was converted into thioacetate **45.2**, and treatment with BuLi gave the thiolate **45.3**. This was alkylated with bromide **3.2**, and, finally, reduction gave alcohol **45.5**.

The alcohol **45.5** was treated with $H_2NCH_2CO_2Et$ and $Me_3SiBr$, according to our general procedure, and the product **46.1** was hydrolyzed and protected on nitrogen with TrocCl.



**Scheme 45**

Coupling in the usual way with $H_2NCH_2CONHBn$ and removal of the Troc group gave **46.5**. The protecting group from compounds of this type has been removed with HF.[23] Our procedure clearly



**Scheme 46**

tolerates at least minor changes in the sulfur protecting group.

**Conclusion**

Our method for making derivatized amino acids of type **1.1** provides an alternative to the bromide displacement route reported by Kent,[23] and has been shown to work with an amino acid having a functionalized side chain, although at the time of writing the stereochemical purity of several compounds has not yet been established. The availability of the derivatized amino acids should be helpful in studies on conformational or steric factors in the derivatizing unit that facilitate or hinder ligation and acyl transfer for different amino acids.

Further studies should include attempts to carry out ligation and acyl transfer with short peptide thioesters, using compounds such as **36.4**, **39.6f**, **41.5s**, **43.6f**, and **44.5s**. Other amino acids should be similarly derivatized and examined in the ligation-acyl transfer sequence. Such studies would identify those amino acids at the ligation site for which the sequence works properly, and those for which acyl transfer is too slow to be useful.

## EXPERIMENTAL SECTION

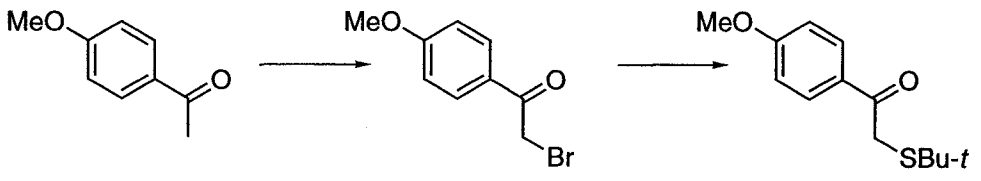
**Note:** Some of the compounds in this section were not fully characterized as the work was highly exploratory; only those that appeared to lead in the desired direction were fully characterized.

### General procedures

Unless stated to the contrary, the procedures described in the Experimental Section of Chapter 1 of this thesis were followed. Optical rotations were measured at 20 °C with a Perkin Elmer 241 Polarimeter, using a sodium lamp.

Compound number **XXf** stands for compound **XX**, faster moving isomer on tlc plates; **XXs** stand for slower moving isomer. The f or s designation in all experiments will indicate whether a particular compound originates from the chromatographically faster- or slower-running series, as determined from the earliest point at which separation of isomers was possible.

### 2-*tert*-Butylsulfanyl-1-(4-methoxyphenyl)ethanone (3.3).

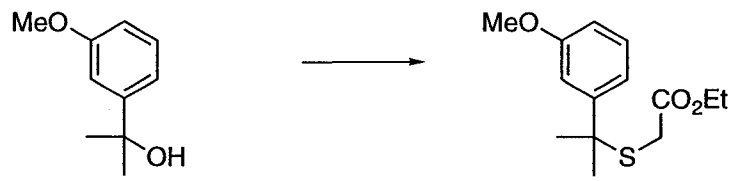


**3.1** **3.2** **3.3**

$Br_2$ (300 μL, 5.77 mmol) was added dropwise over 10 min to a stirred and warmed (40 °C) solution of 4-methoxyacetophenone (**3.1**) (867 mg, 5.77 mmol) in bench $CHCl_3$ (10 mL). At the end of the addition the mixture was diluted with $Et_2O$ (100 mL), washed with saturated aqueous $NaHCO_3$, dried ($MgSO_4$) and evaporated to give bromide **3.2** (1.24 g, 93%) as a white solid, which was used for the next step without purification.

A solution of the above bromide (8.82 g, 38.5 mmol) in dry THF (40 mL) was added dropwise over 10 minutes to a stirred and cooled (0 °C) solution of *t*-BuSLi [made by slow addition of *n*-BuLi (2.5 M in hexanes, 17.7 mL, 44.3 mmol) to a stirred and cooled (0 °C) solution of *t*-BuSH (5.21 mL, 46.2 mmol)] in dry THF (100 mL), the solution being stirred for 2.5 h before use]. When addition was complete the cold bath was removed and stirring was continued overnight. The mixture was diluted with $Et_2O$ (200 mL), washed thoroughly with water (3 x 100 mL), dried ($MgSO_4$) and evaporated. Flash chromatography of the residue over silica gel, using 1:6 EtOAc-hexanes, gave **3.3** (9.05 g, 98%) as a colorless oil: FTIR ($CDCl_3$, cast) 1670 $cm^{-1}$; $^1H$ NMR ($CDCl_3$, 500 MHz) δ 1.34 (s, 9 H), 3.81 (s, 2 H), 3.85 (s, 3 H), 6.88-6.90 (m, 2 H), 7.89-7.91 (m, 2 H); $^{13}C$ NMR ($CDCl_3$, 125 MHz) δ 30.7 (q' ), 35.5 (t'), 43.6 (s'), 55.4 (q'), 113.8 (d'), 128.7 (s'), 131.1 (d'), 163.6 (s'), 194.9 (s'); exact mass *m/z* calcd for $C_{13}H_{18}O_2S$ 238.1027, found 238.1027.

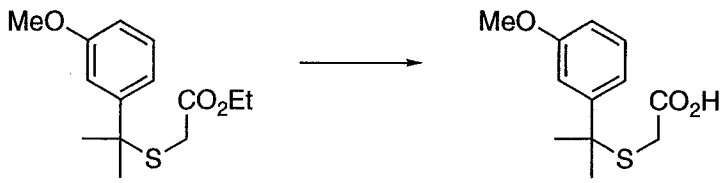
**[1-(3-Methoxyphenyl)-1-methylethylsulfanyl]acetic Acid Ethyl Ester (17.5).**



**17.3** **17.5**

$BF_3.OEt_2$ (42 μL, 0.33 mmol) was added to a stirred and cooled (-78 °C) solution of alcohol **17.3** (50 mg, 0.30 mmol) in dry $CH_2Cl_2$ (1.5 mL). After 20 min, neat $EtO_2CCH_2SH$ (37 μL, 0.33 mmol) was injected in one portion and the cold bath removed. Stirring was continued for 40 min, by which time all the starting materials were consumed (tlc control, silica, 1:3 EtOAc-hexane). The mixture was diluted with $Et_20$ (15 mL), washed with water (2 x 5 mL), dried ($MgSO_4$) and evaporated. Flash chromatography of the residue over silica gel (2 x 20 cm), using 1:6 EtOAc-hexanes, gave **17.5** (75.8 mg, 93%) as a colorless oil: FTIR ($CDCl_3$ cast) 1734 $cm^{-1}$; $^1H$ NMR ($CDCl_3$, 300 MHz) δ 1.17 (t, *J* = 7.1 Hz, 3 H), 1.68 (s, 6 H), 2.95 (s, 2 H), 3.78 (s, 3 H), 4.02 (q, *J* = 7.2 Hz, 2 H), 6.71-6.75 (m, 1 H), 7.05-7.09 (m, 2 H), 7.18-7.24 (m, 1 H); $^{13}C$ NMR ($CDCl_3$, 125 MHz) δ14.0 (q'), 30.1 (two overlapping q'), 32.6 (t'), 48.5 (s'), 55.2 (q'), 61.2 (t'), 111.7 (d'), 112.9 (d'), 118.9 (d'), 129.0 (d'), 147.1 (s'), 159.3 (s'), 170.4 (s'); exact mass *m/z* calcd for $C_{14}H_{20}O_3S$ 268.1133, found 268.1132.

**[1-(3-Methoxyphenyl)-1-methylethylsulfanyl]acetic Acid (17.6).**



**17.5** **17.6**

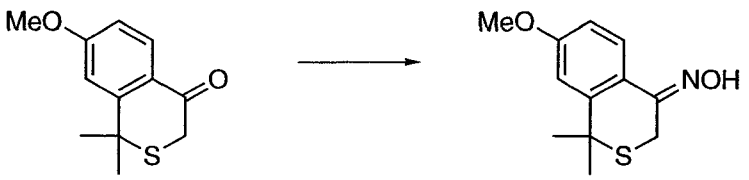
$LiOH.H_2O$ (3.71 g, 88.3 mmol) was added to a stirred solution of ester **17.5** (2.378 g, 8.83 mmol) in 1:1 water-THF (20 mL). After 5 h the mixture was washed with $Et_2O$ (2 x 20 mL) and the aqueous layer was acidified with concentrated hydrochloric acid. The resulting suspension was extracted with $Et_2O$ (3 x 20 mL) and the combined extracts were dried ($MgSO_4$) and evaporated. Flash chromatography of the residue over silica gel (2 x 20 cm), using 2:98 MeOH-$CH_2Cl_2$, gave **17.6** (1.19 g, 90%) as a colorless oil: FTIR ($CDCl_3$, cast) 3500-2600 (br), 1708 $cm^{-1}$; $^1H$ NMR ($CDCl_3$, 500 MHz) $\delta$ 1.70 (s, 6 H), 2.99 (s, 2 H), 3.78 (s, 3 H), 6.70-6.73 (m, 1 H), 7.04-7.07 (m, 2 H), 7.19-7.21 (m, 1 H), 11.40 (br s, 1 H); $^{13}C$ NMR ($CDCl_3$, 125 MHz) $\delta$ 29.9 (two overlapping q'), 32.3 (t'), 48.7 (s'), 55.1 (q'), 111.8 (d'), 112.9 (d'), 118.9 (d'), 129.0 (d'), 146.6 (s'), 159.2 (s'), 176.8 (s'); exact mass *m/z* calcd for $C_{12}H_{16}O_3S$ 240.0820, found 240.0817.

**7-Methoxy-1,1-dimethylisothiochroman-4-one (17.7).**

**17.6** **17.7**

$(CF_3CO)_2O$ (3.2 mL) was added to a stirred and cooled (0 °C) solution of acid **17.6** (389 mg, 1.62 mmol) in $CF_3CO_2H$ (8.0 mL). The cold bath was removed and the brown mixture was stirred for 2 h. The solvent was evaporated and the residue was dissolved in $Et_2O$ (100 mL) and washed with saturated aqueous $NaHCO_3$ (4 x 40 mL). The green ethereal layer was dried ($MgSO_4$) and evaporated. Flash chromatography of the residue over silica gel (2 x 20 cm), using 1:6 EtOAc-hexanes, gave **17.7** (336 mg, 93%) as a pale yellow oil: FTIR ($CDCl_3$ cast) 1673 $cm^{-1}$; $^1H$ NMR ($CDCl_3$, 500 MHz) δ 1.71 (s, 6 H), 3.58 (s, 2 H), 3.84 (s, 3 H), 6.72-6.73 (m, 1 H), 6.77-6.79 (m, 1 H), 7.98-8.01 (m, 1 H); $^{13}C$ NMR ($CDCl_3$, 125 MHz) δ 30.5 (q'), 34.1 (t'), 41.4 (q'), 55.5 (q'), 110.2 (d'), 111.5 (d'), 124.3 (s'), 131.9 (d'), 152.5 (s'), 163.2 (s'), 190.2 (s'); exact mass *m/z* calcd for $C_{12}H_{14}O_2S$ 222.0715, found 222.0715.

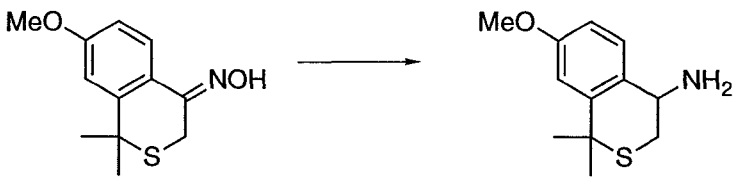
**7-Methoxy-1,1-dimethylisothiochroman-4-one Oxime (19.1).**



**17.7** **19.1**

Ketone **17.7** (131 mg, 0.590 mmol), $NH_2OH.HCl$ (246 mg, 3.54 mmol) and $AcONa.3H_2O$ (480 mg, 3.53 mmol) were dissolved in 1:1 water-EtOH (4 mL) and the mixture was warmed at 40 °C overnight. The solvent was evaporated and the residue was dissolved in $Et_2O$ (30 mL), washed with water (2 x 15 mL), dried ($MgSO_4$) and evaporated. Flash chromatography of the residue over silica gel (2 x 25 cm), using 1:6 and then 1:3 EtOAc-hexanes, gave **19.1** (140 mg, 100%) as a white solid: FTIR ($CDCl_3$ cast) 3600-3100 (br), 1603 $cm^{-1}$; $^1H$ NMR ($CDCl_3$, 400 MHz) δ 1.66 (s, 6 H), 3.82 (s, 3 H), 3.96 (s, 2 H), 6.77 (dd, *J* = 8.7, 2.6 Hz, 1 H), 6.85 (d, *J* = 2.6 Hz, 1 H), 7.75 (d, *J* = 8.7 Hz, 1 H), 8.10-8.80 (br s, 1 H); $^{13}C$ NMR ($CDCl_3$, 100 MHz) δ 22.7 (t'), 29.1 (two overlapping q'), 41.1 (s'); 54.9 (q'), 108.8 (d'), 111.0 (d'), 121.8 (s'), 127.8 (d'), 147.6 (s'), 151.7 (s'), 160.0 (s'); exact mass *m/z* calcd for $C_{12}H_{15}NO_2S$ 237.0823, found 237.0821.

**7-Methoxy-1,1-dimethylisothiochroman-4-ylamine (19.2).**



**19.1** **19.2**

$NaBH_4$ (768 mg, 19.9 mmol) was added in one portion to a stirred and cooled (0 °C) solution of oxime **19.1** (1.19 g, 4.97 mmol) in dry DME (15 mL) ($N_2$ atmosphere). After the evolution of gas had subsided, freshly distilled (at 1 atm) $TiCl_4$ (1.09 mL, 9.94 mmol) was added dropwise at 0 °C. The cold bath was left in place but was not recharged, and stirring was continued for 84 h. The resulting blue suspension was diluted with $Et_2O$ (40 mL), cooled (0 °C) and stirred vigorously with concentrated $NH_3$ in water (40 mL) for 2 h. More $Et_2O$ (200 mL) was added, and the resulting mixture was extracted with 1 N hydrochloric acid (5 x 15 mL). The acid layer was made alkaline (pH 11) with solid NaOH and extracted with $Et_2O$ (3 x 50 mL). The combined extracts were dried ($MgSO_4$) and evaporated to give **19.2** (880 mg, 79%) as a colorless liquid: FTIR ($CDCl_3$ cast) 3300 $cm^{-1}$ (doublet); $^1H$ NMR ($CDCl_3$, 300 MHz) $\delta$ 1.63 (s, 3 H), 1.65 (s, 3 H), 1.94 (br s, 2 H), 2.70 (dd, $J_{AM}$ = 13.8 Hz, $J_{AX}$ = 4.0 Hz, 1 H); 3.27 (dd, $J_{AM}$ = 13.8 Hz, $J_{MX}$ = 3.3 Hz, 1 H), 3.77 (s, 3 H), 3.99 (t, $J_{AX}$ = $J_{MX}$ = 3.6, 1 H), 6.73-6.81 (m, 2 H), 7.20 (d, $J$ =

8.8 Hz, 1 H); $^{13}C$ NMR ($CDCl_3$, 100 MHz) δ 31.3 (q'), 33.1 (t'), 33.7 (q'), 41.7 (s'), 48.9 (d'), 55.2 (q'), 111.2 (d'), 112.0 (d'), 131.5 (d'), 131.8 (s'), 144.2 (s'), 158.4 (s'); exact mass *m/z* calcd for $C_{12}H_{17}NOS$ 223.1031, found 223.1031.

**(7-Methoxy-1,1-dimethylisothiochroman-4-ylamino)-acetic Acid Ethyl Ester (20.1).**

**19.2** **20.1**

$BrCH_2CO_2Et$ (484 μL, 4.34 mmol) was added dropwise to a stirred mixture of amine **19.2** (880 mg, 3.95 mmol) and $Et_3N$ (1.10 mL, 7.89 mmol) in dry DME (20 mL). After 36 h the suspension was diluted with $Et_20$ (50 mL), washed with brine (30 mL), dried ($MgSO_4$) and evaporated. Flash chromatography of the residue over silica gel (3 x 15 cm), using 1:25:75 MeOH-EtOAc-hexanes, gave **20.1** (666 mg, 54%) as a colorless oil: FTIR ($CDCl_3$ cast) 1737 $cm^{-1}$; $^1H$ NMR ($CDCl_3$, 400 MHz) δ 1.24 (t, $J$ = 7.2, Hz, 3 H), 1.62 (s, 3 H), 1.64 (s, 3 H), 2.30 (br s, 1 H), 2.81 (dd, $J_{AM}$ = 14.0 Hz, $J_{AX}$ = 4.0 Hz, 1 H), 3.10 (dd, $J_{AM}$ = 14.0 Hz, $J_{MX}$ = 3.0 Hz, 1 H), 3.44 (ABq, $\Delta\nu_{AB}$ = 15.7 Hz, $J_{AB}$ = 17.2 Hz, 2 H), 3.76 (s, 3 H), 3.79 (t, $J_{AX}$ = $J_{MX}$ = 3.4 Hz, 1 H), 4.15 (q, $J$ = 7.1 Hz, 2 H), 6.73 (dd, $J$ = 8.6, 2.7 Hz, 1 H), 6.80 (d, $J$ = 2.6 Hz, 1 H), 7.27 (d, $J$ =

8.5 Hz, 1 H), $^{13}C$ NMR ($CDCl_3$, 100 MHz) δ 14.2 (q'), 29.0 (t'), 31.4 (q'), 34.0 (q'), 41.6 (s'), 48.2 (t'), 54.1 (d'), 55.2 (q'), 60.8 (t'), 111.5 (two overlapping d'), 128.4 (s'), 132.3 (d'), 145.0 (s'), 158.6 (s'), 172.4 (s'); exact mass *m/z* calcd for $C_{16}H_{23}NO_3S$ 309.1399, found 309.1407.

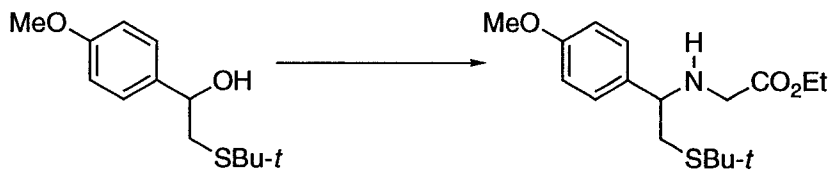
**2-*tert*-Butylsulfanyl-1-(4-methoxyphenyl)ethanol (24.1).**

**3.3** **24.1**

$NaBH_4$ (400 mg, 10.6 mmol) was added in four approximately equal portions at 15-min intervals to a stirred and cooled (0 °C) solution of ketone **3.3** (826 mg, 3.47 mmol) in dry MeOH (15 mL), and stirring was continued for 30 min at 0 °C. The solvent was evaporated and the residue was dissolved in a 1:1 mixture of water and EtOAc (80 mL) and stirred vigorously for 1 h. The organic layer was separated, and the aqueous layer was extracted with EtOAc (3 x 20 mL). The combined organic layer and extracts were dried ($MgSO_4$) and evaporated. Flash chromatography of the residue over silica gel (3 x 25 cm), using 1:3 EtOAc-hexanes, gave **24.1** (760 mg, 92%) as a colorless oil: FTIR ($CDCl_3$ cast) unexceptional; $^1H$ NMR ($CDCl_3$, 500 MHz) δ 1.33 (s, 9H), 2.72-2.77 (m containing a

broad singlet, 2 H in all), 2.88-2.92 (m, 1 H), 3.78 (s, 3 H), 4.67 (dd, $J$ = 9.4, 3.8 Hz, 1 H), 6.84-6.85 (m, 2 H), 7.25-7.27 (m, 2 H); $^{13}C$ NMR ($CDCl_3$, 125 MHz) δ 31.2 (q'), 38.7 (t'), 42.7 (s'), 55.3 (q'), 72.1 (d'), 113.8 (d'), 126.9 (d'), 134.9 (s'), 159.1 (s'); exact mass *m/z* calcd for $C_{13}H_{20}O_2S$ 240.1184, found 240.1187.

**[2-*tert*-Butylsulfanyl-1-(4-methoxyphenyl)ethyl-amino]acetic Acid Ethyl Ester (24.2).**

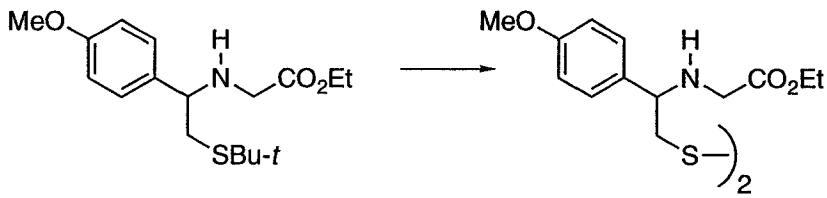


**24.1** **24.2**

$Me_3SiBr$ (63 μL, 0.48 mmol) was added dropwise to a stirred and cooled (0 °C) solution of alcohol **24.1** (114 mg, 0.475 mmol) in dry $CH_2Cl_2$ (2.0 mL). After 30 min, freshly distilled (distilled under water pump vacuum) $H_2NCH_2CO_2Et$ (98 mg, 0.95 mmol) was added in one portion. The cold bath was removed and stirring was continued for 1 h. Evaporation of the solvent, and flash chromatography of the residue over silica gel (2 x 15 cm), using 1:6 EtOAc-hexanes, gave **24.2** (105 mg, 67%) as a colorless oil: FTIR ($CDCl_3$ cast) 1738 $cm^{-1}$; $^1H$ NMR ($CDCl_3$, 400 MHz) δ 1.22 (t, $J$ = 7.1 Hz, 3 H), 1.31 (s, 9 H), 2.60 (br s, 1 H), 2.73 (dd, $J_{AB}$ = 12.3 Hz, $J_{AX}$ = 9.1 Hz, 1 H), 2.81 (dd, $J_{AB}$ = 12.3 Hz, $J_{BX}$ = 4.7 Hz, 1 H), 3.21 (ABq,

$\Delta\nu_{AB}$ = 48.5 Hz, $J_{AB}$ = 17 Hz, 2 H), 3.73 (dd, $J_{AX}$ = 9.1 Hz, $J_{BX}$ = 4.6 Hz, 1 H ), 3.78 (s, 3 H), 4.14 (q, $J$ = 7.1 Hz, 2 H), 6.86 (d, $J$ = 8.7 Hz, 2 H), 7.24 (d, $J$ = 8.6 Hz, 2 H); $^{13}C$ NMR ($CDCl_3$, 125 MHz) δ 14.3 (q'), 31.1 (q'), 37.0 (t'), 42.5 (s'), 48.8 (t'), 55.3 (q'), 60.7 (t'), 61.6 (d'), 113.9 (d'), 128.2 (d'), 134.2 (s'), 159.0 (s'), 172.1 (s'); exact mass *m/z* calcd. for $C_{17}H_{27}NNaO_3S$ (M + Na) 348.1609, found 348.1610.

**[2-[2-(Ethoxycarbonylmethylamino)-2-(4-methoxyphenyl)ethyldisulfanyl]-1-(4-methoxyphenyl)ethylamino]acetic Acid Ethyl Ester (25.1).**

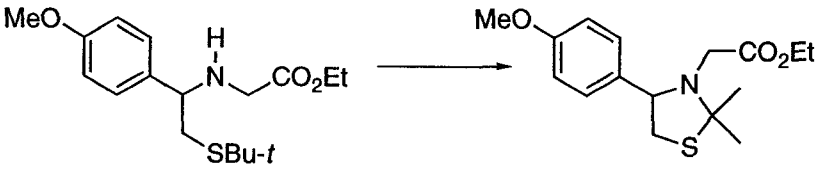


**24.2** **25.1**

$CF_3CO_2H$ (0.5 mL) was added to thioether **24.2** (54.7 mg, 0.168 mmol) contained in a flask immersed in an ice bath. The mixture was stirred and $Hg(OAc)_2$ (54.0 mg, 0.168 mmol) was added in one portion. Stirring was continued for 15 min at 0 °C. The solvent was evaporated and the residue was dissolved in MeCN (15 mL) and $H_2S$ gas was bubbled through the solution for 2 min. The resulting black suspension was filtered through a tightly packed Celite column (2 x 4 cm) and the solid was washed with several portions of MeCN.

Evaporation of the combined filtrate and washings, and flash chromatography of the residue over silica gel (2 x 18 cm), using 4:100 MeOH-$CH_2Cl_2$, gave disulfide **25.1** (31.9 mg, 70%) as a glassy liquid: FTIR ($CDCl_3$ cast) 1735 $cm^{-1}$; $^1H$ NMR ($CDCl_3$, 400 MHz) $\delta$ 1.23 (t, $J$ = 7.1 Hz, 3 H), 2.70 (dd, $J_{AB}$ = 13.5 Hz, $J_{AX}$ = 7.9 Hz, 1 H), 2.83 (dd, $J_{AB}$ = 13.4 Hz, $J_{BX}$ = 5.5 Hz, 1 H), 3.25 (ABq, $\Delta\nu_{AB}$ = 44.9 Hz, $J_{AB}$ = 17.4 Hz, 2 H), 3.70 (dd, $J_{AX}$ = 7.9 Hz, $J_{BX}$ = 5.5 Hz, 1 H), 3.79 (s, 3 H), 4.14 (q, $J$ = 7.4 Hz, 2 H), 6.85-6.87 (m, 2 H), 7.20-7.24 (m, 2 H); $^{13}C$ NMR ($CDCl_3$, 100 MHz) $\delta$ 14.1 (q'), 31.9 (t'), 48.3 (t'), 55.2 (q'), 60.8 (t'), 64.0 (d'), 114.1 (d'), 128.6 (d'), 132.5 (s'), 159.3 (s'), 171.9 (s'); exact mass $m/z$ calcd. for $C_{26}H_{36}N_2NaO_6S_2$ (M + Na) 559.1912, found 559.1912.

**[4-(4-Methoxyphenyl)-2,2-dimethylthiazolidin-3-yl]acetic Acid Ethyl Ester (25.2).**



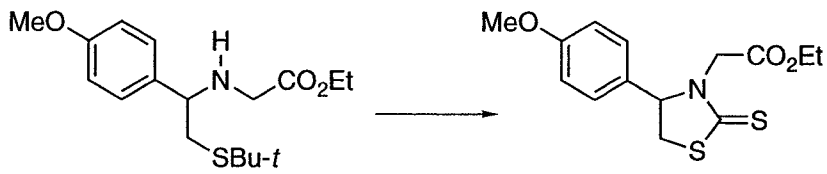
**24.2** **25.2**

$CF_3CO_2H$ (3 mL) was added to thioether **24.2** (466 mg, 1.43 mmol) contained in a flask immersed in an ice-bath. The mixture was stirred and PhOMe (0.23 mL), followed by $Hg(OAc)_2$ (458 mg, 1.43 mmol) were added. Stirring was continued for 25 min and the solvent was evaporated. The residue was

dissolved in MeCN (15 mL) and $H_2S$ gas was bubbled through the solution for 2 min. The resulting black suspension was filtered through a tightly packed Celite column (2 x 4 cm) and the solid was washed with several portions of MeCN. Evaporation of the combined filtrate and washings gave crude disulfide **25.1**, which was used directly.

A mixture of disulfide **25.1**, *p*-TsOH.$H_2O$ (10 mg) and $Bu_3P$ (1.08 mL, 8.6 mmol) in 2,2-dimethoxypropane (10 mL) was refluxed for 2 h ($N_2$ atmosphere) and then left overnight at room temperature. Evaporation of the solvent and flash chromatography of the residue over silica gel (2 x 20 cm), using 1:7, 1:6, 1:5 and then 1:3 EtOAc-hexanes, gave **25.2** (288 mg, 65%) as a colorless oil: FTIR ($CDCl_3$ cast) 1742 $cm^{-1}$; $^1H$ NMR ($CDCl_3$, 500 MHz) $\delta$ 1.14 (t, $J$ = 7.1 Hz, 3 H), 1.49 (s, 3 H), 1.58 (s, 3 H), 2.93 (dd, $J_{AB}$ = 10.3 Hz, $J_{AX}$ = 9.6 Hz, 1 H), 3.06 (dd, $J_{AB}$ = 10.4 Hz, $J_{BX}$ = 6.1 Hz, 1 H), 3.18 (s, 2 H), 3.76 (s, 3 H), 3.92-3.98 (m, 2 H), 4.49 (dd, $J_{AX}$ = 9.5 Hz, $J_{BX}$ = 5.9 Hz, 1 H), 6.80-6.82 (m, 2 H), 7.27-7.30 (m, 2 H); $^{13}C$ NMR ($CDCl_3$, 125 MHz) $\delta$ 14.2 (q'), 27.5 (q'), 30.9 (q'), 37.4 (t'), 47.0 (t'), 55.3 (q'), 60.3 (t'), 68.7 (d'), 71.6 (s'), 113.8 (d'), 129.2 (d'), 132.7 (s'), 159.2 (s'), 172.1 (s'); exact mass *m/z* calcd for $C_{16}H_{23}NNaO_3S$ (M + Na) 332.1296, found 332.1298.

**[4-(Methoxyphenyl)-2-thioxothiazolidin-3-yl]acetic Acid Ethyl Ester (27.1).**



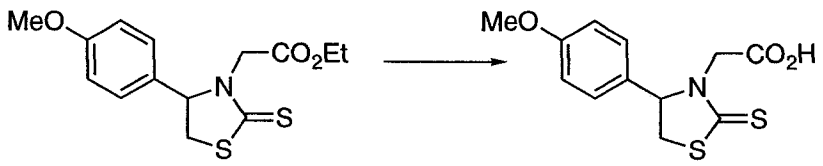
**24.2** **27.1**

$CF_3CO_2H$ (1 mL) was added to thioether **24.2** (84.3 mg, 0.268 mmol) contained in a flask immersed in an ice-bath. The mixture was stirred and PhOMe (0.04 mL), followed by $Hg(OAc)_2$ (85.4 mg, 0.268 mmol) were added. Stirring was continued for 25 min and the solvent was evaporated. The residue was dissolved in MeCN (15 mL) and $H_2S$ gas was bubbled through the solution for 2 min. The resulting black suspension was filtered through a tightly packed Celite column (2 x 4 cm) and the solid was washed with several portions of MeCN. Evaporation of the combined filtrate and washings gave crude disulfide **25.1**, which was used directly.

$Bu_3P$ (67 μL, 0.27 mmol) and 1,1'-thiocarbonyldiimidazole (106 mg, 0.53 mmol) were added to a stirred solution of the above disulfide **25.1** in dry PhH (6 mL), and the mixture was stirred overnight ($N_2$ atmosphere). Evaporation of the solvent and flash chromatography of the residue over silica gel (2 x 18 cm), using 1:3 EtOAc-hexanes and then 1:66:33 MeOH-EtOAc-hexanes, gave **27.1** (44.8 mg, 55%) as a yellow solid: $^1H$ NMR ($CDCl_3$, 300 MHz) δ 1.22 (t, $J$ = 7.2 Hz, 3 H),

3.28 (dd, $J_{AB}$ = 11.2 Hz, $J_{AX}$ = 8.8 Hz, 1 H), 3.53 (d, $J$ = 17.3 Hz, 1 H), 3.63 (dd, $J_{AB}$ = 11.2 Hz, $J_{BX}$ = 8.8 Hz, 1 H), 3.80 (s, 3 H), 4.08-4.19 (m, 2 H), 4.97 (d, $J$ = 17.3 Hz, 1 H), 5.36 (t, $J_{AX}$ = $J_{BX}$ = 8.5 Hz, 1 H), 6.90-6.93 (m, 2 H), 7.19-7.23 (m, 2 H); $^{13}C$ NMR ($CDCl_3$, 125 MHz) δ 14.2 (q'), 35.9 (t'), 48.0 (t'), 55.5 (q'), 61.6 (t'), 71.6 (d'), 114.8 (d'), 128.6 (d'), 128.9 (s'), 160.4 (s'), 167.0 (s').

**[4-(Methoxyphenyl)-2-thioxothiazolidin-3-yl]-acetic Acid (27.2).**

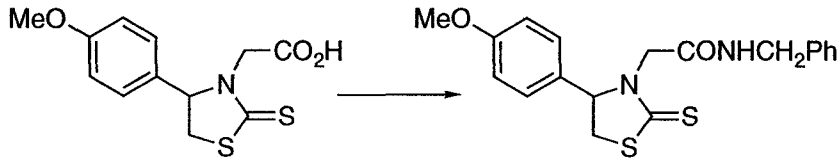


**27.1** **27.2**

A mixture of ester **27.1** (44.8 mg, 0.149 mmol) and $LiOH.H_20$ (125 mg, 2.98 mmol) in 2:1 dioxane-water (1.5 mL) was stirred vigorously at room temperature for 15 min. The mixture was poured into an ice-water mixture (30 mL) and the solution was adjusted to pH 2 with concentrated hydrochloric acid. The resulting suspension was extracted with $Et_2O$ (3 x 30 mL), and the combined extracts were dried ($MgSO_4$) and evaporated. Flash chromatography of the residue over silica gel (1.2 x 15 cm), using 1:49 AcOH-$CH_2Cl_2$, gave **27.2** (26.0 mg, 64%) as a white solid: $^1H$ NMR ($CDCl_3$, 400 MHz) δ 3.31 (dd, $J_{AB}$ = 11.2 Hz, $J_{AX}$ = 9.0 Hz, 1 H), 3.60-3.70 [overlapping

signals including d at δ 3.62 ($J$ = 17.6 Hz, 1 H), a dd at δ 3.64 ($J_{AB}$ = 11.2 Hz, $J_{BX}$ = 8.0 Hz, 1 H)], 3.82 (s, 3 H), 4.88 (d, $J$ = 17.7 Hz, 1 H), 5.33 (t, $J_{AX}$ = $J_{BX}$ = 8.6 Hz, 1 H), 6.94 (d, $J$ = 8.7 Hz, 2 H), 7.24 (d, $J$ = 9.0 Hz, 2 H).

**_N_-Benzyl-2-[4-(4-methoxyphenyl)-2-thioxothiazolidin-3-yl]acetamide (27.3).**

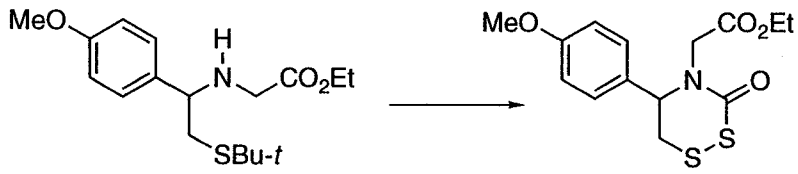


**27.2** **27.3**

EDCI (18.6 mg, 0.095 mmol) was added to a stirred and cooled (0 °C) mixture of acid **27.2** (26 mg, 0.095 mmol) and $BnNH_2$ (10.4 μL, 0.0952 mmol) in dry $CH_2Cl_2$ (2 mL). The cold bath was left in place but was not recharged, and stirring was continued overnight. The mixture was diluted with $Et_20$ (30 mL), washed with water (3 x 10 mL), dried ($MgSO_4$) and evaporated. Flash chromatography of the residue over silica gel, using 1:24:75 MeOH-EtOAc-hexanes, gave **27.3** (24.3 mg, 70%) as a white solid: FTIR ($CDCl_3$, cast) 3296 (br), 1660, 1610 $cm^{-1}$; $^1H$ NMR ($CDCl_3$, 500 MHz) δ 3.24 (dd, $J_{AB}$ = 11.3 Hz, $J_{AX}$ = 7.4 Hz, 1 H), 3.59 (d, $J$ = 15.2 Hz, 1 H), 3.66 (dd, $J_{AB}$ = 11.3 Hz, $J_{BX}$ = 8.6 Hz, 1 H), 3.78 (s, 3 H), 4.36 (d, $J$ = 5.9 Hz, 2 H), 4.79 (d, $J$ = 15.2 Hz, 1 H), 5.36 (dd, $J_{AX}$ = 7.7 Hz, $J_{BX}$ = 8.2 Hz, 1 H), 6.42 (br s, 1 H), 6.86-6.88 (m, 2 H),

7.18-7.29 (m, 7 H); $^{13}C$ NMR ($CDCl_3$, 100 MHz) δ 35.6 (t'), 43.5 (t'), 50.5 (t'), 55.4 (q'), 72.0 (d'), 114.8 (d'), 127.5 (d'), 127.6 (d'), 128.6 (d'), 128.7 (d'), 129.0 (s'), 137.6 (s'), 160.5 (s'), 166.4 (s'), 198.5 (s').

**[5-(4-Methoxyphenyl)-3-oxo-[1,2,4]dithiazinan-4-yl]acetic Acid Ethyl Ester (28.1).**

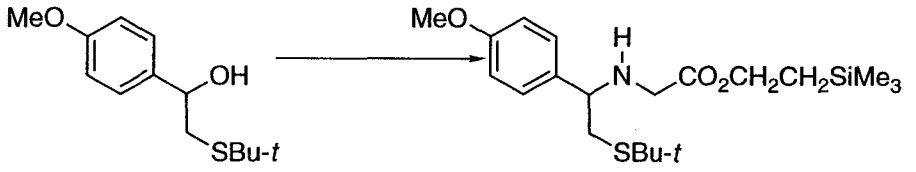


**24.2** **28.1**

Chlorocarbonylsulfenyl chloride [ClC(O)SCl] (94 μL, 1.1 mmol) was added dropwise to a stirred and cooled (-5 °C) mixture of thioether **24.2** (266 mg, 1.11 mmol) and $Et_3N$ (155 μL, 1.50 mmol) in dry $CH_2C_{12}$ (10 mL). The cold bath was left in place but was not recharged, and stirring was continued overnight. Evaporation of the solvent, and flash chromatography of the residue over silica gel (2 x 20 cm), using 1:5 and then 1:3 EtOAc-hexanes, gave **28.1** (78.2 mg, 29%) as a brown liquid: FTIR ($CDCl_3$ cast) 1743, 1624 $cm^{-1}$; $^1H$ NMR ($CDCl_3$, 500 MHz) δ 1.23 (t, $J$ = 7.2 Hz, 3 H), 3.16 (dd, $J_{AB}$ = 14.2 Hz, $J_{AX}$ = 4.4 Hz, 1 H), 3.29 (d, $J$ = 17.4 Hz, 1 H), 3.66 (dd, $J_{AB}$ = 14.2 Hz, $J_{BX}$ = 4.4 Hz, 1 H), 3.79 (s, 3 H), 4.12-4.17 (m, 2 H), 4.56 (d, $J$ = 17.3, Hz, 1 H), 5.07 (t, $J_{AX}$ = $J_{BX}$ = 4.4 Hz, 1 H), 6.88 (d, $J$ = 8.7 Hz, 2 H), 7.20 (d, $J$ =

8.7 Hz, 2 H); exact mass *m/z* calcd for $C_{14}H_{18}NO_4S_2$ (M + H) 328.0677, found 328.0677.

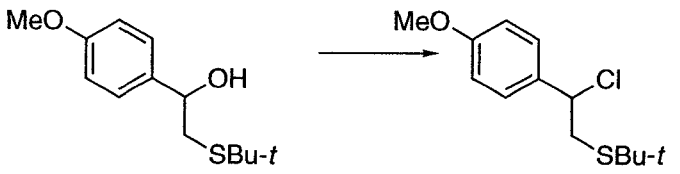
**[2-*tert*-Butylsulfanyl-1-(4-methoxyphenyl)ethyl-amino]acetic Acid 2-(Trimethylsilyl)ethyl Ester (30.1).**



**24.1** **30.1**

$Me_3SiBr$ (158 μL, 1.20 mmol) was added dropwise to a stirred solution of alcohol **24.1** (287 mg, 1.20 mmol) in dry $CH_2Cl_2$ (5 mL). After 40 min, neat amine **29.3**[32] (418 mg, 2.39 mmol) was injected in one portion, and stirring was continued for 24 h at room temperature. The mixture was poured into $Et_2O$ (50 mL), washed with saturated aqueous $NaHCO_3$ (2 x 15 mL), dried ($MgSO_4$) and evaporated. Flash chromatography of the residue over silica gel (2 x 20 cm), using 1:10, 1:7 and then 1:5 EtOAc-hexanes, gave **30.1** (235 mg, 49%) as a pale yellow oil: $^1H$ NMR ($CDCl_3$, 300 MHz) δ 0.0 (s, 9 H), 0.91-0.97 (m, 2 H), 1.30 (s, 9 H), 2.69-2.84 (m, 2 H), 3.19 (ABq, $\Delta\nu_{AB}$ = 37.9 Hz, $J_{AB}$ = 17.3 Hz, 2 H), 3.73 (dd, $J$ = 9.1, 4.9 Hz, 1 H), 3.77 (s, 3 H), 4.13-4.19 (m, 2 H), 6.83-6.86 (m, 2 H), 7.23-7.25 (m, 2 H).

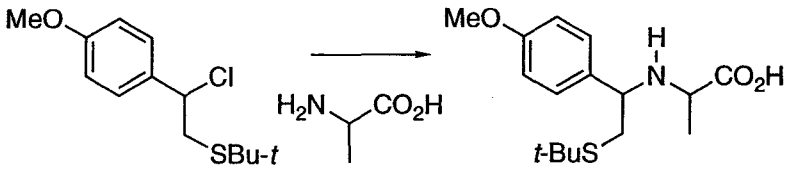
**1-(2-*tert*-Butylsulfanyl-1-chloroethyl)-4-methoxybenzene (32.1).**



**24.1** **32.1**

$SOCl_2$ (347 μL, 4.67 mmol) was added dropwise to a stirred and cooled (0 °C) solution of alcohol **24.1** (1.22 g, 4.67 mmol) in dry $CH_2Cl_2$ (6 mL). After 2 h the mixture was diluted with $Et_2O$ (80 mL), washed with saturated aqueous $NaHCO_3$ (3 x 40 mL), dried ($MgSO_4$) and evaporated to give the crude chloride **32.1** (1.16 g, 96%) as a pale yellow oil: $^1H$ NMR ($CDCl_3$, 300 MHz) δ 1.29 (s, 9 H), 3.21 (d, *J* = 8.0 Hz, 2 H), 3.78 (s, 3 H), 4.93 (t, *J* = 7.6 Hz, 1 H), 6.84-6.88 (m, 2 H), 7.28-7.31 (m, 2 H); $^{13}C$ NMR ($CDCl_3$, 100 MHz) δ 30.9 (q'), 37.4 (t'), 43.0 (s'), 55.2 (q'), 62.3 (d'), 114.0 (d'), 128.7 (d'), 132.2 (s'), 159.7 (s'). The chloride was used crude.

**2-[2-*tert*-Butylsulfanyl-1-(4-methoxyphenyl)ethylamino]propionic Acid (32.2).**



**32.1** **32.2**

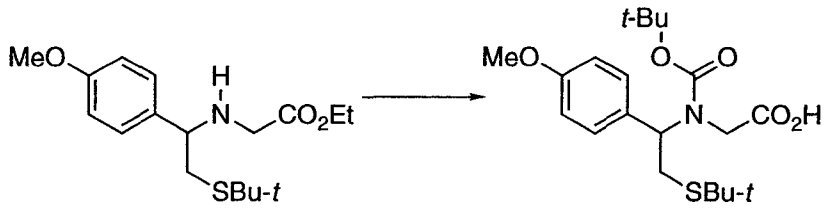
Note: This experiment was done to show that a chloride could be used and that an unprotected amino acid is suitable for reaction with the aromatic unit.

$Me_3SiCl$ (3 mmol, 381 μL) was added to a stirred suspension of (±)-alanine (267 mg, 3 mmol) in dry $CH_2Cl_2$ (6 mL) and the mixture was refluxed for 5 h. $Et_3N$ (3 mmol, 420 μL) was then added to the cooled mixture and stirring was continued for 20 min.

A solution of chloride **32.1** (729 mg, 2.82 mmol) in dry $CH_2Cl_2$ (3 mL) was added to the above mixture, which was then refluxed overnight. The mixture was cooled and poured into water (20 mL). The aqueous layer was adjusted to pH 10 with 5 N NaOH. The alkaline solution was thoroughly washed with $Et_2O$ (3 x 20 mL) and then carefully treated with concentrated hydrochloric acid to ca pH 2. The hydrochloride of **32.2** (324 mg, 31%) separated out as a brown solid consisting of an inseparable mixture of diastereoisomers: $^1H$ NMR ($CDCl_3$, 400 MHz) δ 1.22-1.30 (overlapping singlets at δ 1.26 and δ 1.27, 9 H in all), 1.50-1.64 [overlapping doublets at δ 1.53 ($J$ = 6.7 Hz) and δ 1.58 ($J$ = 6.7 Hz), 3 H in all], 3.22-3.60 (m, 3 H), 3.68-3.80 (overlapping singlets at δ 3.76 and δ 3.78, 3 H in all), 4.21-4.38 (m, 1 H), 6.84-6.94 [overlapping doublets at δ 6.88 ($J$ = 8.6 Hz) and δ 6.90 ($J$ = 8.7 Hz), 2 H in all], 7.46-7.58 [overlapping doublets at δ 7.49 ($J$ = 7.6 Hz) and δ 7.54 ($J$ = 8.2 Hz), 2 H in all]; $^{13}C$ NMR ($CDCl_3$, 100 MHz) δ (mixture of diastereoisomers) 16.6 (q'), 30.91 (q'), 30.97 (q'), 31.7 (s'), 32.0 (s'), 43.3 (t'), 45.3 (t'), 54.4 (d'),

55.1 (q'), 60.8 (d'), 62.9 (d'), 114.6 (d'), 124.8 (s'), 125.1 (s'), 130.1 (d'), 130.4 (d'), 160.4 (s'), 160.5 (s'), 172.5 (s').

**[*tert*-Butoxycarbonyl[2-*tert*-butylsulfanyl-1-(4-methoxyphenyl)ethyl]amino]acetic Acid (36.1).**



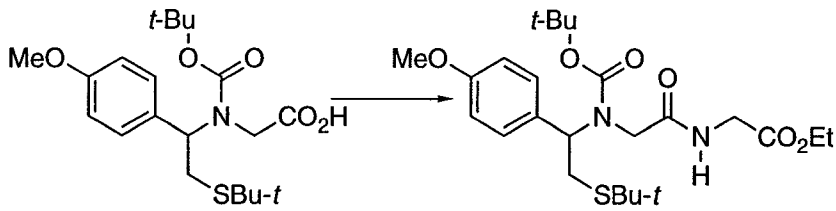
**24.2** **36.1**

$LiOH.H_2O$ (154 mg, 3.66 mmol) was added to a stirred solution of ester **24.2** (595 mg, 1.83 mmol) in 1:1 THF-water (3 mL), and the mixture was stirred vigorously for 72 h, diluted with water (15 mL) and thoroughly washed with $Et_2O$ (3 x 10 mL). The aqueous layer was concentrated to ca 3 mL, mixed with dioxane (3 mL) and cooled (0 °C). $Boc_2O$ (483 mg, 2.01 mmol) was added at 0 °C in three approximately equal portions over 1.5 h with vigorous stirring. Stirring was continued at 0 °C for 4 h, during which time a precipitate formed. The mixture was extracted with EtOAc (3 x 25 mL) and the aqueous layer was chilled (0 °C) and its pH was carefully adjusted to 7 with concentrated hydrochloric acid. The aqueous phase was extracted with EtOAc (2 x 10 mL). The combined extracts were dried ($MgSO_4$) and evaporated to give

**36.1** (497 mg, 68%) as a thick oil. Attempted chromatography over silica gel or neutral alumina (G III), using 4:96 MeOH-$CH_2Cl_2$, led to decomposition and loss of **36.1**. Acid **36.1** was used crude for the next step.

For characterization, the cyclohexylammonium salt of acid **36.1** was prepared as follows: Cyclohexylamine (114 μL, 1.20 mmol) was added to a stirred solution of acid **36.1** (199 mg, 0.50 mmol). After 30 min, hexane was added and the resulting precipitate was filtered and recrystallized from EtOAc-hexane, to give the ammonium salt (163 mg, 33%) as a white solid: mp 108-113 °C; FTIR (microscope) 3600-2100 (br), 1744, 1612 $cm^{-1}$; $^1H$ NMR ($CDCl_3$, 500 MHz) δ 1.05-1.48 (overlapping signals containing two singlets at δ 1.30 and δ 1.43, 23 H in all), 1.59 (d, *J* = 12.5 Hz, 1 H), 1.70 (d, *J* = 12.0 Hz, 2 H), 1.93 (d, *J* = 11.0 Hz, 2 H), 2.74-2.84 (m, 1 H), 3.20-3.30 (m, 3 H), 3.46-3.60 (m, 1 H), 3.75 (s, 3 H), 5.15 (br s, 0.6 H), 5.34 (br s, 0.4 H), 6.79 (d, *J* = 7.6 Hz, 2 H), 7.20 (d, *J* = 8.3 Hz, 2 H), 7.50-7.80 (br s, 3 H); $^{13}C$ NMR ($CDCl_3$, 125 MHz) δ (mixture of rotamers) 24.7 (t'), 25.0 (t'), 28.6 (q'), 30.2 (s'), 31.0 (q'), 31.7 (t'), 42.8 (t'), 48.1 (t'), 50.1 (d'), 55.2 (q'), 60.2 (d'), 80.0 (s'), 113.6 (d'), 129.3 (d'), 129.7 (d'), 131.0 (s'), 155.4 (s'), 158.7 (s'), 175.3 (s'); exact mass *m/z* calcd for $C_{26}H_{45}N_2O_5S$ (M + H) 497.3049, found 497.3053.

**[[*tert*-Butoxycarbonyl[2-*tert*-butylsulfanyl-1-(4-methoxyphenyl)ethyl]amino]acetylamino]acetic Acid Ethyl Ester (36.2).**

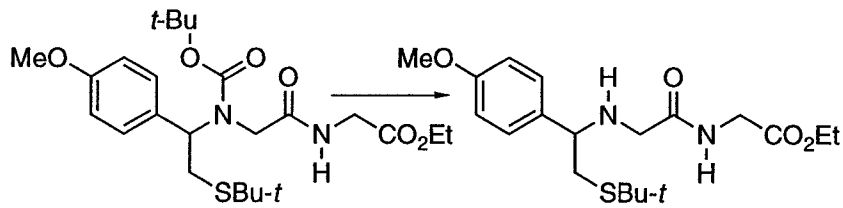


**36.1** **36.2**

$Et_3N$ (745 μL, 0.530 mmol) was added to a stirred suspension of ethyl glycine hydrochloride (103 mg, 0.750 mmol) in dry $CH_2Cl_2$ (3 mL), and the mixture was stirred for 15 min. A solution of acid **36.1** (210 mg, 0.530 mmol) in dry $CH_2Cl_2$ (2 mL) was added to the resulting solution of $H_2NCH_2CO_2Et$. The stirred mixture was cooled (0 °C) and EDCI (101 mg, 0.530 mmol) was added, followed by DMAP (5 mg). Stirring at 0 °C was continued for 1.5 h, by which time the reaction was complete (tlc control, silica, 4:96 MeOH-$CH_2Cl_2$). The mixture was poured into $Et_2O$ (40 mL), washed successively with water (2 x 15 mL) and saturated aqueous $NaHCO_3$ (2 x 15 mL), dried ($MgSO_4$) and evaporated. Flash chromatography of the residue over silica gel (2 x 15 cm), using 4:96 MeOH-$CH_2Cl_2$, gave **36.2** (163 mg, 64%) as an oil: FTIR ($CDCl_3$ cast) 3324 (br), 1750, 1689 $cm^{-1}$; $^1H$ NMR ($CDCl_3$, 300 MHz) δ 1.25 (t, $J$ = 7.1 Hz, 3 H); 1.32 (s, 9 H), 1.48 (br s, 9 H), 3.19-3.29 (m, 2 H), 3.50-3.62 (m, 2 H), 3.79 (s, 3 H), 3.80-4.00 (m, 2

H), 4.18 (q, $J$ = 7.1 Hz, 2 H), 5.34 (br s, 1 H), 6.82-6.85 (m, 2 H), 7.03 (br t, 1 H), 7.19-7.24 (m, 2 H); $^{13}C$ NMR ($CDCl_3$, 100 MHz) δ 14.1 (q'), 28.3 (q'), 30.1 (t'), 30.9 (q'), 41.1 (t'), 42.6 (t'), 47.8 (s'), 55.2 (overlapping q' and d'), 61.2 (t'), 81.4 (s'), 114.0 (d'), 128.9 (d'), 130.6 (s'), 159.3 (s'), 169.2 (s'), 170.2 (s'); exact mass *m/z* calcd for $C_{24}H_{38}N_2NaO_6S$ 505.2348 (M + Na), found 505.2347.

**[[2-*tert*-Butylsulfanyl-1-(4-methoxyphenyl)ethyl-amino]acetylamino]acetic Acid Ethyl Ester (36.3).**

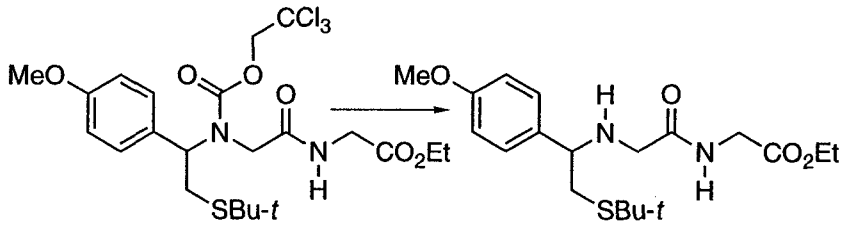


**36.2** **36.3**

$Me_3SiOSO_2CF_3$ (18.3 μL, 0.101 mmol) was added dropwise to a stirred and cooled (0 °C) solution of **36.2** (24.2 mg, 0.050 mmol) in dry $CH_2Cl_2$ (0.5 mL). The mixture was stirred for 2 h at 0 °C, diluted with $Et_2O$ (50 mL) and washed with saturated aqueous $NaHCO_3$ solution (10 mL). The organic layer was dried ($MgSO_4$) and evaporated. Flash chromatography of the residue over silica gel (2 x 9 cm), using $CH_2Cl_2$ and then 4:96 MeOH-$CH_2Cl_2$, gave **36.3** (6.9 mg, 36%) as a colorless oil: FTIR ($CDCl_3$ cast) 3307 (br), 1748, 1672, 1609 $cm^{-1}$; $^1H$ NMR ($CDCl_3$, 400 MHz) δ 1.27 (t, $J$ = 7.2, Hz, 3 H); 1.30 (s, 9 H), 1.60

(br s, 1 H), 2.71-2.81 (m, 2 H), 3.17 (ABq, $\Delta\nu_{AB}$ = 38.2 Hz, $J_{AB}$ = 17.1 Hz, 2 H), 3.68 (dd, $J$ = 9.5, 4.4 Hz, 1 H), 3.77 (s, 3 H), 3.98 (dd, $J$ = 5.6, 3.1 Hz, 2 H), 4.19 (q, $J$ = 3.1 Hz, 2 H), 6.81-6.83 (m, 2 H), 7.17-7.19 (m, 2 H), 7.70-7.72 (m, 1 H); $^{13}$C NMR ($CDCl_3$, 125 MHz) δ 14.3 (q'), 31.1 (q'), 36.5 (t'), 40.9 (t'), 42.7 (s'), 49.9 (t'), 55.3 (q'), 61.4 (t'), 62.4 (d'), 114.1 (d'), 128.0 (d'), 133.6 (s'), 159.2 (s'), 169.6 (s'), 171.6 (s'); exact mass *m/z* calcd for $C_{19}H_{31}N_2O_4S$ (M + H) 383.2004, found 383.2002.

**[2-[2-*tert*-Butylsulfanyl-1-(4-methoxyphenyl)-ethylamino]acetylamino]acetic Acid Ethyl Ester (36.3).**

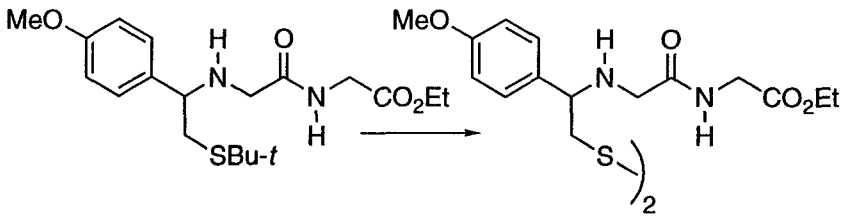


**37.3** **36.3**

Cd powder (1.20 g, 10.7 mmol) was added in one portion to a stirred solution of **37.3** (179 mg, 0.322 mmol) in 1:1 DMF-AcOH (8 mL). Stirring was continued for 45 min at room temperature, and the mixture was filtered through a Celite pad (2 x 4 cm), using EtOAc (3 x 20 mL). The combined filtrates and washings were washed with saturated aqueous $NaHCO_3$ (2 x 15 mL) and water (15 mL), dried ($MgSO_4$) and evaporated. The residue was kept under oil pump vacuum to

remove residual DMF, and crude amine **36.3** (118 mg, 97%) was obtained as a pale yellow oil, which had the same spectral data as those measured for the product made from the corresponding *N*-Boc starting material (**36.2**).

**[2-[2-[2-[[(Ethoxycarbonylmethylcarbamoyl)-methyl]amino]-2-(4-methoxyphenyl)ethyldisulfanyl]-1-(4-methoxyphenyl)ethylamino]acetylamino]acetic Acid Ethyl Ester (36.4).**



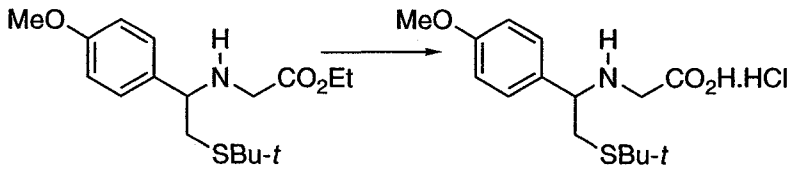
**36.3** **36.4**

In this experiment the initial product was not protected from air, and so the disulfide was obtained.

$CF_3CO_2H$ (2 mL) was added to thioether **36.3** (118 mg, 0.311 mmol) contained in a flask immersed in an ice-bath. The mixture was stirred and PhOMe (50 μL), followed by $Hg(OAc)_2$ (99.3 mg, 0.311 mmol) were added. Stirring was continued for 25 min and the solvent was evaporated. The residue was dissolved in MeCN (15 mL) and $H_2S$ gas was bubbled through the solution for 2 min. The resulting black suspension was filtered through a tightly packed Celite column (2 x 4 cm) and the solid was washed with several

portions of MeCN. Evaporation of the combined filtrate and washings, and flash chromatography of the residue over silica gel (2 x 18 cm), using 4:100 MeOH-$CH_2Cl_2$, gave disulfide **36.4** (92.4 mg, 92%) as a colorless oil: FTIR ($CDCl_3$ cast) 1745, 1668 $cm^{-1}$; $^1H$ NMR ($CDCl_3$, 500 MHz) $\delta$ 1.26 (t, $J$ = 7.1 Hz, 6 H), 2.74 (dd, $J_{AB}$ = 13.7 Hz, $J_{AX}$ = 8.0 Hz, 2 H), 3.23 (ABq, $\Delta\nu_{AB}$ = 15.4 Hz, $J_{AB}$ = 17.0 Hz, 4 H), 2.85 (dd, $J_{AB}$ = 13.7 Hz, $J_{BX}$ = 5.3 Hz, 2 H), 3.71 (dd, $J_{AX}$ = 7.8 Hz, $J_{BX}$ = 5.4 Hz, 2 H), 3.76 (s, 6 H), 3.96 (dd, $J_{AB}$ = 18.3 Hz, $J_{AX}$ = 5.4 Hz, 2 H), 4.02 (dd, $J_{AB}$ = 18.3 Hz, $J_{BX}$ = 5.6 Hz, 2 H), 4.19 (q, $J$ = 7.1 Hz, 4 H), 6.82-6.85 (m, 4 H), 7.14-7.17 (m, 4 H), 7.65 (br t, $J$ = 4.5 Hz, 2 H); $^{13}C$ NMR ($CDCl_3$, 125 MHz) $\delta$ 14.2 (q'), 31.6 (t'), 41.0 (t'), 49.5 (t'), 55.3 (q'), 61.5 (t'), 64.3 (d'), 114.2 (d'), 128.3 (d'), 131.8 (s'), 159.4 (s'), 169.7 (s'), 170.9 (s'); exact mass $m/z$ calcd for $C_{30}H_{43}N_4O_8S$ (M + H) 651.2522, found 651.2524.

**[2-*tert*-Butylsulfanyl-1-(4-methoxyphenyl)ethyl-amino]acetic Acid Hydrochloride (37.1).**

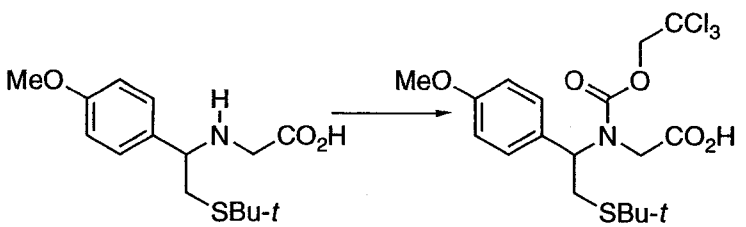


**24.2** **37.1**

NaOH (1.29 g, 32.4 mmol) was added to a stirred solution of ester **24.2** (1.034 g, 3.24 mmol) in 1:1 THF-water (28 mL).

After 4 h the mixture was diluted with water (25 mL) and washed with $Et_2O$ (3 x 25 mL). The aqueous layer was cooled (0 °C), acidified to pH 1-2 with concentrated hydrochloric acid and then evaporated to dryness. The residue was mixed with MeOH (100 mL) and the mixture was warmed slightly. The mixture was filtered, and the filtrate was evaporated to give amino acid hydrochloride **37.1** (1.08 g, 100%) as a pale yellow foam: FTIR ($CDCl_3$ cast) 3400-2400 (br), 1689 $cm^{-1}$; $^1H$ NMR ($CD_3OD$, 500 MHz) $\delta$ 1.30 (s, 9 H), 3.19 (dd, $J_{AB}$ = 12.9 Hz, $J_{AX}$ = 9.5 Hz, 1 H), 3.27-3.30 (m, 1 H), 3.62 (ABq, $\Delta\nu_{AB}$ = 28.8 Hz, $J_{AB}$ = 17.0 Hz, 2 H), 3.81 (s, 3 H), 4.40 (dd, $J$ = 9.6, 6.0 Hz, 1 H), 7.00 (dd, $J$ = 6.8, 1.9 Hz, 2 H), 7.38 (dd, $J$ = 6.8, 2.1 Hz, 2 H); $^{13}C$ NMR ($CDCl_3$, 125 MHz) $\delta$ 31.2 (q'), 31.9 (t'), 44.2 (s'), 46.4 (t'), 56.0 (q'), 63.4 (d'), 115.7 (d'), 125.7 (s'), 131.1 (d'), 162.1 (s'), 168.7 (s'); exact mass *m/z* calcd for $C_{15}H_{23}NNaO_3S$ (M + Na) 320.1296, found 320.1297.

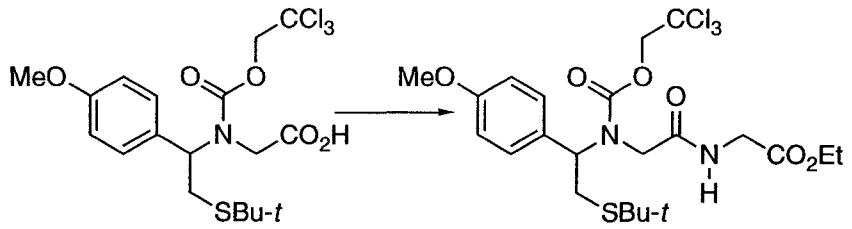
**[[2-*tert*-Butylsulfanyl-1-(4-methoxyphenyl)ethyl]-(2,2,2-trichloroethoxycarbonyl)amino]acetic Acid (37.2).**



**37.1** **37.2**

Neat $Cl_3CCH_2OCOCl$ (400 μL, 2.90 mmol) and 1 N NaOH (380 μL) were added alternately in ten equal portions by syringe over 1.5 h to a stirred and cooled (0 °C) suspension of **37.1** (430 mg, 1.45 mmol) in 1 N NaOH (1.70 mL). When addition was complete the cold bath was removed and stirring was continued for 11 h, by which time all **37.1** had reacted. The mixture was cooled (0 °C), acidified to pH 2 with concentrated hydrochloric acid, and extracted with EtOAc (3 x 20 mL). The combined organic extracts were dried ($MgSO_4$) and evaporated. Flash chromatography of the residue over silica gel (2 x 20 cm), using 2:100 and then 4:96 MeOH-$CH_2Cl_2$, gave **37.2** (510 mg, 74%) as a thick oil: FTIR ($CDCl_3$ cast) 1716, 1611 $cm^{-1}$; $^1H$ NMR ($CDCl_3$, 400 MHz) (mixture of rotamers) δ 1.31 (s, 4 H), 1.33 (s, 5 H), 3.01-3.15 (m, 2 H), 3.67-3.83 (m containing a singlet at δ 3.77, 5 H in all), 4.73-4.81 (m, 1 H), 4.87 (ABq, $\Delta\nu_{AB}$ = 92.0 Hz, $J_{AB}$ = 11.9 Hz, 2 H), 5.43-5.50 (m, 1 H), 6.84-6.87 (m, 2 H), 7.21-7.24 (m, 2 H); $^{13}C$ NMR ($CDCl_3$, 100 MHz) (mixture of rotamers) δ 29.1 (s'), 29.6 (s'), 30.9 (q'), 43.0 (t'),43.2 (t'), 44.9 (t'), 45.2 (t'), 55.3 (q'), 59.6 (d'), 60.0 (d'), 75.4 (t'), 75.6 (t'), 95.1 (s'), 95.2 (s'), 114.2 (d'), 114.3 (d'), 128.4 (s'), 128.5 (d'), 129.4 (d'), 129.6 (d'), 129.7 (d'), 129.8 (d'), 154.2 (s'), 154.4 (s'), 159.6 (s'), 173.5 (s'), 174.1 (s'); exact mass *m/z* calcd. for $C_{18}H_{24}Cl_3NNaO_5S$ (M + Na) 494.0338, found 494.0338.

**[2-[[2-*tert*-Butylsulfanyl-1-(4-methoxyphenyl)-ethyl](2,2,2-trichloroethoxycarbonyl)amino]acetyl-amino]acetic Acid Ethyl Ester (37.3).**



**37.2** **37.3**

Ethyl glycinate hydrochloride (5.2 g, 38.6 mmol) was mixed with solid $K_2CO_3$ (10 g, 72.4 mmol) and a few drops of saturated aqueous NaCl and the mixture was ground with a pestle and mortar to form a thick paste. This was extracted with $Et_2O$, and the combined extracts were dried ($MgSO_4$) and evaporated. The resulting crude $H_2NCH_2CO_2Et$ was distilled (60 °C, water pump) to afford pure ($^1H$ NMR) $H_2NCH_2CO_2Et$ (2.3 g, 62%).

EDCI (207 mg, 1.08 mmol) was added to a stirred and cooled (0 °C) solution of acid **37.2** (510 mg, 1.08 mmol) and $H_2NCH_2CO_2Et$ (110 µL, 1.08 mmol) in dry $CH_2Cl_2$ (12 mL). After 15 min the cold bath was removed and stirring was continued for 2 h. The mixture was diluted with $Et_2O$ (100 mL), washed with water (2 x 25 mL), dried ($MgSO_4$) and evaporated. Flash chromatography of the residue over silica gel (2 x 20 cm), using 1:99, 2:98 and then 4:96 MeOH-$CH_2Cl_2$, gave **37.3** (374 mg, 62%) as a gum: FTIR ($CDCl_3$ cast) 3323 (br), 1747, 1716,

1611 $cm^{-1}$; $^1H$ NMR ($CDCl_3$, 300 MHz) (mixture of rotamers) δ 1.24 (t, *J* = 7.1 Hz, 3 H), 1.32 (br s, 9 H), 3.04-3.29 (br m, 2 H), 3.64-3.76 (br, 2 H), 3.76 (s, 3 H), 3.81-3.96 (m, 2 H), 4.17 (q, *J* = 7.1 Hz, 2 H), 4.74-4.83 (br m, 1.6 H), 5.00-5.10 (br m, 0.4 H), 5.32-5.56 (br m, 1 H), 6.70-6.80 (br s, 1 H), 6.80-6.94 (m, 2 H), 7.21-7.30 (m, 2 H); $^{13}C$ NMR ($CDCl_3$, 100 MHz) (mixture of rotamers) δ 14.1 (q'), 29.7 (t'), 30.9 (q'), 41.2 (t'), 42.9 (t'), 47.7 (t'), 55.2 (q'), 59.7 (d'), 60.4 (d'), 61.4 (t'), 75.5 (s'), 95.2 (s'), 114.2 (d'), 129.1 (d'), 129.6 (s'), 154.6 (s'), 159.6 (s'), 168.8 (s'), 169.2 (s'); exact mass *m/z* calcd for $C_{22}H_{31}Cl_3N_2NaO_6S$ (M + Na) 579.0866, found 579.0868.

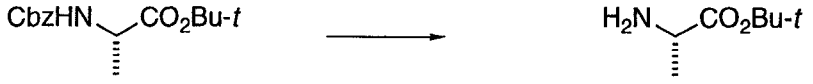
**(*S*)-2-(Benzyloxycarbonylamino)propionic Acid *tert*-Butyl Ester (38.3).**

**38.2** **38.3**

A solution of *t*-butyl trichloroacetimidate [$Cl_3CC(=NH)$-OBu-*t*] (13.8 g, 63.2 mmol) in dry cyclohexane (distilled from $CaH_2$) (60.9 mL) was added over 10 min to a stirred and cooled (0 °C) solution of **38.2** (7.05 g, 31.6 mmol) in dry $CH_2Cl_2$ (30.4 mL), followed by $BF_3.OEt_2$ (610 μL, 4.81 mmol), which was also added over ca 10 min. Stirring was continued for 14 h and the mixture was neutralized with solid $NaHCO_3$ (5 g).

Evaporation of the solvent and flash chromatography of the residue over silica gel (2 x 20 cm), using 1:9 acetone-hexanes, gave **38.3** (7.72 g, 87%) as a colorless oil: $[\alpha]^{20}_{D}$ -28.4° (*c* 1, EtOH); FTIR ($CHCl_3$ cast) 3339, 1723 $cm^{-1}$; $^1H$ NMR ($CDCl_3$, 400 MHz) δ 1.36 (d, *J* = 7.1 Hz, 3 H), 1.44 (s, 9 H), 4.20-4.27 (m, 1 H), 5.05-5.12 (m, 2 H), 5.30-5.41 (br m, 1 H), 7.28-7.34 (m, 5 H); $^{13}C$ NMR ($CDCl_3$, 100 MHz) δ 18.8 (q'), 27.9 (q'), 50.1 (d'), 66.7 (t'), 81.8 (s'), 128.0 (d'), 128.3 (d'), 128.4 (d'), 136.4 (s'), 156.5 (s'), 172.1 (s'); exact mass *m/z* calcd for $C_{15}H_{21}NNaO_4$ (M + Na) 302.1363, found 302.1362.

**(2*S*)-2-Aminopropionic Acid *tert*-Butyl Ester (38.4).**

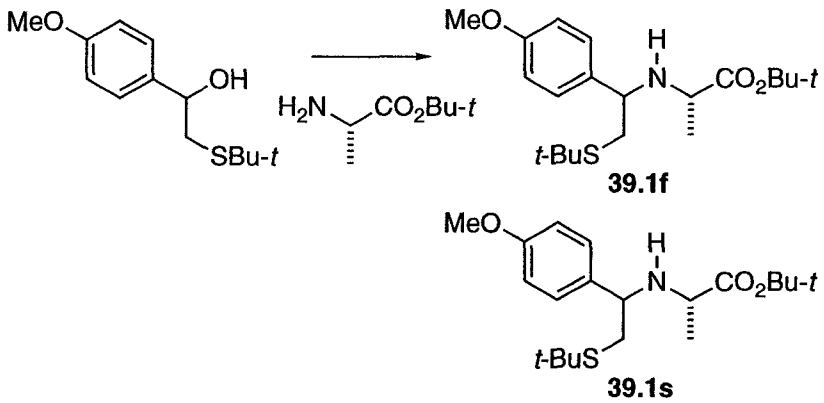


**38.3** **38.4**

10% Pd-C (778 mg, 25% weight of **38.3**) was added slowly, under a continuous stream of $N_2$, to a solution of carbamate **38.3** (3.11 g, 7.84 mmol) in dry MeOH (60 mL). The flask was purged with $H_2$ gas and the mixture was stirred under a $H_2$ atmosphere, using a balloon. After 6 h, the mixture was filtered through a Celite pad (3 x 5 cm), using MeOH (25 mL). The combined filtrate and washings were carefully evaporated (the product is volatile) to yield amine **38.4** (1.84 g, 89%)

as a pale yellow oil: $[\alpha]^{20}_{D}$ +2.3° (*c* 1, $CHCl_3$); FTIR ($CHCl_3$ cast) 1731 $cm^{-1}$; $^1H$ NMR ($CDCl_3$, 500 MHz) δ 1.29 (d, *J* = 7.0 Hz, 3 H), 1.43 (s, 9 H), 2.33 (br s, 2 H), 3.43 (q, *J* = 7.0 Hz, 1 H); $^{13}C$ NMR ($CDCl_3$, 125 MHz) δ 20.4 (q'), 28.0 (q'), 50.6 (d'), 81.0 (s'), 175.1 (s'); exact mass *m/z* calcd for $C_7H_{16}NO_2$ (M + H) 146.1181, found 146.1183. Examination of the Mosher amide showed ($^{19}F$ NMR) showed no epimerization.

**(2*S*)-2-[2-*tert*-Butylsulfanyl-1-(4-methoxyphenyl)-ethylamino]propionic Acid *tert*-Butyl Ester (less polar isomer) (39.1f) and (2*S*)-2-[2-*tert*-Butylsulfanyl-1-(4-methoxyphenyl)ethylamino]propionic Acid *tert*-Butyl Ester (more polar isomer) (39.1s).**



**24.1** **39.1f & 39.1s**

$Me_3SiBr$ (295 μL, 2.23 mmol) was added dropwise to a stirred and cooled (0 °C) solution of alcohol **24.1** (537 mg, 2.23 mmol) in dry $CH_2Cl_2$ (11 mL). After 20 min freshly prepared amine **38.4** (see conversion of **38.3** to **38.4**) (653

mg, 4.47 mmol) was added in one portion. The cold bath was left in place but was not recharged, and stirring was continued for 2 days. Evaporation of the solvent and flash chromatography of the residue over silica gel (3 x 20 cm), using 1:7 EtOAc-hexanes, gave a fast-eluting diastereoisomer **39.1f** (262 mg, 31.8%) as a pale yellow oil and a slow-eluting diastereoisomer **39.1s** (251 mg, 30.5%) as a colorless oil. Isomer **39.1f** had: $[\alpha]^{20}_{D}$ -89.8° (*c* 1.0, $CHCl_3$); FTIR ($CHCl_3$ cast) 1728 $cm^{-1}$; $^1H$ NMR ($CDCl_3$, 400 MHz) δ 1.17 (d, *J* = 7.0 Hz, 3 H), 1.30 (s, 9 H), 1.45 (s, 9 H), 2.46-2.54 (br s, 1 H), 2.66 (dd, $J_{AB}$ = 11.7 Hz, $J_{AX}$ = 9.5 Hz, 1 H), 2.76 (dd, $J_{AB}$ = 12.1 Hz, $J_{BX}$ = 4.2 Hz, 1 H), 2.93 (q, *J* = 7.1 Hz, 1 H), 3.67 (dd, $J_{AX}$ = 9.5 Hz, $J_{BX}$ = 4.2 Hz, 1 H), 3.78 (s, 3 H), 6.83-6.86 (m, 2 H), 7.22-7.25 (m, 2 H); $^{13}C$ NMR ($CDCl_3$, 125 MHz) δ 19.7 (q'), 28.2 (q'), 31.0 (q'), 37.4 (t'), 42.4 (s'), 54.7 (d'), 55.3 (q'), 60.2 (d'), 80.6 (s'), 113.9 (d'), 128.3 (d'), 134.9 (s'), 158.9 (s'), 174.9 (s'); exact mass *m/z* calcd for $C_{20}H_{33}NNaO_3S$ (M + Na) 390.2079, found 390.2074.

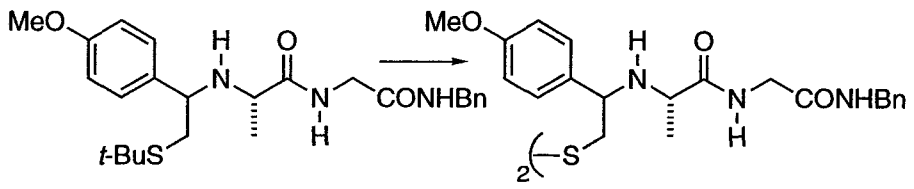
***N*-(Benzylcarbamoylmethyl)-2-[2-[2-[1-[(benzylcarbamoylmethyl)carbamoyl]ethylamino]-2-(4-methoxyphenyl)ethyldisulfanyl]-1-(4-methoxyphenyl)ethylamino]propionamide (41.5s).**



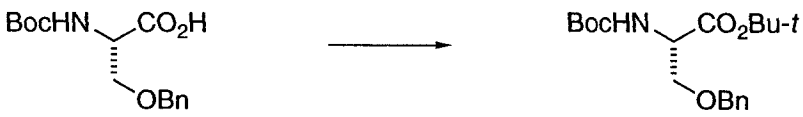
**41.4s** **41.5s**

In this experiment the initial thiol product was not protected from air, and the compound isolated was the

corresponding disulfide **41.5s**.

$CF_3CO_2H$ (1.0 mL) was added to thioether **41.4s** (156 mg, 0.342 mmol) contained in a flask immersed in an ice-bath. The mixture was stirred and PhOMe (62 μL), followed by $Hg(OAc)_2$ (109 mg, 0.342 mmol) were added. Stirring was continued for 25 min and the solvent was evaporated. The residue was dissolved in MeCN (15 mL) and $H_2S$ gas was bubbled through the solution for 2 min. The resulting black suspension was filtered through a tightly packed Celite column (2 x 4 cm) and the solid was washed with several portions of MeCN. Evaporation of the combined filtrate and washings, and flash chromatography of the residue over silica gel (2 x 18 cm), using 4:100 MeOH-$CH_2Cl_2$, gave **41.5s** (124 mg, 73%) as a pale brown oil: $[\alpha]^{20}_D$ -7.0 (c 0.74, MeOH); FTIR (MeOH, cast) 3291, 1651 $cm^{-1}$; $^1H$ NMR ($CD_3OD$, 500 MHz) δ 1.31 (d, $J$ = 7.0 Hz, 6 H), 2.72-2.83 (m, 4 H), 3.13-3.20 (m, 2 H), 3.71-3.83 (m containing a singlet at δ 3.73, 12 H in all), 4.37 (s, 4 H), 6.81-6.85 (m, 4 H), 7.18-7.29 (m, 14 H); $^{13}C$ NMR ($CD_3OD$, 125 MHz) (mixture of rotamers) δ 18.1 (q'), 18.4 (d'), 31.6 (t'), 43.4 (t'), 44.2 (t'), 46.4 (t'), 55.8 (q'), 60.7 (d'), 64.7 (d'), 115.0 (d'), 128.2 (d'), 128.4 (d'), 128.5 (d'), 129.5 (d'), 130.0 (d'), 130.0 (d'), 130.1 (s'), 139.7 (s'), 160.8 (s'), 160.9 (s'), 171.0 (s'); exact mass $m/z$ calcd for $C_{42}H_{53}N_6O_6S_2$ (M + H) 801.3462, found 801.3467.

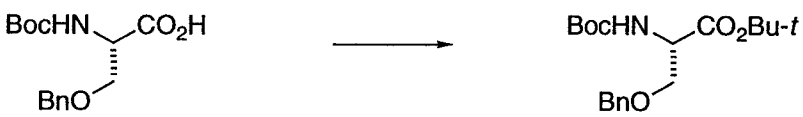
**(2*S*)-3-Benzyloxy-2-*tert*-butoxycarbonylamino-propionic Acid *tert*-Butyl ester (42.2).**



**42.1** **42.2**

DMAP (504 mg, 4.13 mmol) was added in one portion to a stirred solution of **42.1** (4.06 g, 13.8 mmol) and $Boc_2O$ (4.34 g, 19.3 mmol) in dry *t*-BuOH (90 mL). Rapid evolution of gas occurred. After 3 h, the solvent was evaporated and flash chromatography of the residue over silica gel (4 x 25 cm), using 1:9 acetone-hexanes, gave **42.2** (1.98 g, 41%) as a colorless oil: $[\alpha]^{20}_D$ +6.5° (*c* 1, $CHCl_3$). We subsequently found that the material had been partially epimerized, and a better synthetic route is described below.

**(2*S*)-3-Benzyloxy-2-(*tert*-butoxycarbonylamino)-propionic Acid *tert*-Butyl Ester (42.2).**

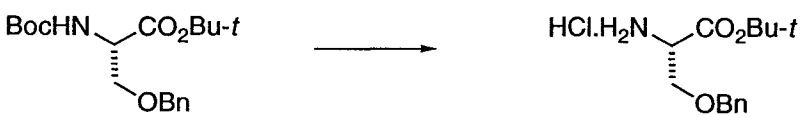


**42.1** **42.2**

The following is the best procedure for making the t-butyl ester, as epimerization, if any, appears to be very slight.

A solution of *t*-butyl trichloroacetimidate [$Cl_3CC(=NH)$-OBu-*t*] (13.9 g, 63.6 mmol) in dry cyclohexane (60.9 mL) was added over 10 min to a stirred and cooled (0 °C) solution of **42.1** (8.98 g, 30.4 mmol) in dry $CH_2Cl_2$ (30.4 mL), followed by $BF_3.OEt_2$ (610 μL, 4.81 mmol), which was also added over ca 10 min. Stirring was continued for 14 h and the mixture was neutralized with solid $NaHCO_3$ (5 g). Evaporation of the solvent and flash chromatography of the residue over silica gel (2 x 20 cm), using 1:9 acetone-hexanes, gave **42.2** (6.76 g, 63%) as a pale yellow oil: $[\alpha]^{20}_D$ +8.0° (*c* 1, $CHCl_3$); FTIR ($CH_2Cl_2$ cast) 1716 $cm^{-1}$; $^1H$ NMR ($CDCl_3$, 500 MHz) δ 1.432 (s, 9 H), 1.435 (s, 9 H), 3.64 (dd, $J_{AB}$ = 9.3 Hz, $J_{AX}$ = 3.1 Hz, 1 H), 3.83 (dd, $J_{AB}$ = 9.3 Hz, $J_{BX}$ = 3.1 Hz, 1 H), 4.28-4.32 (m, 1 H), 4.50 (ABq, $\Delta\nu_{AB}$ = 30.8 Hz, $J_{AB}$ = 12.1 Hz, 2 H), 5.35 (d, $J$ = 8.4 Hz, 1 H), 7.24-7.34 (m, 5 H); $^{13}C$ NMR ($CDCl_3$, 125 MHz) δ 28.0 (q'), 28.4 (q'), 54.4 (d'), 70.5 (t'), 73.3 (t'), 79.6 (s'), 81.9 (s'), 127.4 (d'), 127.6 (d'), 128.3 (d'), 137.6 (s'), 155.4 (s'), 169.5 (s'); exact mass *m/z* calcd for $C_{19}H_{29}NNaO_5$ (M + Na) 374.1943, found 374.1945.

**(2*S*)-2-Amino-3-benzyloxypropionic Acid *tert*-Butyl Ester Hydrochloride (42.3).**



**42.2** **42.3**

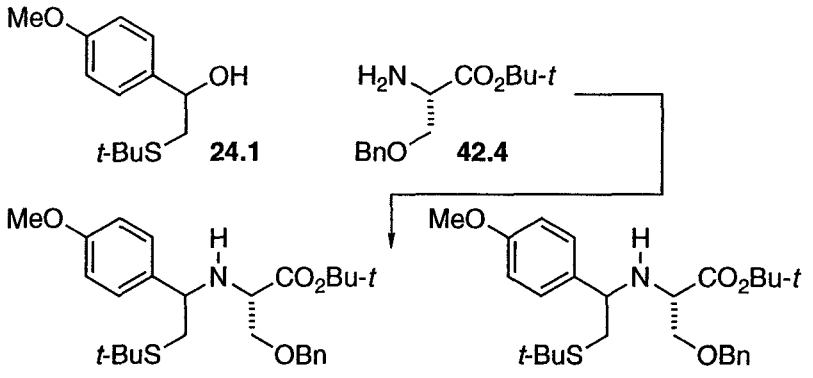
Dry HCl gas was passed into cold (0 °C) EtOAc (50 mL) for 20 min and the solution was allowed to warm slowly to room temperature. A portion of this solution (7.5 N[46] 4.49 mL, 33.7 mmol) was added to a stirred solution of **42.2** (made by use of *t*-butyl trichloroacetimidate, 1.99 g, 6.73 mmol) in EtOAc (29.2 mL) contained in a round-bottom flask fitted with a rubber septum, and stirring was continued for 18 h. The resulting precipitate was collected, and recrystallization from MeOH-EtOAc, gave **42.3** (1.09 g, 67%) as a white, fluffy solid: $[\alpha]^{20}_{D}$ -4.3° (*c* 1, MeOH); mp 181-183 °C; FTIR (MeOH cast) 3700-3400 (br), 1736 $cm^{-1}$; $^{1}H$ NMR ($CD_3OD$, 500 MHz) δ 1.48 (s, 9 H), 3.78 (dd, $J_{AB}$ = 10.4 Hz, $J_{AX}$ = 3.1 Hz, 1 H), 3.90 (dd, $J_{AB}$ = 10.4 Hz, $J_{BX}$ = 4.2 Hz, 1 H), 4.13 (dd, $J_{AX}$ = 3.1 Hz, $J_{BX}$ = 4.2 Hz, 1 H), 4.57 (ABq, $\Delta\nu_{AB}$ = 58.3 Hz, $J_{AB}$ = 12.0 Hz, 2 H), 7.26-7.34 (m, 5 H); $^{13}C$ NMR ($CD_3OD$, 100 MHz) δ 28.1 (q'), 54.9 (d'), 68.2 (t'), 74.6 (t'), 85.3 (s'), 129.2 (d'), 129.24 (d'), 129.55 (d'), 138.4 (s'), 167.6 (s'); exact mass *m/z* calcd for $C_{14}H_{22}NO_3$ (M + H) 252.1600, found 252.1604.

**(2*S*)-3-Benzyloxy-2-[(2*R*)-(3,3,3-trifluoro-2-methoxy-2-phenylpropionylamino)]propionic Acid *tert*-Butyl Ester (Mosher Amide).**

**42.3** -

$Et_3N$ (23.1 μL, 0.165 mmol) was added to a stirred and cooled (0 °C) mixture of (-)-α-methoxy-α-trifluoromethyl-phenyl acetic acid (77.2 mg, 0.330 mmol) and amine hydrochloride **42.3** (47.4 mg, 0.165 mmol) in dry $CH_2Cl_2$ (1.5 mL), followed by EDCI (64.5 mg, 0.330 mmol). Stirring was continued at 0 °C for 3 h by which time all **42.3** had reacted (tlc control, silica, 1:4 EtOAc-hexanes). Evaporation of the mixture and flash chromatography of the residue over silica gel (1 x 15 cm), using 1:4 EtOAc-hexanes, gave the Mosher amide (72.6 mg, 94.3%) as a colorless oil: $[\alpha]^{20}_D$ -12.1° (*c* 1.0, MeOH); FTIR (MeOH cast) 1678 $cm^{-1}$; $^1H$ NMR ($CDCl_3$, 500 MHz) δ 1.47 (s, 9 H), 3.49 (s, 3 H), 3.62 (dd, *J* = 9.6, 3.1 Hz, 1 H), 3.82 (dd, *J* = 9.6, 3.1 Hz, 1 H), 4.40 (ABq, $\Delta\nu_{AB}$ = 16.1 Hz, $J_{AB}$ = 12.1 Hz, 2 H), 4.63-4.66 (m, 1 H), 7.13-7.15 (m, 2 H), 7.21-7.35 (m, 6 H), 7.44 (br d, *J* = 8.0 Hz, 1 H), 7.50-7.51 (m, 2 H); $^{13}C$ NMR ($CDCl_3$, 125 MHz) δ 28.0 (q'), 53.1 (q'), 55.2 (d'), 69.6 (t'), 73.3 (t'), 82.7 (s'), 83.9 (q, *J* = 26.3 Hz), 122.5 (s'), 124.8 (s'), 127.4 (d'), 127.6 (d'), 127.7 (d'), 128.3 (d'), 129.3 (d'), 132.8 (s'), 137.4 (s'), 165.9 (s'), 168.4 (s'); $^{19}F$ NMR ($CDCl_3$, 468 MHz) δ -69.52 (s, integral 1.24), -69.08 (s, integral 88.45); exact mass *m/z* calcd for $C_{24}H_{28}F_3NO_5Na$ (M + Na) 490.1812, found 490.1812. The $^{19}F$ NMR spectrum indicated an ee of 97.2%.

**(2*S*)-3-Benzyloxy-2-[2-*tert*-butylsulfanyl-1-(4-methoxyphenyl)ethylamino]propionic Acid *tert*-Butyl Ester (less polar isomer) (43.1f) and (2*S*)-3-Benzyloxy-2-[2-*tert*-butylsulfanyl-1-(4-methoxyphenyl)-ethylamino]propionic Acid *tert*-Butyl Ester (more polar isomer) (43.1s).**

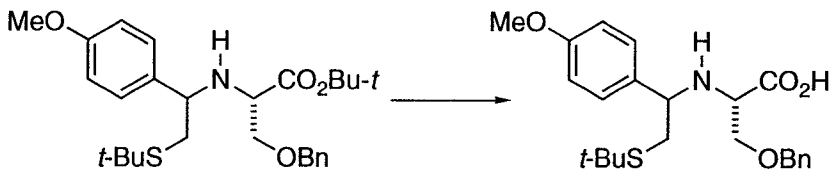


$Me_3SiBr$ (390 μL, 2.93 mmol) was added dropwise to a stirred and cooled (0 °C) solution of alcohol **24.1** (704 mg, 2.93 mmol) in dry $CH_2Cl_2$. After 40 min, a solution of **42.4** (1.47 g, 5.87 mmol) in dry $CH_2Cl_2$ (3 mL) was injected in one portion. Stirring was continued for 3 h without recharging the cold bath. Evaporation of the solvent and flash chromatography of the residue over silica gel (3.5 x 25 cm), using 4:12:100 *t*-BuOMe-$Et_2O$-petroleum ether (35-60 °C), gave the faster-eluting diastereoisomer **43.1f** (422 mg, 30%) as a colorless oil. The slower-eluting fraction was resubjected to flash chromatography over silica gel (3.5 x 25 cm), using 1:9 EtOAc-hexanes, to obtain **43.1s** (539 mg, 38%) as a

colorless oil. Isomer **43.1f** had: $[\alpha]^{20}_{D}$ -60.0° (*c* 1.0, $CH_2Cl_2$); FTIR ($CH_2Cl_2$ cast) 3311, 1730 $cm^{-1}$; $^1H$ NMR ($CDCl_3$, 500 MHz) δ 1.29 (s, 9 H), 1.44 (s, 9 H), 2.66 (dd, $J_{AB}$ = 12.1 Hz, $J_{AX}$ = 9.3 Hz, 1 H), 2.75 (dd, $J_{AB}$ = 12.2 Hz, $J_{BX}$ = 4.7 Hz, 1 H), 2.72-2.80 (br s, 1 H), 3.08 (t, *J* = 5.1 Hz, 1 H), 3.49 (dd, $J_{AB}$ = 9.0 Hz, $J_{AX}$ = 5.4 Hz, 1 H), 3.57 (dd, $J_{AB}$ = 9.1 Hz, $J_{BX}$ = 4.7 Hz, 1 H), 3.74 (dd, $J_{AX}$ = 9.2 Hz, $J_{BX}$ = 4.8 Hz, 1 H), 3.76 (s, 3 H), 4.44 (ABq, $\Delta\nu_{AB}$ = 22.1 Hz, $J_{AB}$ = 12.2 Hz, 2 H), 6.79-6.82 (m, 2 H), 7.19-7.28 (m, 7 H); $^{13}C$ NMR ($CDCl_3$, 125 MHz) δ 28.2 (q'), 31.1 (q'), 37.4 (t'), 42.4 (s'), 55.3 (q'), 59.3 (d'), 60.2 (d'), 72.0 (t'), 73.1 (t'), 81.1 (s'), 113.8 (d'), 127.3 (d'), 127.4 (d'), 128.1 (d'), 128.4 (d'), 134.7 (s'), 138.1 (s'), 158.9 (s'), 172.3 (s'); exact mass *m/z* calcd for $C_{27}H_{40}NO_4S$ (M + H) 474.2678, found 474.2674.

Isomer **43.1s** had: $[\alpha]^{20}_{D}$ +22.2° (*c* 1.0, $CH_2Cl_2$); FTIR ($CH_2Cl_2$ cast) 1731 $cm^{-1}$; $^1H$ NMR ($CDCl_3$, 500 MHz) δ 1.27 (s, 9 H), 1.35 (s, 9 H), 2.50 (br s, 1 H), 2.73-2.80 (m, 2 H), 3.31 (t, *J* = 4.6 Hz, 1 H), 3.56-3.61 (m, 2 H), 3.73-3.61 (overlapping signals containing a singlet at δ 3.74, 4 H in all), 4.49 (ABq, $\Delta\nu_{AB}$ = 14.5 Hz, $J_{AB}$ = 12.1 Hz, 2 H), 6.78-6.81 (m, 2 H), 7.19-7.29 (m, 7 H); $^{13}C$ NMR ($CDCl_3$, 125 MHz) δ 28.1 (q'), 31.2 (q'), 36.4 (t'), 42.3 (s'), 55.3 (q'), 59.6 (d'), 60.4 (d'), 70.3 (t'), 73.3 (t'), 81.0 (s'), 113.8 (d'), 126.9 (d'), 127.5 (d'), 128.2 (d'), 128.4 (d'), 134.7 (s'), 138.0 (s'), 158.9 (s'), 171.9 (s'); exact mass *m/z* calcd for $C_{27}H_{40}NO_4S$ (M + H) 474.2678, found 474.2679.

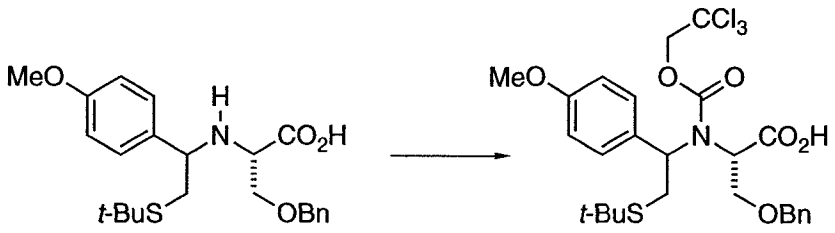
**(2*S*)-3-Benzyloxy-2-[2-*tert*-butylsulfanyl-1-(4-methoxyphenyl)ethylamino]propionic Acid (43.2f).**



**43.1f** **43.2f**

$Me_3SiOSO_2CF_3$ (323 μL, 1.79 mmol) was added dropwise to a stirred and cooled (0 °C) solution of ester **43.1f** (422 mg, 0.893 mmol) in dry $CH_2Cl_2$ (6.6 mL). Stirring was continued for 6 h without recharging the cold bath and the mixture was applied directly to a silica gel column (2 x 15 cm). Flash chromatography, using 4:100 MeOH-$CH_2Cl_2$, gave **43.2f** (338 mg, 90%) as a pale yellow solid: $[\alpha]^{20}_D$ +2.4° (*c* 1.0, MeOH); mp 172-176 °C; $^1$H NMR ($CDCl_3$, 500 MHz) δ 1.28 (s, 9 H), 2.81-2.89 (m, 2 H), 3.32-3.34 (m, 1 H), 3.47 (dd, $J$ = 9.9, 3.9 Hz, 1 H), 3.68-3.82 (m containing a singlet at δ 3.75, 5 H in all), 4.33 (ABq, $\Delta\nu_{AB}$ = 44.7 Hz, $J_{AB}$ = 11.8 Hz, 2 H), 6.76-6.79 (m, 2 H), 7.11-7.30 (m, 7 H); $^{13}$C NMR ($CDCl_3$, 125 MHz) δ 31.0 (q'), 35.6 (s'), 42.9 (t'), 55.3 (q'), 59.5 (d'), 62.5 (d'), 69.2 (t'), 73.0 (t'), 114.2 (d'), 127.6 (d'), 127.7 (d'), 128.2 (d'), 128.3 (d'), 137.3 (s'), 159.5 (s'), 172.3 (s'); exact mass *m/z* calcd for $C_{23}H_{32}NO_4S$ (M + H) 418.2047, found 418.2052.

**3-Benzyloxy-2-[[2-*tert*-butylsulfanyl-1-(4-methoxyphenyl)ethyl](2,2,2-trichloroethoxycarbonyl)-amino]propionic Acid (43.3f).**

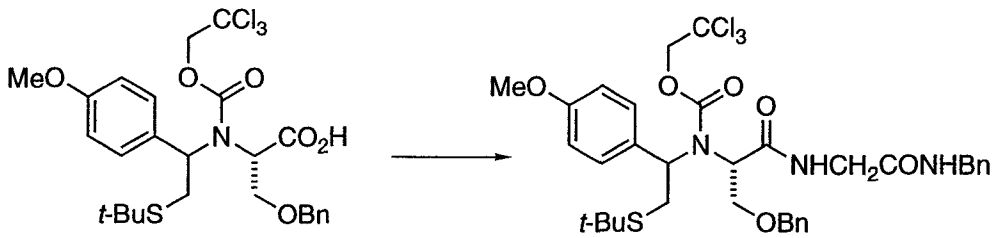


**43.2f** **43.3f**

A solution of $Cl_3CCH_2OCOCl$ (228 μL, 1.65 mmol) in dioxane (1 mL) and 0.5 N NaOH (430 μL, 215 mmol) were added simultaneously by syringe pump over 4.5 h to a stirred and cooled (0 °C) solution of **43.2f** (308 mg, 0.827 mmol) in 1 N NaOH (0.99 mL). When addition was complete the cold bath was removed and stirring was continued for 14 h. The mixture was diluted with water (5 mL), adjusted to pH 3-4 with 1 N hydrochloric acid, and extracted with $Et_2O$ (2 x 15 mL). The combined extracts were dried ($MgSO_4$) and evaporated. Flash chromatography of the residue over silica gel (2 x 25 cm), using 8:100 MeOH-$CH_2Cl_2$, gave **43.3f** (174 mg, 38%) as a white foam: $[\alpha]^{20}_D$ -34.5° (*c* 1.0, $CHCl_3$); FTIR ($CDCl_3$ cast) 1714 $cm^{-1}$; $^1H$ NMR ($CDCl_3$, 400 MHz) (mixture of rotamers) δ 1.22 (s, 3.9 H), 1.28 (s, 5.1 H), 2.93-3.01 (m, 1 H), 3.14-3.24 (m, 1 H), 3.75 (s, 3 H), 3.76-3.80 (m, 1 H), 3.88-3.96 (m, 1 H), 4.04-4.07 (m, 1 H), 4.46-4.58 (m, 2.6 H), 4.70-4.75 (m, 1 H), 4.94 (d, *J* = 11.9 Hz, 0.42 H), 5.42 (dd, *J* = 9.6, 6.4 Hz, 1

H), 6.81 (d, $J$ = 8.5 Hz, 2 H), 7.21-7.32 (m, 7 H); $^{13}C$ NMR ($CDCl_3$, 125 MHz) (mixture of rotamers) δ 29.6 (t'), 30.2 (t'), 30.9 (q'), 42.7 (s'), 43.0 (s'), 55.2 (q'), 56.7 (d'), 57.4 (d'), 60.4 (d'), 61.4 (d'), 68.3 (t'), 69.2 (t'), 73.5 (t'), 73.6 (t'), 75.1 (t'), 75.5 (t'), 94.6 (s'), 95.3 (s'), 113.7 (s'), 127.6 (s'), 127.62 (s'), 127.7 (d'), 127.8 (d'), 128.4 (d'), 130.6 (d'), 130.7 (d'), 137.4 (s'), 137.5 (s'), 153.2 (s'), 153.5 (s'), 159.3 (s'), 159.4 (s'), 173.5 (s'), 174.0 (s'); exact mass *m/z* calcd for $C_{26}H_{32}Cl_3NNaO_6S$ (M + Na) 614.0908, found 614.0904.

**[(2*S*)-1-[(Benzylcarbamoylmethyl)carbamoyl]-2-benzyloxyethyl][2-*tert*-butylsulfanyl-1-(4-methoxyphenyl)ethyl]carbamic Acid 2,2,2-Trichloroethyl Ester (43.4f).**



**43.3f** **43.4f**

$CF_3CO_2H.H_2NCH_2CONHBn$[45] (92 mg, 0.33 mmol) and $Et_3N$ (134 μL, 0.954 mmol) were added with stirring to dry MeCN (1 mL). Acid **43.3f** (174 mg, 0.318 mmol) and then 2-(1*H*-benzotriazol-1-yl)-1,1,3,3-tetramethyluronium hexafluorophosphate (109 mg, 0.331 mmol) were added. Stirring was continued for 12 h and

the mixture was diluted with EtOAc (20 mL) and washed successively with 1 N hydrochloric acid (2 x 15 mL) and saturated aqueous $NaHCO_3$ (2 x 15 mL). The organic phase was dried ($MgSO_4$) and evaporated. Flash chromatography of the residue over silica gel (2 x 20 cm), using 1:50 MeOH-$Et_2O$, gave **43.4f** (168 mg, 71%) as a white foam: $[\alpha]^{20}_D$ -36.5° (*c* 1, $CHCl_3$); FTIR ($CDCl_3$ cast) 3339 (br), 1713, 1692, 1663 $cm^{-1}$; $^1H$ NMR ($CDCl_3$, 500 MHz) δ 1.21 (br s, 9 H), 2.96-3.12 (m, 2 H), 3.42-3.48 (m, 1 H), 3.58-3.88 (m containing singlet at δ 3.74, 6 H in all), 4.20-4.30 (m, 2 H), 4.33-4.54 (m, 4 H), 4.68 (br s, 0.2 H), 5.41-5.47 (m, 1 H), 5.96 (br s, 0.2 H), 6.24 (br s, 0.5 H), 6.60 (br s, 0.3 H), 6.77-6.91 (m, 2 H), 7.19-7.34 (m, 13 H); $^{13}C$ NMR ($CDCl_3$, 125 MHz) (mixture of rotamers) δ 29.7 (t'), 29.9 (t'), 30.9 (q'), 42.9 (t'), 43.0 (t'), 43.2 (s'), 43.3 (t'), 55.2 (q'), 57.4 (d'), 57.9 (d'), 61.0 (d'), 61.2 (d'), 67.9 (t'), 73.5 (t'), 75.1 (t'), 75.2 (t'), 94.9 (s'), 114.0 (d'), 114.3 (d'), 127.2 (d'), 127.4 (d'), 127.5 (d'), 127.7 (d'), 127.9 (d'), 128.1 (d'), 128.4 (d'), 128.9 (d'), 129.6 (d'), 129.9 (d'), 137.2 (s'), 137.9 (s'), 153.4 (s'), 159.5 (s'), 159.6 (s'), 168.0 (s'), 168.4 (s'), 168.8 (s'), 169.0 (s'); exact mass *m/z* calcd for $C_{35}H_{42}Cl_3N_3NaO_6S$ (M + Na) 760.1752, found 760.1755.

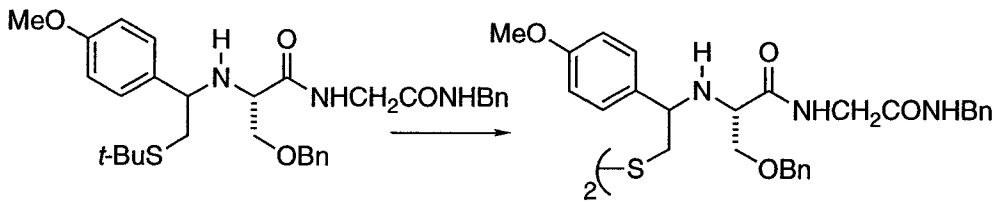
**43.4f** **43.5f**

Cd powder (591 mg, 5.26 mmol) was added in one portion to a stirred solution of **43.4f** (136 mg, 0.184 mmol) in 1:1 DMF-AcOH (4.0 mL). Stirring was continued for 11 h at room temperature, and the mixture was filtered through a Celite pad (2 x 4 cm), using EtOAc (50 mL). The combined filtrates and washings were evaporated, and the residue was adsorbed onto silica gel (5 g) from MeOH. The solid was applied to the top of a column of silica gel (2 x 20 cm), and flash chromatography, using 1:25 MeOH-$CH_2Cl_2$, gave **43.5f** (91.6 mg, 88%) as pale yellow resin: $[\alpha]^{20}_D$ -39.0° (*c* 1, MeOH); FTIR ($CDCl_3$ cast) 3306, 1659 $cm^{-1}$; $^1H$ NMR ($CDCl_3$, 400 MHz) δ 1.29 (s, 9 H), 2.63-2.72 (m, 3 H), 3.17 (dd, *J* = 5.7, 3.7 Hz, 1 H), 3.35 (dd, *J* = 9.5, 3.7 Hz, 1 H), 3.51 (dd, *J* = 8.8, 5.4 Hz, 1 H ), 3.62 (dd, *J* = 9.4, 5.8 Hz, 1 H), 3.76 (s, 3 H), 3.89 (dd, *J* = 16.5, 5.9 Hz, 1 H), 4.10-4.20 (m, 3 H), 4.27-4.39 (m, 2 H), 6.76 (d, *J* = 8.4 Hz, 2 H), 6.85 (s, 1 H), 7.02 (d, *J* = 8.6 Hz, 2 H), 7.12-7.32 (m, 10 H), 8.44 (t, *J* = 6.5

Hz, 1 H); $^{13}C$ NMR ($CDCl_3$, 100 MHz) δ 31.0 (q'), 36.7 (s'), 42.7 (t'), 43.1 (t'), 43.4 (t'), 55.2 (q'), 59.7 (d'), 62.1 (d'), 71.0 (t'), 72.7 (t'), 114.0 (d'), 127.3 (d'), 127.4 (d'), 127.5 (d'), 127.8 (d'), 128.4 (d'), 128.5 (d'), 134.0 (s'), 137.4 (s'), 138.0 (s'), 159.1 (s'), 169.1 (s'), 173.3 (s'); exact mass *m/z* calcd for $C_{32}H_{42}N_3O_4S$ 564.2890 (M + H), found 564.2896.

**(2*S*)-*N*-(Benzylcarbamoylmethyl)-2-[2-[2-[1-[(benzylcarbamoylmethyl)carbamoyl]-2-benzyloxyethyl-amino]-2-(4-methoxyphenyl)ethyldisulfanyl]-1-(4-methoxyphenyl)ethylamino]-3-benzyloxypropionamide (43.6f).**



**43.5f** **43.6f**

In this experiment the initial thiol product was not protected from air, and the compound isolated was the corresponding disulfide **43.6f**. We did not establish if oxidation occurred before or after flash chromatography.

$CF_3CO_2H$ (2 mL) was added to thioether **43.5f** (85.0 mg, 0.153 mmol) contained in a flask immersed in an ice-bath. The mixture was stirred and PhOMe (32 μL), followed by

$Hg(OAc)_2$ (50.5 mg, 0.158 mmol) were added. Stirring was continued for 25 min and the solvent was evaporated. The residue was dissolved in MeCN (20 mL) and $H_2S$ gas was bubbled through the solution for 2 min. The resulting black suspension was filtered through a tightly packed Celite column (2 x 4 cm) and the solid was washed with several portions of MeCN. Evaporation of the combined filtrate and washings, and flash chromatography of the residue over silica gel (2 x 18 cm), using 4:100 MeOH-$CH_2Cl_2$, gave disulfide **43.6f** (44.4 mg, 58%) as a thick oil: $[\alpha]^{20}_D$ -47.7°; FTIR ($CDCl_3$ cast) 3300, 1665, 1608 $cm^{-1}$; $^1H$ NMR ($CDCl_3$, 400 MHz) δ 1.58 (br s, 1 H), 2.33 (br s, 1 H), 2.85 (d, *J* = 6.2 Hz, 1 H), 3.20-3.23 (m, 1 H), 3.37-3.41 (m, 1 H), 3.57-3.61 (m, 1 H), 3.71-3.81 (m containing a singlet at δ 3.76, 4 H in all), 3.86-4.10 (m, 2 H), 4.16-4.43 (m, 4 H), 6.76-6.79 (m, 3 H), 6.96-7.03 (m, 2 H), 7.12-7.38 (m, 10 H), 8.14 (br s, 1 H); $^{13}C$ NMR ($CDCl_3$, 125 MHz) δ 32.2 (t'), 43.1 (t'), 43.4 (t'), 55.2 (q'), 59.7 (d'), 60.4 (d'), 63.4 (d'), 70.8 (t'), 72.7 (t'), 72.8 (t'), 73.0 (t'), 114.0 (d'), 114.1 (d'), 114.3 (d'), 127.4 (d'), 127.5 (d'), 127.7 (d'), 127.8 (d'), 127.9 (d'), 128.4 (d'), 128.5 (d'), 128.6 (d'), 128.7 (s'), 132.0 (s'), 137.4 (s'), 138.0 (s'), 159.2 (s'), 168.8 (s'), 172.9 (s'); exact mass *m/z* calcd for $C_{56}H_{65}N_6O_8S_2$ 1013.4305 (M + H), found 1013.4301.

**(2*S*)-3-Benzyloxy-2-[2-*tert*-butylsulfanyl-1-(4-methoxyphenyl)ethylamino]propionic Acid (44.1s).**

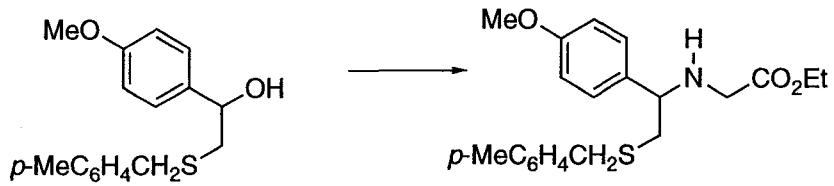
**[1-(4-Methoxyphenyl)-2-(4-methylbenzylsulfanyl)-ethylamino]acetic Acid Ethyl Ester (46.1).**

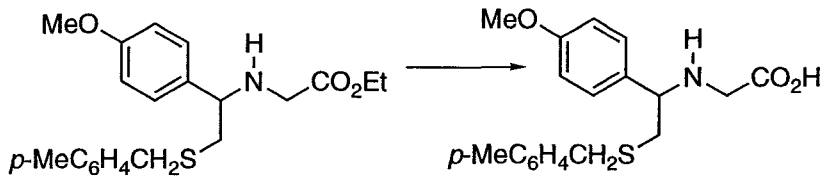


**45.5** **46.1**

$Me_3SiBr$ (99 μL, 0.74 mmol) was injected in one portion to a stirred and cooled (0 °C) solution of alcohol **45.5** (204 mg, 0.710 mmol) in dry $CH_2Cl_2$ (2 mL). Stirring was continued at 0 °C for 0.5 h and neat, freshly distilled (distilled under water pump vacuum) $H_2NCH_2CO_2Et$ (146 mg, 1.42 mmol) was added in one portion. The cold bath was removed and stirring was continued for 3 h. The mixture was adsorbed onto silica gel (2 g) from $CH_2Cl_2$. The solid was applied to the top of a column of silica gel (1.5 x 15 cm), and flash chromatography, using 1:6 EtOAc-hexanes, gave **46.1** (224 mg, 84%) as a colorless oil: FTIR ($CHCl_3$ cast) 3310 (br), 1735 $cm^{-1}$; $^1H$ NMR ($CDCl_3$, 300 MHz) δ 1.23 (t, $J$ = 7.1 Hz, 3 H), 2.30 (s, 3 H), 2.54 (dd, $J_{AB}$ = 13.6 Hz, $J_{AX}$ = 9.2 Hz, 1 H), 2.56-2.60 (br s, 1 H), 2.65 (dd, $J_{AB}$ = 13.6 Hz, $J_{BX}$ = 4.6 Hz, 1 H), 3.18 (ABq, $\Delta\nu_{AB}$ = 52.9, $J_{AB}$ = 17.5 Hz, 2 H), 3.63-3.73 (m, 3 H), 3.76 (s, 3 H), 4.15 (q, $J$ = 7.1 Hz, 2 H), 6.80-6.85 (m, 2 H),

7.07-7.10 (m, 2 H), 7.15-7.20 (m, 4 H); $^{13}C$ NMR ($CDCl_3$, 125 MHz) δ 14.2 (q'), 21.1 (q'), 35.5 (t'), 39.3 (t'), 48.4 (t'), 55.2 (q'), 59.7 (d'), 60.5 (t'), 113.8 (d'), 128.2 (d'), 128.7 (d'), 129.0 (d'), 133.8 (s'), 134.9 (s'), 136.4 (s'), 158.9 (s'), 172.2 (s'); exact mass *m/z* calcd for $C_{21}H_{27}NO_3S$ 373.1712, found 373.1704.

**[1-(4-Methoxyphenyl)-2-(4-methylbenzylsulfanyl)-ethylamino]acetic Acid Ethyl Ester (46.2).**

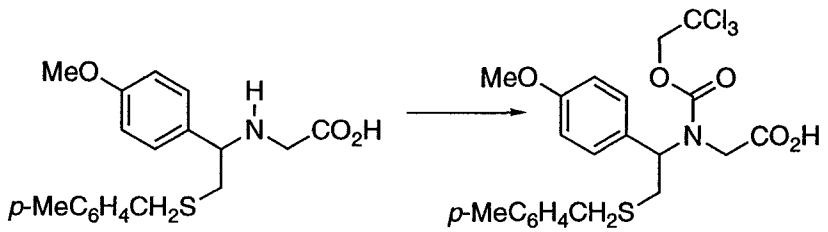


**46.1** **46.2**

Aqueous NaOH (1N, 1.80 mL) was added to a stirred solution of ester **46.1** (424 mg, 0.880 mmol) in 1:1 water-dioxane (16 mL). Stirring was continued for 4 h, the mixture was acidified with 1 N hydrochloric acid, the solvent was evaporated and the residue was mixed with MeOH (5 mL), and adsorbed onto silica gel (3 g). The solid was applied to the top of a column of silica gel (1.5 x 15 cm), and flash chromatography, using 1:2:25 AcOH-MeOH-$CH_2Cl_2$, gave **46.2** (277 mg, 91%) as white solid: mp 165-169 °C; FTIR (microscope) 1609 $cm^{-1}$; $^1H$ NMR ($CD_3CO_2D$, 400 MHz) δ 1.53 (s, 1 H), 2.28 (s, 3 H), 2.97-3.02 (m, 1 H), 3.18-3.24 (m, 1 H), 3.63 (br s, 2 H), 3.68 (s, 2 H), 3.79 (s, 3 H), 4.36-4.40 (m, 1 H), 6.97

(d, $J$ = 8.1 Hz, 2 H), 7.13 (ABq, $\Delta\nu_{AB}$ = 32.7 Hz, $J_{AB}$ = 7.8 Hz, 4 H), 7.40 (d, $J$ = 8.2 Hz, 2 H); $^{13}$C NMR ($CD_3CO_2D$, 100 MHz) δ 21.1 (q'), 34.8 (t'), 36.3 (t'), 55.8 (q'), 62.5 (d'), 115.7 (d'), 125.7 (s'), 130.0 (d'), 130.3 (d'), 131.1 (d'), 135.5 (s'), 138.0 (s'), 162.0 (s'); exact mass *m/z* calcd for $C_{19}H_{23}NNaO_3S$ 368.1296 (M + Na), found 368.1298.

**[[1-(4-Methoxyphenyl)-2-(4-methylbenzylsulfanyl)-ethyl](2,2,2-trichloroethoxycarbonyl)amino]acetic Acid (46.3).**

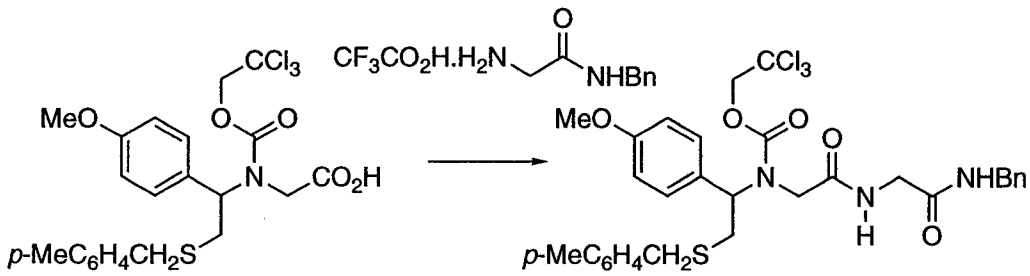


**46.2** **46.3**

Neat $Cl_3CCH_2OCOCl$ (220 μL, 1.61 mmol) and 1 N NaOH (210 μL) were added simultaneously by syringe over 4.5 h to a stirred and cooled (0 °C) suspension of **46.2** (277 mg, 0.805 mmol) in 1 N NaOH (0.97 mL) and dioxane (1 mL). When addition was complete the cold bath was removed and stirring was continued for 11 h, by which time all **46.2** had reacted. The acidic mixture was extracted with $Et_2O$ and the combined extracts were dried ($MgSO_4$) and evaporated. Flash chromatography of the residue over silica gel (2 x 15 cm), using 4:100 MeOH-$CH_2Cl_2$, gave **46.3** (314 mg, 74%) as an oil:

FTIR ($CDCl_3$ cast) 1716, 1611 $cm^{-1}$; $^1H$ NMR ($CDCl_3$, 400 MHz) δ 2.30 (s, 3 H), 2.94-3.02 (m, 2 H), 3.69 (s, 2 H), 3.70-3.73 (m, 2 H), 3.77 (s, 3 H), 4.72-4.95 (m, 2 H), 5.42-5.49 (m, 1 H), 6.82-6.86 (m, 2 H), 7.07-7.10 (m, 2 H), 7.14-7.20 (m, 4 H); $^{13}C$ NMR ($CDCl_3$, 100 MHz) (mixture of rotamers) δ 21.1 (q'), 32.2 (t'), 32.8 (t'), 36.5 (t'), 44.6 (t'), 45.2 (t'), 55.2 (q'), 58.2 (d'), 58.5 (d'), 67.0 (t'), 75.5 (t'), 76.7 (t'), 95.2 (s'), 114.1 (d'), 128.6 (s'), 128.9 (d'), 129.2 (d'), 129.4 (d'), 129.5 (d'), 129.6 (d'), 134.6 (s'), 134.7 (s'), 136.7 (s'), 136.9 (s'), 154.3 (s'), 154.4 (s'), 159.6 (s'), 173.3 (s'), 173.8 (s'); exact mass *m/z* calcd for $C_{22}H_{24}Cl_3NNaO_5S$ 542.0338 (M + Na), found 542.0335.

**[[(Benzylcarbamoylmethyl)carbamoyl]methyl][1-(4-methoxyphenyl)-2-(4-methylbenzylsulfanyl)ethyl]-carbamic Acid 2,2,2-Trichloroethyl Ester (46.4).**

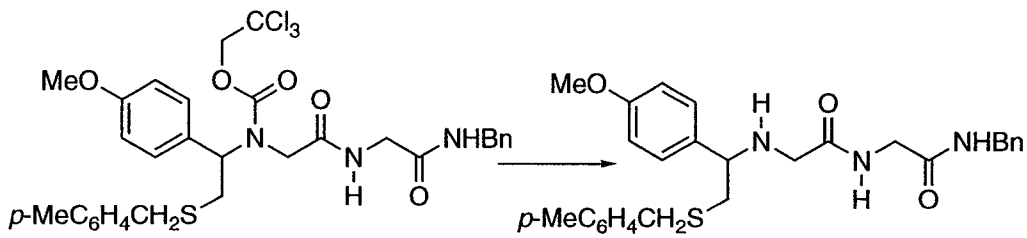


**46.3** **46.4**

*i*-$Pr_2NEt$ (115 μL, 0.664 mmol) was added to a stirred and cooled (0 °C) mixture of acid **46.3** (314 mg, 0.603 mmol) and $CF_3CO_2H.H_2NCH_2CONHBn$[45] (184 mg, 0.664 mmol) in dry $CH_2Cl_2$ (5

mL). After 5 min EDCI (127 mg, 0.664 mmol) was added, followed by DMAP (3 mg), and the mixture was stirred for 3.5 h without recharging the cold bath. The mixture was diluted with EtOAc (15 mL) and washed successively with 1 N hydrochloric acid (3 mL) and brine (2 x 5 mL), dried ($MgSO_4$) and evaporated. Flash chromatography of the residue over silica gel (2 x 20 cm), using 4:100 MeOH-$CH_2Cl_2$, gave **46.4** (296 mg, 73%) as a white foam: FTIR ($CH_2Cl_2$ cast) 3306 (br), 1693, 1659 $cm^{-1}$; $^1H$ NMR ($CDCl_3$, 500 MHz) $\delta$ 2.29 (s, 3 H), 2.87-3.01 (m, 2 H), 3.47-3.97 (m containing a singlet at $\delta$ 3.74, 9 H in all), 4.29-4.45 (m, 2 H), 4.64-4.71 (m, 1 H), 5.38-5.42 (m, 1 H), 6.43 (br s, 1 H), 6.79 (d, $J$ = 8.0 Hz, 2 H), 6.92 (br s, 1 H), 7.03-7.28 (m, 12 H); $^{13}C$ NMR ($CDCl_3$, 125 MHz) (mixture of rotamers) $\delta$ 21.1 (q'), 32.4 (t'), 32.7 (t'), 35.7 (t'), 35.9 (t'), 42.6 (t'), 43.0 (t'), 43.3 (t'), 43.8 (t'), 47.5 (t'), 47.9 (t'), 55.3 (q'), 57.9 (d'), 58.4 (d'), 75.0 (t'), 75.3 (t'), 94.9 (s'), 95.2 (s'), 114.3 (d'), 127.4 (d'), 127.5 (d'), 127.6 (d'), 127.7 (d'), 127.8 (d'), 128.4 (d'), 128.5 (d'), 128.6 (d'), 128.7 (d'), 128.8 (d'), 128.9 (s'), 129.2 (d'), 129.3 (d'), 133.9 (s'), 134.1 (s'), 136.8 (s'), 137.1 (s'), 137.7 (s'), 137.9 (s'), 154.7 (s'), 155.1 (s'), 159.5 (s'), 168.1 (s'), 168.4 (s'), 168.8 (s'), 169.3 (s'); exact mass *m/z* calcd for $C_{31}H_{34}Cl_3N_3NaO_5S$ 688.1182 (M + Na), found 688.1183.

***N*-(Benzylcarbamoylmethyl)-2-[1-(4-methoxyphenyl)-2-(4-methylbenzylsulfanyl)ethylamino]acetamide (46.5).**



**46.4** **46.5**

Cd powder (1.50 g, 13.3 mmol) was added in one portion to a stirred solution of **46.4** (296 mg, 0.444 mmol) in 1:1 DMF-AcOH (9.6 mL). Stirring was continued for 6 h at room temperature, and the mixture was filtered through a Celite pad (2 x 4 cm), using EtOAc (75 mL). The combined filtrates and washings were washed with saturated aqueous $NaHCO_3$ (2 x 15 mL), dried ($MgSO_4$), and evaporated. Flash chromatography of the residue over silica gel (2 x 15 cm), using 2:100 and then 1:10 MeOH-$CH_2Cl_2$, gave **46.5** (204 mg, 93%) as a pale yellow oil: FTIR ($CDCl_3$ cast) 3296, 1654 $cm^{-1}$; $^1H$ NMR ($CDCl_3$, 500 MHz) δ 2.29 (s, 3 H), 2.62 (d, *J* = 6.6 Hz, 2 H), 2.90 (br s, 1 H), 3.04-3.13 (m, 2 H), 3.48 (br t, *J* = 6.7 Hz, 1 H), 3.61-3.75 (m containing a singlet at δ 3.72, 5 H in all), 3.86 (d, *J* = 5.0 Hz, 2 H), 4.36 (d, *J* = 5.6 Hz, 2 H), 6.76-6.81 (m, 3 H), 7.01-7.25 (m, 11 H), 7.73 (br s, 1 H); $^{13}C$ NMR ($CDCl_3$, 100 MHz) δ 21.1 (q'), 36.3 (t'), 38.9 (t'), 43.2 (t'), 43.4 (t'), 49.6 (t'), 55.2 (q'), 60.9 (d'), 114.1 (d'), 127.3 (d'), 127.5 (d'), 127.6 (), 127.8 (d'), 127.9 (d'), 128.0

(d'), 128.6 (d'), 128.7 (d'), 128.8 (d'), 129.2 (d'), 133.0 (s'), 124.5 (s'), 136.8 (s'), 137.9 (s'), 159.2 (s'), 168.6 (s'), 172.5 (s'); exact mass *m/z* calcd for $C_{28}H_{33}N_3NaO_3S$ (M + Na) 514.2140, found 514.2144.

## X-Ray Crystallography Laboratory

## STRUCTURE REPORT

**XCL Code:** DLC0005
**Date:** 1 June 2000

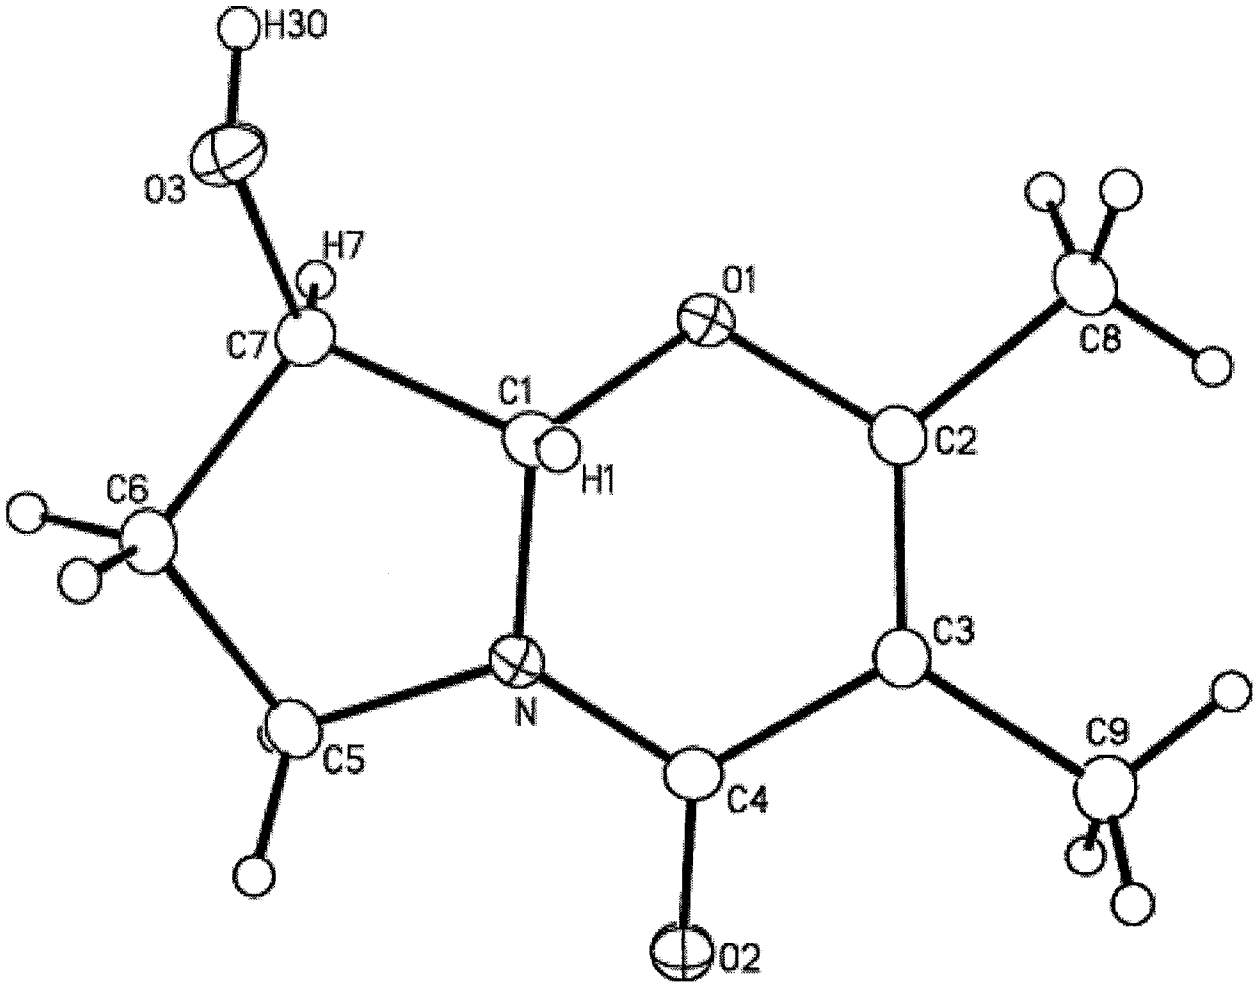
**Compound:** 3,4-Dimethyl-7-hydroxy-1-aza-5-oxobicyclo[4.3.0]non-3-en-2-one
**Formula:** $C_9H_{13}NO_3$

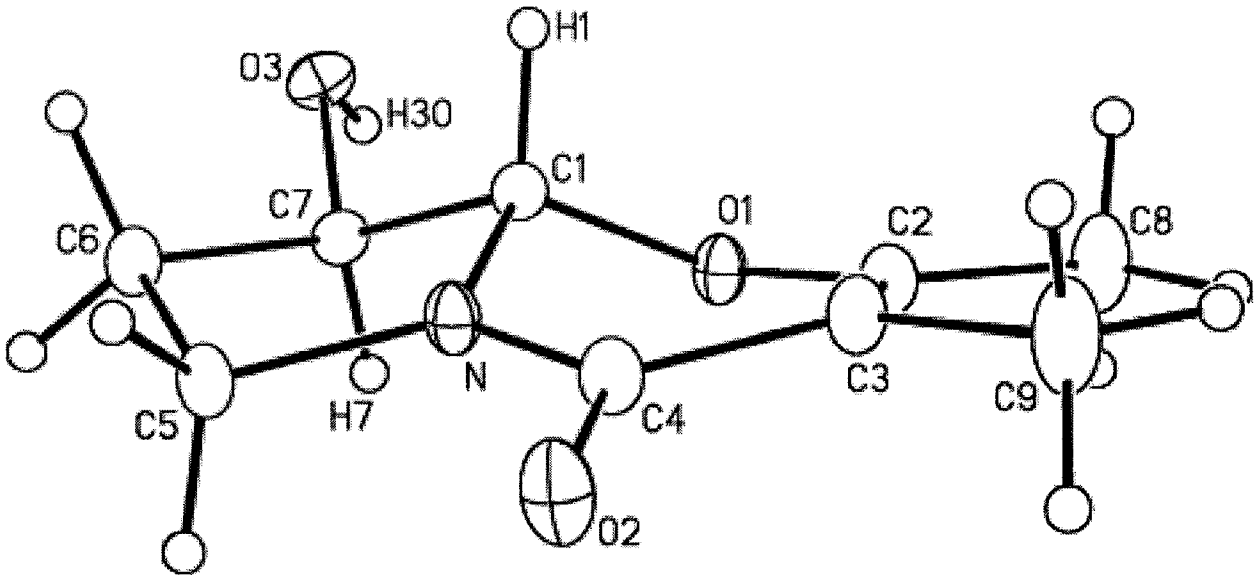
**Supervisor:** D. L. J. Clive **Crystallographer:** R. McDonald

## Figure Legends

**Figure 1.** Perspective view of the 3,4-dimethyl-7-hydroxy-1-aza-5-oxobicyclo[4.3.0]non-3-en-2-one molecule showing the atom labelling scheme. Non-hydrogen atoms are represented by Gaussian ellipsoids at the 20% probability level. Hydrogen atoms are shown with arbitrarily small thermal parameters.

**Figure 2.** Alternate view of the molecule.





## List of Tables

**Table 1.** Crystallographic Experimental Details

| | |
|---|---|
| *A. Crystal Data* | |
| formula | $C_9H_{13}NO_3$ |
| formula weight | 183.20 |
| crystal dimensions (mm) | 0.38 × 0.24 × 0.16 |
| crystal system | monoclinic |
| space group | $P2_1/c$ (No. 14) |
| unit cell parameters[a] | |

**Table 1.** Crystallographic Experimental Details (continued)

[c]Sheldrick, G. M. *Acta Crystallogr.* **1990**, *A46*, 467–473.

[d]Sheldrick, G. M. *SHELXL-93*. Program for crystal structure determination. University of Göttingen, Germany, 1993. Refinement on $F_o^2$ for all reflections (all of these having $F_o^2 \geq -3\sigma(F_o^2)$). Weighted $R$-factors $wR_2$ and all goodnesses of fit $S$ are based on $F_o^2$; conventional $R$-factors $R_1$ are based on $F_o$, with $F_o$ set to zero for negative $F_o^2$. The observed criterion of $F_o^2 > 2\sigma(F_o^2)$ is used only for calculating $R_1$, and is not relevant to the choice of reflections for refinement. $R$-factors based on $F_o^2$ are statistically about twice as large as those based on $F_o$, and $R$-factors based on ALL data will be even larger.

[e]$F_c^* = kF_c[1 + x\{0.001F_c^2\lambda^3/\sin(2\theta)\}]^{-1/4}$ where $k$ is the overall scale factor.

[f]$S = [\Sigma w(F_o^2 - F_c^2)^2/(n-p)]^{1/2}$ ($n$ = number of data; $p$ = number of parameters varied; $w = [\sigma^2(F_o^2) + (0.0555P)^2 + 0.2082P]^{-1}$ where $P = [\text{Max}(F_o^2, 0) + 2F_c^2]/3$).

[g]$R_1 = \Sigma||F_o| - |F_c||/\Sigma|F_o|$; $wR_2 = [\Sigma w(F_o^2 - F_c^2)^2/\Sigma w(F_o^4)]^{1/2}$.

**Table 2.** Atomic Coordinates and Equivalent Isotropic Displacement Parameters

| Atom | *x* | *y* | *z* | $U_{eq}$, Å$^2$ |
